PUBLICATIONS ABSTRACTED

Technical Bulletin—

	Page
531. Bud Selection in Eureka and Lisbon Lemons and Progeny Tests of Bud Variations, A. D. Shamel, C. S. Pomeroy, and R. E. Caryl.	48
536. Crop Rotation and Tillage Experiments at the Northern Great Plains Field Station, Mandan, N. Dak., J. T. Sarvis and J. C. Thysell.	773
537. Growth of Douglas Fir Trees of Known Seed Source, T. T. Munger and W. G. Morris.	51
538. Effect of Method and Rate of Grazing on Beef Production and Plant Population of Pastures at Beltsville, Md., M. A. Hein and A. C. Cook.	220
543. Blast-Furnace Processes for the Production of Phosphatic and Potassic Fertilizer Materials, P. H. Royster, K. G. Clark, T. P. Hignett, L. E. Bowe, H. I. Lansdon, J. C. Southard, and J. W. Turrentine.	452
544. Yield of Even-Aged Stands of Sitka Spruce and Western Hemlock, W. H. Meyer.	492
545. Methods for the Measurement of Certain Character Properties of Raw Cotton, H. B. Richardson, T. L. W. Bailey, Jr., and C. M. Conrad.	329
546. Structure, Occurrence, and Properties of Compression Wood, M. Y. Pillow and R. F. Luxford.	52
547. Effect of Different Methods of Grazing on Native Vegetation and Gains of Steers in Northern Great Plains, W. H. Black, A. L. Baker, V. I. Clark, and O. R. Mathews.	377
548. Control of Southern Celery Mosaic in Florida by Removing Weeds That Serve as Sources of Mosaic Infection, F. L. Wellman.	498
549. Drought Survival of Native Grass Species in the Central and Southern Great Plains, 1935, D. A. Savage.	775
550. Protection of Apples and Pears in Transit From the Pacific Northwest During the Winter Months, E. D. Mallison, E. A. Gorman, Jr., and W. V. Hukill.	486
551. Forest Fire Insurance in the Pacific Coast States, H. B. Shepard.	52
552. Trace Elements in the Soils From the Erosion Experiment Stations, With Supplementary Data on Other Soils, C. S. Slater, R. S. Holmes, and H. G. Byers.	14
553. Effect of Temperature, Humidity, and Other Factors on Hatch of Hens' Eggs and on Energy Metabolism of Chick Embryos, H. G. Barott.	381
554. Rapid Determination of Oil Content and Oil Quality in Flaxseed, L. Zeleny and D. A. Coleman.	7
555. Marketing Onions, J. W. Park.	718
556. Soil Conservation Reconnaissance Survey of the Southern Great Plains Wind-Erosion Area, A. H. Joel.	18
558. Soil and Water Conservation Investigations, G. W. Musgrave and R. A. Norton.	707
559. Influence of Packing and Handling Methods on Condition of Apples Barreled for Export, P. L. Harding, J. M. Lutz, and D. H. Rose.	485

Technical Bulletin—Continued.

EXPERIMENT STATION RECORD

VOL. 77

JULY 1937

No. 1

THE RETIREMENT OF DIRECTORS LINFIELD AND WILLIAMS

The list of 1937 changes in the leadership of the State experiment stations will soon be further lengthened by the retirement from the directorship of two workers of long service and wide influence. These are Directors F. B. Linfield of Montana and C. G. Williams of Ohio.

Director Linfield, a native of Newfoundland and a graduate of Toronto University, began his work in the United States as professor of animal industry in the Utah Agricultural College in 1893 and 2 years later also became dairyman of the Utah station. In 1902 he went to Montana, originally as professor of agriculture and animal husbandman of the station. He was appointed director in 1904 and has also served as dean of the department of agriculture in the college since 1913.

Thus his service in the mountain region has extended over 44 years, a record well-nigh contemporaneous with agricultural investigation there and for much of the region even with agricultural settlement. He has been closely identified with its development, and he has long been regarded as one of its foremost leaders and as an authority upon matters pertaining to its welfare. Fortunately, although he is relinquishing the leadership of the station on September 1, he will continue to serve as director emeritus in charge of publications so that his experience and wide counsel will still be available. He will be succeeded as dean and director by Vice Dean Clyde McKee, and he, in turn, by A. H. Post, associate agronomist, as head of the department of agronomy.

Director Williams entered the field of experiment station work at the age of 40, but has completed 34 years in the exclusive service of the Ohio Experiment Station. Originally appointed as agronomist and farm superintendent in 1903, he became widely known as an outstanding agronomist and department head and in 1921 was appointed to succeed the late Director Charles E. Thorne in the leadership of the station. In this capacity he has not only maintained the high standards of the institution but has brought about

an increased development in various lines, notably the social sciences and in closer relationships with Ohio State University. In these ways and others he has broadened and strengthened the work of the station and extended its usefulness and influence. He will be succeeded on July 1 by Edmund Secrest, chief of the department of forestry and associate director since 1921.

REGIONAL RESEARCH LABORATORY FOR SWINE IMPROVEMENT

The fourth of the regional research laboratories organized under the Bankhead-Jones Act is now in operation. Known as the Regional Research Laboratory for Improvement of Swine Through the Application of Breeding Methods, it is located at the Iowa State College, where it will serve as the headquarters for the regional program of cooperation between the Federal Department of Agriculture and the experiment stations of the Corn Belt. The unit will be under the supervision of Dr. Hugh C. McPhee, Chief of the Animal Husbandry Division of the U. S. D. A. Bureau of Animal Industry, with Dr. William A. Craft in charge of the Ames Laboratory.

Authorized late in 1936, several projects have now been definitely approved and work is in progress not only in Iowa but also in Missouri and Nebraska. In Iowa the aim is to study various degrees of intensity of inbreeding with the Poland-China, and in Nebraska two types of modified inbreeding with the Duroc-Jersey. Missouri also will investigate modified inbreeding with the Poland-China, with a phase of crossbreeding as a measure of the transmission of characters by the sire.

As in the case of the previously established regional research laboratories (E. S. R., 75, p. 1), these including vegetable breeding in South Carolina, soybeans in Illinois, and grass breeding and pasture improvement in Pennsylvania, rapidity of development is contingent upon a number of factors, not the least of which is the amount of funds which are available. Should the increases contemplated by the Bankhead-Jones Act (E. S. R., 73, p. 289) be forthcoming for the fiscal year 1938, additional expansion and extension to other institutions will doubtless receive early consideration.

RECENT WORK IN AGRICULTURAL SCIENCE

AGRICULTURAL AND BIOLOGICAL CHEMISTRY

A textbook of biochemistry, edited by B. HARROW and C. P. SHERWIN (*Philadelphia and London: W. B. Saunders Co., 1935, pp. 797, figs. 52*).—"Biochemistry . . . has become so encyclopedic in its scope, that it seems an impossible task for any one individual to write an adequate textbook. It is for this reason that we have asked specialists in the various fields of biochemistry to contribute the chapters constituting this book. . . . Three chapters, not usually included in biochemical texts, have been added. The chapter on the cell, it seems to us, is as logical an introduction to biochemistry as a chapter on the atom would be to chemistry. The articles on immunochemistry and the chemistry of bacteria represent new and fertile fields for the expansion of knowledge."

The titles and authors of the 30 chapters of the text proper are as follows: The living cell, by R. Chambers; the carbohydrates, by R. S. Tipson and E. T. Stiller; the neutral fats and related substances, by W. M. Sperry; sterols, bile acids and related compounds, by H. Sobotka; the proteins, by R. H. A. Plimmer; some aspects of the physical chemistry of amino acids and proteins, by C. L. A. Schmidt; the nucleic acids, by R. S. Tipson; nutrition, by E. V. McCollum; the vitamins, by J. O. Drummond; enzymes and digestion, both by I. S. Kleiner; the biochemistry of bacteria, yeasts, and molds, by P. W. Clutterbuck and H. Raistrick; detoxication, by A. M. Ambrose and C. P. Sherwin; immunochemistry, by M. Heidelberger; blood, by J. H. Ferguson; the carriage of the blood gases and the acid-base equilibrium of the blood and respiration and respiratory metabolism, both by H. E. Himwich; animal pigments, by C. S. Leonard; oxidations and reductions, by B. Cohen; carbohydrate metabolism, by C. F. and G. T. Cori; lipid metabolism, by W. R. Bloor; the metabolism of proteins and amino acids, by J. M. Luck; mineral metabolism, by A. T. Shohl; bone and teeth, by J. Knaggs; function of water in the organism, by L. G. Rowntree; the chemistry of muscle, by P. Eggleton; the chemistry of the integument and urine, both by W. Morse; the biochemistry of the brain, by I. H. Page; and hormones, by B. Harrow. A bibliographic index and an index of subjects complete the volume.

The chemistry of milk, W. L. DAVIES (*London: Chapman & Hall, 1936, pp. XII+522, figs. 26*).—"This book . . . is an attempt to gather together in a concise, ordered form, the results of all the relevant and reliable investigation on the chemistry of milk", including that of milk processing, and contains 5 sections and 22 chapters. Part 1, the composition of milk, deals with introductory and general considerations and special variations. Part 2, the constituents of milk, considers milk fat, milk sugar, the protein (casein, lactalbumin, lactoglobulin) and nonprotein nitrogenous constituents, the mineral constituents, the enzymes, and the minor constituents of milk. Part 3 takes up the physical chemistry of milk, including general physical properties, acid-base equilibria, and the coagulation of milk. Part 4 deals with the chemistry of milk processing, the effect of heat on milk, milk and metals, the chemical

technology of milk condensing, and dried milk products. Part 5, the nutritive value of milk, considers the nutritional value of the major constituents of milk, the vitamins, and the nutritive value of milk as a whole.

Fruit jellies.—IX, The rôle of pectin.—5, The enzymic hydrolysis of starch in the presence of pectin, in pectic extracts, and in apple pomace, G. L. BAKER (*Delaware Sta. Bul.* 204 (1936), pp. 89, figs. 15).—In addition to the information previously obtained in this investigation (*E. S. R.*, 71, p. 293; 76, p. 581), are the following observations:

Enzymic activity upon a substrate at pH 3.5 containing starch and pectin proceeds according to the multimolecular reaction formula. On substrates of pectin only, the enzymic effects of the commercial diastatic preparations are least detrimental at lower pH values. As judged by viscosity measurements, the pectin solutions are more stable in a pH range of from 3.2 to 3.8. Excessive amounts of enzyme preparation added to pectin solutions cause depolymerization and decomposition to simpler substances soluble in alcohol.

"Diastatic hydrolysis of apple starch in pectic extracts should be carried to a point where a brown starch-iodine test is obtained in order to remove the possibility of cloudiness in jelly products due to starch. . . Heating dried apple pomace in water solution at 80° C. renders the apple starch present hydrolyzable by the diastatic enzyme preparations. Hydrolysis by diastatic enzyme preparations of the apple starch in dried pomace previous to extraction of pectin gives clear pectic liquors of low starch content without loss of jelly units. Small amounts of starch are removed, and increasing clarity is obtained, by extracting pectin at a low pH and allowing the extracts to stand at the extraction pH. Concentrations of pectin as well as apple starch in pectic extracts affect solution clarity. Hydrolysis of starch in pomace simplifies processing of extracted liquor. The adjustment of pH for enzymic treatment, the enzymic treatment, the usual inactivating procedure, and one filtration operation are no longer necessary.

"Freshly pressed pomace was leached with hot water and the apple starch hydrolyzed by enzymic treatment. The resulting dried product gave extracts twice as clear and containing less than 10 percent as much starch in solution as extracts from untreated pomace. No loss of jelly units results from the enzymic removal of starch in this manner."

The gum from lemon trees, E. ANDERSON, F. H. RUSSELL, and L. W. SEIGLE (*Jour. Biol. Chem.*, 113 (1936), No. 3, pp. 683-690).—This is a joint contribution from the Carnegie Institution of Washington, Stanford University, and the University of Arizona. The work forms part of a more general inquiry into the nature of the polyuronides of lemon wood.

The gum dealt with in the present paper is a pathological product, and is "a brownish-yellow translucent solid which can be ground to a powder. It has a faint odor but is almost tasteless. It dissolves in 3 parts of cold water to form a viscous solution. When very concentrated solutions of the gum are heated, they often form a semisolid gel. The gum does not reduce Fehling's solution until after it has been hydrolyzed by hot dilute acids. It consists of a uronic acid to which is attached an ether-linked methoxyl group. The aldehyde group of the uronic acid is attached by a glucosidic linkage to a series of molecules of *d*-galactose. The latter are attached by glucosidic linkages to a series of molecules of *l*-arabinose. The composition of the purified gum corresponds to 1 molecule of a methylated uronic acid plus 2 molecules of *d*-galactose plus 2 molecules of *l*-arabinose minus 5 molecules of water. Since, however, salts were obtained in which 1 molecule of a methylated uronic acid is combined, respectively, with 1, 2, 3, and 4 molecules of *d*-galactose, it appears that this simple formula must be doubled. This would indicate that

the gum consists of 2 molecules of a methylated uronic acid plus 4 molecules of *d*-galactose plus 4 molecules of *l*-arabinose minus 10 molecules of water."

The chemistry of lignin.—X, Lignin from oat straw, M. PHILLIPS and M. J. Goss (*Jour. Biol. Chem.*, 114 (1936), No. 2, pp. 557-565).—In an investigation carried out at the U. S. D. A. Bureau of Chemistry and Soils, three lignin fractions were isolated from oat straw by extracting it successively and exhaustively, first with a 2-percent alcoholic sodium hydroxide solution at room temperature, then (under reflux) with a 4-percent aqueous sodium hydroxide solution, and finally with fuming hydrochloric acid.

"The composition of the first lignin fraction agreed with that represented by the formula $C_{60}H_{40}O_{20}$. Four methoxyl groups and four hydroxyl groups were found to be present. Of the four hydroxyl groups, two could be methylated with diazomethane, thus indicating that these are more acidic, possibly phenolic or enolic in character. When fused with potassium hydroxide, protocatechuic acid was obtained. The yield was approximately 4 percent of the weight of the lignin. The analytical results on the second lignin fraction are more in agreement with that represented by the formula $C_{60}H_{40}O_{20}$. In this lignin fraction, approximately four methoxyl groups and four hydroxyl groups were shown to be present. Two of the hydroxyl groups could be methylated with diazomethane. The third lignin fraction was found to have a higher percentage of carbon than either of the other two lignin fractions. The percentage of methoxyl did not differ from that of the other two fractions. The alkoxyl groups present in all the three lignin fractions were proved definitely to be methoxyls. All the three fractions when distilled with 12 percent hydrochloric acid afforded some formaldehyde. The lignin fractions isolated from oat straw are closely related to the corresponding lignin fractions isolated from barley straw."

Chemical nature of the vitamins. W. C. RUSSELL (*Sigma Xi Quart.*, 24 (1936) No. 1, pp. 6-8).—This contribution from the New Jersey Experiment Stations consists of a brief review of the literature dealing with the establishment of the chemical nature of vitamins, C, B₁, A, and D. Graphic structural formulas of these and of lactoflavine are presented.

Evidence concerning two types of plant diastase. G. L. TELLER (*Jour. Biol. Chem.*, 114 (1936), No. 2, pp. 425-430, figs. 3).—Germinating barley, rye, and wheat, and certain other plant products are shown to contain two types of sugar-forming diastase. These have different activities in starch media of different pH and at different temperatures. Where both diastases are present the amount of maltose produced at any one point as located by pH and temperature is a resultant of the combined action of the two. The divergence between the results of the two diastases acting in media of different pH is much greater at the higher temperatures of diastatic activities than at the lower.

"At 60° [C.] the difference is such that when the maltose produced by the one diastase in an acid starch paste of pH near 4.5 is divided by the maltose produced in equal time in less acid starch paste, pH near 6.2, the ratio will be materially greater than 1. This is the type characteristic of normal wheat flour and some other but not all reserve substances. It is here called reserve diastase. With the other diastase acting under like conditions, the ratio will be materially less than 1. This is the type developed during germination. It predominates in the bran of germinating cereals and in general in those plant parts most closely associated with active vegetation. It is here called vegetative diastase."

The selective adsorption of enzymes by cellulose. H. TAUBER (*Jour. Biol. Chem.*, 113 (1936), No. 3, pp. 753-757).—The author reports experiments from which he concludes that "cotton exerts selective adsorption toward enzymes.

Its practical application is obvious, since no contamination of the enzyme material occurs, such as takes place with other adsorbents (inorganic gels, tannin, etc.). The use of cotton for filtration of enzyme solutions is therefore impractical, since much of the active enzyme is adsorbed. Cotton should not be used for the filtration of gastric or intestinal juices if enzyme activity is to be determined. If a centrifuge is not available, glass wool or open texture 'fact' filter paper should be used.

"Adsorption by cotton may prove useful in the selective concentration of enzymes and in testing the purity of crystalline enzymes."

The recovery of hydrocyanic acid from fumigated citrus leaves, E. T. BARTHOLOMEW and E. C. RABY (*Jour. Biol. Chem.*, 113 (1936), No. 3, pp. 655-660).—At the California Citrus Experiment Station a photoelectric turbidimeter, specially devised and constructed for the purpose, proved to be very satisfactory for determining hydrocyanic acid in solutions.

"Evidence is presented which indicates that at least a portion of the HCN which enters the living citrus leaves during fumigation is quite rapidly and permanently fixed. Hydrocyanic acid could not be recovered from fumigated citrus leaves by the acid distillation method because it combined with some substance or substances in the distillate. Much more HCN than the leaves would be expected to absorb during the fumigation period had to be added before any could be detected in the distillate. The evidence is not yet complete, but it does not appear that the aldehydes, sugars, or citral were entirely responsible for the disappearance of such large quantities of HCN."

The physiology of *Rhizopus oryzae*, L. B. LOCKWOOD, G. E. WARD, and O. E. MAY (*Jour. Agr. Res. [U. S.]*, 53 (1936), No. 11, pp. 849-857).—The authors of this contribution from the U. S. D. A. Bureau of Chemistry and Soils investigated the physiology of the organism in question primarily from the point of view of its capacity to produce *d*-lactic and fumaric acids.

Though a temperature of 40° C. was more favorable for growth and glucose consumption than was that of 30°, the higher temperature was less favorable for *d*-lactic acid production. "The period of greatest activity in *d*-lactic acid production immediately preceded sporulation. The glucose concentration most favorable for the production of *d*-lactic acid was approximately 15 percent. Slightly greater yields of *d*-lactic acid were obtained when the KH_2PO_4 concentration was 0.6 or 1.2 g per liter than when the concentrations were lower.

"Fumaric acid production was suppressed in cultures containing more than 6 g of NH_4NO_3 per liter. A wide range of NH_4NO_3 concentration, 1.5 to 6 g per liter, was favorable for *d*-lactic acid production.

"*R. oryzae* readily utilized NH_4NO_3 , $(\text{NH}_4)_2\text{SO}_4$, NH_4Cl , urea, *d*-, *L*-alanine, *d*-glutamic acid, glycine, and peptone as nitrogen sources. NaNO_3 was an unsatisfactory nitrogen source, and when NaNO_3 was supplied as the sole source of nitrogen no growth occurred. In the presence of CaCO_3 , ZnSO_4 exerted an influence on the metabolism of *R. oryzae*, the greatest quantity of *d*-lactic acid being produced at the concentration of 10 mg per liter of zinc. Under favorable conditions of nitrogen metabolism, the formation of fumaric acid depended on the maturity of the mycelium."

Semi-micro-Cottrell boiling point apparatus, M. L. WILLARD and D. E. CHARTREE (*Indus. and Engin. Chem., Analyt. Ed.*, 8 (1936), No. 1, pp. 79, 80, fig. 1).—An apparatus of the type named—the principle being that of the bubbling of the liquid and its vapor in equilibrium over either a thermometer bulb or a thermocouple—was redesigned at the Pennsylvania State College for construction in a size about one-tenth of that ordinarily used, and this smaller form of the apparatus was shown to give satisfactory results.

"With an apparatus of 5-cc capacity boiling points were found which were accurate to 0.1° C. The mean deviation for the liquids tried was 0.02°. Starting with 5 cc of pure material, a take-off of 60 percent may be made without causing any variation in the millivolt reading obtained."

A new electrophoresis cell for microscopic observations, M. E. SMITH and M. W. LISSE (*Jour. Phys. Chem.*, 40 (1936), No. 3, pp. 399-412, fig. 1; *abs. in Pennsylvania Sta. Bul.* 336 (1936), p. 15).—A new type of cell (double tube) is described, and its theory and theoretical advantages are discussed, together with the results of an experimental comparison with the usual type of cell. Values of electrophoretic mobilities of finely ground quartz particles in triply distilled water obtained in the new double-tube cell agreed within the experimental error with values as determined in a single cylindrical tube. In both cases observations were made at depths where, theoretically, there should be no movement of the liquid. The consistency of the results secured with the new cell indicated a part of its advantages.

The development of quantitative spectrographic methods for agricultural research, L. W. GADDUM, R. C. WILLIAMSON, and L. H. ROGERS (*Florida Sta. Rpt.* 1936, pp. 97, 98).—Methods for the determination of copper and zinc are noted.

Copper catalysis of the oxidation of thiol acids as a basis for the micro-determination of copper, J. BJERRUM (*Jour. Biol. Chem.*, 114 (1936), No. 2, pp. 357-359).—Comparing the oxidation of cysteine, in the presence of minute quantities of copper, with that of other thiol acids, the author has shown that "thiol acids such as thioglycolic, thiolactic, and thiomaleic acids (contrary to cysteine) were oxidized by air in 0.1 to 1 N hydrochloric acid solution in the presence of traces of copper. The oxidation of both thioglycolic and thiolactic acids to the disulfide acids could be followed by a simple iodine titration, but thiomaleic acid, like cysteine, was oxidized beyond the disulfide stage." The author studied this reaction with a view to the determination of minute quantities of copper compounds and was able to elaborate "a simple iodometric method for the estimation of small amounts of copper of the order of 10⁻⁴ mg. The method requires neither special apparatus nor the use of the more expensive cysteine." The results obtained are shown to agree well with those given by methods involving cysteine oxidation.

A study of the several Minnesota reagents for the determination of fat in buttermilk, E. W. BIRD and D. F. BREAZEALE (*Jour. Dairy Sci.*, 20 (1937), No. 1, pp. 1-7, fig. 1).—Tests conducted at the Iowa Experiment Station showed that different values for the fat content of a single sample of buttermilk were obtained with each of the three Minnesota reagents that have been proposed. The average of 12 tests on a single sample of buttermilk with each of the Minnesota reagents designated as A, B, and C (sold commercially), the American Association, the Babcock, and the Mojonnier methods were 0.512, 0.465, 0.198, 0.739, 0.233, and 0.745 percent, respectively.

Saponification occurred with all three Minnesota reagents during the digestion period, the estimated amounts being 5.17, 8.62, and 16.73 percent for reagents A, B, and C, respectively. Approximately 30 percent of the difference between the readings obtained with reagents A and C was due to saponification, the other 70 percent being ascribed to differences in manipulative procedure.

Rapid determination of oil content and oil quality in flaxseed, L. ZIMMERLY and D. A. COLEMAN (*U. S. Dept. Agr., Tech. Bul.* 554 (1937), pp. 40, figs. 9).—Finding available methods for the determination of the oil content of flaxseed and of the quality of the oil to be too slow for commercial inspection work,

the authors have developed and tested more rapid methods of considerable accuracy.

Following a study of the principal sources of error in the ether-extraction method, "an extraction procedure has been developed which eliminates these errors to a large degree and which serves as a standard check method for use in the development of more rapid methods. A centrifugal method for the rapid determination of oil content has commercial possibilities under conditions where an accuracy of ± 1 -percent oil is sufficient. The method is very simple in operation and requires relatively simple equipment. Approximately eight determinations may be made in an hour, by one analyst. The method is not recommended when a high degree of accuracy is required."

The refractometric method originally proposed by Coleman and Fellows (E. S. R., 57, p. 505) has been perfected to eliminate its chief source of error and so simplified that "the average analyst may quickly master the technic. A high degree of accuracy may be attained by the modified method, as evidenced by the fact that in the analysis of 84 samples of flaxseed, covering a wide variety of types, by both the refractometric method and the petroleum-ether extraction method, a correlation coefficient of $+0.993$ was obtained with a standard error of prediction of ± 0.26 percent of oil for the modified refractometric method. Results obtained by collaborative study show a greater degree of accuracy and reliability for the modified refractometric method than for the standard petroleum-ether extraction method. A single analysis by the modified refractometric method can be made in about 30 min., as compared with the 16 to 24 hr. generally required for the extraction method. Approximately 100 analyses may be made in an 8-hr. day with a single set of equipment by one analyst with the aid of two nontechnical assistants.

"The refractive index of flaxseed oil prepared by special methods may be used as a direct measure of iodine number, the latter value being now used commercially as an approximate measure of the drying quality of the oil. In the analysis of oils from 96 samples of flaxseed, with iodine numbers (Wijs) ranging from 155 to 197, a correlation coefficient of $+0.9965$ between iodine number and refractive index was found, with a standard error of prediction of iodine number of ± 0.82 . When the oil content has been determined by the proposed refractometric method, no additional labor is involved in determining the iodine number refractometrically."

A potentiometric adaptation of the Shaffer-Hartmann sugar method, L. F. NEX and E. S. WEST (*Jour. Biol. Chem.*, 114 (1936), No. 2, pp. 547-550).—This potentiometric adaptation of this method (E. S. R., 45, p. 111) has been found applicable to pure sugar solutions, iron and zinc filtrates of blood, and ferric sulfate-Lloyd's reagent filtrates of urine.

Prevention of foaming in crude-fiber determinations, H. W. GEBRITZ (*Indus. and Engin. Chem., Analyt. Ed.*, 8 (1936), No. 1, p. 75, fig. 1).—"The custom of breaking the foam by blowing through an auxiliary tube or through the condenser requires the constant attention of the analyst. The author has found that a fine jet of air projected on the center of the boiling liquid is as effective in dispersing the foam as a larger current of air. Furthermore, if proper precautions are taken, a fine jet of air may be projected on the surface of the digesting material throughout the digestion period without increasing evaporation." The author's apparatus, devised at the Washington Experiment Station, consisted of capillary jets inserted through the condenser tubes into each flask of a battery of six, all of the jets being connected through a common supply tube to a source of compressed air.

A modified method for the study of tissue oxidations, V. R. POTTER and C. A. ELVEHJEM (*Jour. Biol. Chem.*, 114 (1936), No. 2, pp. 495-504, figs. 3).—The authors of this contribution from the Wisconsin Experiment Station describe a new method for the study of tissue respiration in which the tissues are homogenized in a buffer medium by a high speed glass pestle and studied at various dilutions by means of the Barcroft respirometer. The "dilution effect" (the lowering of the oxygen quotient) which occurs when tissue suspensions are diluted is shown in the base of rat liver and brain and chick liver and kidney; the applicability of the method to the study of succinoxidase is shown; and the possibility of studying other oxidizing systems by adding appropriate coenzymes to tissue suspensions is discussed.

The determination of total base in blood and other biological fluids by the electro dialysis method of Adair and Keys, A. KEYS (*Jour. Biol. Chem.*, 114 (1936), No. 2, pp. 449-459, figs. 3).—The essential feature of this method¹ is that base ions are electro dialyzed from the solution being analyzed across a collodion or cellophane membrane to negatively charged mercury above which stands a known amount of standard acid. When the dialysis is complete, the circuit is broken, the base-mercury amalgam is decomposed by shaking with the acid, and the excess acid is titrated without removing it from the vessel.

As adapted for the purpose here dealt with, the method "gives results accurate to within 1 percent when samples of 0.2 cc of biological fluids are used. By this method at least twenty-four determinations may be made within the course of the day."

Determination of chlorides in biological fluids by the use of adsorption indicators: The use of diphenylamine blue for the volumetric microdetermination of chlorides in urine and blood filtrates, A. SAIFER and M. KORNBLUM (*Jour. Biol. Chem.*, 114 (1936), No. 2, pp. 551-555).—The authors describe a rapid, accurate method for the determination of chlorides in blood filtrates and urine by direct titration with silver nitrate, in which diphenylamine blue is used as an adsorption indicator. "Quantities in the range of 1 mg of sodium chloride can be determined with a maximum deviation of 2 percent."

A study of the estimation of sodium in blood serum, E. G. BALL and J. F. SADUSK, JR. (*Jour. Biol. Chem.*, 113 (1936), No. 3, pp. 661-674).—The authors have devised, at The Johns Hopkins University, a volumetric procedure for the determination of sodium in as little as 0.2 ml of serum. The method is based on the precipitation of sodium as uranyl zinc sodium acetate, the reduction of the uranium in the precipitate to the quadrivalent state, and its subsequent quantitative oxidation with dichromate to the hexavalent condition.

"Serum ash or filtrate may be employed, though results with the latter give values 1 to 3 percent too high, an effect ascribed to a volume displacement by the precipitated protein. Results on ashed samples agreed within 1 percent with those found by the macrochloroplatinate procedure. The gravimetric uranium and pyroantimonate methods were also employed for the sake of comparison and found to be entirely reliable."

The ionization constants of calcium proteinate determined by the solubility of calcium carbonate, E. G. WEIR and A. B. HASTINGS (*Jour. Biol. Chem.*, 114 (1936), No. 2, pp. 397-406).—Determinations of the solubility of calcium carbonate in solutions of casein, serum albumin, and serum globulin were made at 38° C. for several pH values and protein concentrations. From these data, the ionization constants of the calcium salts of these proteins were calculated.

¹ *Jour. Physiol.*, 81 (1934) No. 2, pp. 162-166, fig. 1.

They were found to have the following values: Casein, $pK_{CaProt}=2.23$; globulin, $pK_{CaProt}=2.32$; albumin, $pK_{CaProt}=2.20$. The experimental methods used and the bases of the calculations made are detailed.

Some applications of a new color reaction for creatinine, S. R. BENEDICT and J. A. BEHRE (*Jour. Biol. Chem.*, 114 (1936), No. 2, pp. 515-532, figs. 2).—A new color reaction for creatinine with 3,5-dinitrobenzoic acid in presence of alkali is described. Results obtained by the application of this reaction to various creatinine derivatives, to glycocyamine and hydantoin, and to urine and blood filtrates are recorded. A method for the determination of urinary creatinine by the new reagent is detailed.

"Determinations made upon human urine samples from which creatinine has been removed by Lloyd's reagent indicate that figures for urinary creatinine by the picrate methods are from 2.5 to 5 percent too high. Human blood filtrates yield with the dinitrobenzoic acid method a color so different, both in shade and stability, from that given by creatinine that the chromogenic substance in such filtrates cannot be determined as creatinine." The significance of these results in relation to the question of the creatinine chromogenic material of blood is discussed, the findings being interpreted as furnishing further evidence in favor of the view that this chromogenic material is not creatinine.

An examination of the Sullivan colorimetric test for guanidine, C. E. BRAUN and F. M. REES (*Jour. Biol. Chem.*, 114 (1936), No. 2, pp. 415-417).—The authors of this contribution from the University of Vermont, having available a number of new mono- and diguanidine derivatives, subjected the specificity of the test named to a critical study. They find that in view of the "observations made on 36 different guanidine derivatives, not including various salts of the same base, it must be concluded that the Sullivan colorimetric test for the detection of free guanidine is not as highly specific as was first thought, since the reaction is positive with certain substituted guanidines. However, in consideration of the fact that the interfering guanidine structures mentioned above normally would not be expected to be found in biological fluids, the specificity and value of the Sullivan test in clinical investigations still remain."

Ascorbic acid oxidase in determining vitamin C in lens and aqueous humor, L. ROSNER and J. BELLows (*Soc. Exptl. Biol. and Med. Proc.*, 34 (1936), No. 4, pp. 493, 494).—The vitamin C content of the lens was determined by two extractions with 5 percent metaphosphoric acid, centrifuged, washed, and made up to a volume of 50 cc. A 1-cc aliquot was treated with 2,6-dichlorophenolindophenol, and another 1-cc aliquot was incubated for 30 min. at pH 5.5 with 1 cc of enzyme extract. The solution was brought to pH 2 with sulfuric acid and titrated. Similar experiments were made upon the aqueous humor. The results indicate that at pH 2 the total reducing action of the lens and aqueous humor on Tillman's reagent is due to the vitamin C content.

AGRICULTURAL METEOROLOGY

Monthly Weather Review, [November-December 1936] (*U. S. Mo. Weather Rev.*, 64 (1936), Nos. 11, pp. 351-395, pls. 10, figs. 24; 12, pp. 397-448, pls. 12, figs. 28).—In addition to the usual detailed summaries of climatological data, solar and aerological observations, observations on weather on the Atlantic and Pacific Oceans and on rivers and floods, and bibliographical and other information, these numbers contain the following contributions:

No. 11.—Structure and Maintenance of Dry-Type Moisture Discontinuities Not Developed by Subsidence, by J. Namias (pp. 351-358); Long-Period Weather Changes and Methods of Forecasting, by H. H. Clayton (pp. 359-376) (see

p. 12); Corrections to Atmospheric Turbidity and Water Vapor Values as Computed from Solar Radiation Intensity Measurements at the Blue Hill Meteorological Observatory of Harvard University During 1936, by H. H. Kimball (p. 377); and Notes and Reviews: Introduction to the Study of Air Mass Analysis, by J. Namias (pp. 377, 378).

No. 12.—Energy of Conditional Instability, by W. Littwin (pp. 397–400); Synoptic Determination and Forecasting Significance of Cold Fronts Aloft, by B. Holzman (pp. 400–414); Upper-Air Cold Fronts in North America, by S. Lichtblau (pp. 414–425); Preliminary Report on Tornadoes in the United States During 1936, by J. P. Kohler (pp. 426, 427); Tropical Disturbances of 1936, by I. R. Tannehill (pp. 427, 428); Extratropical Disturbances in Low Latitudes of Mid-Atlantic, December 1936, by J. H. Gallenne (p. 428); Duststorms of August–December 1936 in the United States, by R. J. Martin (p. 429); and On the Computation of Atmospheric Turbidity and Water Vapor from Solar Radiation Measurements—A Correction to Previous Note, by H. H. Kimball (p. 430).

Measurement of precipitation, B. C. KADEL (*U. S. Dept. Agr., Weather Bur. Circ. B, 4, ed., rev. (1936), pp. [1] + 25, figs. 13*).—The instructions given (E. S. R., 47, p. 810) are revised to 1936.

The human side of snow, J. E. CHURCH (*Sci. Mo., 44 (1937), No. 2, pp. 157–149, figs. 16*).—This article tells the story of the Mount Rose observatory overlooking Lake Tahoe, Nev., at an elevation of 10,800 ft., and of the development of a world-wide system of snow measurement as a basis for forecasting water supply from this source for irrigation, power, and other useful purposes. It shows how, "in the space of less than half a century, a trip made solely in love of winter nature has given birth to snow surveying and to a world organization whose central purpose is to study the scientific and human aspects of snow and ice, now designated as a new field in hydrology and by some as a new science with the forbidding name of cryology (the science of cold)." The basic study has been a research project of the Nevada Experiment Station for many years.

Conference on atmospheric ozone held at Oxford, September 9th to 11th, 1936 (*Quart. Jour. Roy. Met. Soc. [London], 62 (1936), Sup., pp. IV + 76, figs. 14*).—Papers presented and discussed at this conference dealt with methods of measurement of ozone, vertical distribution of ozone, absorption of radiation and temperature of the upper atmosphere, horizontal distribution of ozone and weather conditions, and miscellaneous subjects.

A paper on Variations in Atmospheric Ozone and Weather Conditions, by G. M. B. Dobson (pp. 52–54) states that "one of the most interesting results that has come out of the study of the amount of ozone in the atmosphere is the relation which is found between the amount of ozone and the weather conditions", but that unfortunately little progress has recently been made in the study of this subject. "At the present time we know that large changes in the amount of ozone may take place within a few days—changes of the order of ± 25 percent—and these changes are closely associated with changes in the weather conditions. Around a cyclonic depression the amount of ozone is nearly everywhere above the average, and it is particularly high just to the west of the center of low pressure. . . . It is also of great interest to find that the ozone content of the atmosphere is very closely related to several meteorological characteristics of the upper atmosphere. . . . The possible aid which ozone observations might give to weather forecasting makes it very desirable that the subject should be thoroughly explored."

Is our climate changing? J. B. KINCEE (*Sci. Digest, 1 (1937), No. 1, pp. 39–41*).—From a study of the evidence for and against significant changes in

climate, with particular reference to droughts, the author concludes that "our longest records indicate that there has been no permanent change in climate, but rather we are going through a dry phase of our normal climate, of which the present family of droughts is a part."

Long-period weather changes and methods of forecasting, H. H. CLAYTON (*U. S. Mo. Weather Rev.*, 64 (1936), No. 11, pp. 359-376, figs. 21).—The development of the author's system of long-period forecasting, based upon his belief that variations in weekly, monthly, or annual means of pressure are "the results of large atmospheric movements of orderly procedure, and hence predictable when understood," is explained. The essentials of the system are briefly stated as follows: "(1) The analysis of weather phenomena into pulses, waves, or periods of different length; this is done for each station in a network of stations, and the latest values plotted on maps. From a succession of such maps the movements of areas of excess and deficiency can be followed and their future position anticipated; (2) correlation of the meteorological pulses or waves with solar radiation pulses or waves found in the same way; (3) projection of these waves ahead into the future, using for this purpose the mean lengths of the solar periods determined by experience or calculation; (4) reading from each of the curves so projected ahead the value for some particular time or epoch desired, and summing the different values thus obtained; (5) the process described in (3) is done for a network of stations, the sums are plotted on maps and lines of equal value drawn. These maps then become a forecast for the area covered."

Methods of seasonal weather forecasting in California, G. F. McEWEN (*Citrus Leaves*, 17 (1936), No. 12, pp. 22, 26).—It is stated that "evidence is accumulating in support of a correlation between the general trend of sea temperatures and atmospheric temperatures and between each of these and the general trend of precipitation in this Pacific coastal region. In particular, the gradient between winter and late fall sea surface temperatures appears to be an important advance index of precipitation." Using such correlations the Scripps Institution of Oceanography, in June 1936, issued the following predictions of air temperature trends in southern California, which it is stated have been well verified to date: "San Diego, 1° above from June to September; Santa Ana, about average from June to September; Riverside, irregularly 1° to 3° above from June to September, greatest excess in August."

[Meteorological and crop protection service], **E. S. ELLISON** (*Florida Sta. Rpt. 1936*, pp. [4], 99-106, 115-117, 142, figs. 4).—This includes the first year's report of work of the activities of the Federal-State Horticultural Protection Service in Florida, which was established in cooperation with the station and the U. S. Weather Bureau with a Federal appropriation of \$15,000 and a State appropriation of \$10,000 annually, primarily to reduce losses caused by frost and freezes. The essential features are a temperature survey based on observing stations well distributed throughout the State and a forecast and frost warning service. Some cooperative experiments in frost protection for tomatoes, peppers, and eggplants in areas where these are major crops are reported. The station continued its usual observations in the Everglades and at Quincy on temperature, rainfall, and evaporation, and studied the relation of wind velocity to barometric pressure.

SOILS—FERTILIZERS

[Soil and fertilizer studies by the Florida Station] (*Florida Sta. Rpt. 1936*, pp. 59, 60, 61, 124, 125, 127, 128, 137, 138).—Notes are given on the determination of the effect of green manures on the composition of the soil and the occurrence

and behavior of zinc in soils, both by R. M. Barnette; saline soil studies, oxidation of sawgrass peat as related to its conservation, physical changes in peat and muck, green manure experiments, nitrate accumulation, soil reaction, and studies upon the role of zinc and other special elements in plant development upon the peat and muck soils of the Everglades, all by J. R. Neller and R. E. Robertson; and on root environment in sawgrass peat, nature of subsurface waters, and the need for phosphorus, by Neller.

[Soil investigations of the Oklahoma Station] (*Oklahoma Sta. [Bien.] Rpt. 1935-36, pp. 98-103, figs. 2*).—The report contains brief discussions on the soil survey as the basis of economic land use, importance of lime in Oklahoma, and cropping systems for the maintenance of the organic matter and nitrogen content of Oklahoma soils, all by H. J. Harper.

[Soil and fertilizer investigations of the Pennsylvania Station] (*Pennsylvania Sta. Bul. 336 (1936), pp. 21, 22, 23*).—Notes are presented on the relative value of limestone of various degrees of fineness, by J. W. White and F. J. Holben; and on lime and fertilizer for Volusia soils, by White, Holben, and Jeffries.

[Soil and fertilizer investigations of the Utah Station] (*Utah Sta. Bul. 276 (1936), pp. 35-45, figs. 7*).—This station summarizes recent work under the following captions: Fine-textured soils of the Delta area make diversified farming difficult, soil surveys of the State are resumed, and study made of soil productivity in regard to land and water use, all by D. S. Jennings; what is responsible for loss of nitrogen and organic matter in dry-land soils, by J. E. Greaves and A. F. Bracken; determine friability of soils, by Jennings et al.; strawberry clover shows promise for western alkali lands, by R. J. Evans and D. W. Pittman; what is the proper treatment of alkali land, summarize results of cropping and manuring systems on soil productivity, and statewide commercial fertilizer tests show interesting results, all by Pittman; trials at Sanpete County Farm indicate best practices for peat soils, by L. Wilson; Carbon County soils subject to erosion, by I. D. Zobell; commercial fertilizers prove highly beneficial in irrigated pasture studies, by G. Q. Bateman, Evans, and Pittman; benefits of commercial fertilizers to soil fertility summarized, by Greaves, Jennings, and Pittman; orchard soils analyzed for arsenic content and alfalfa changes nitrogen-fixing properties of soil, both by Greaves and K. R. Stevens; and Greenville Farm soil has abundance of nitrogen, by Greaves and C. T. Hirst.

Soils of Teton County: Soil reconnaissance of Montana—Preliminary report, L. F. GIESEKER (*Montana Sta. Bul. 332 (1937), pp. 63, fig. 1, maps 4*).—Teton County covers an area of 2,205 sq. miles in northwestern Montana. Its present boundaries enclose a fairly compact agricultural area, in which some of the more important dry and irrigated lands in the State are located. The present preliminary survey indicated 21 series of 41 types, the area mapped as Bainville loams, 10.1 percent of the total area of the county, being the largest area designated as of a single type. Mountains occupy 19.7 percent.

Soil survey of Broome County, New York, C. LOUNSBURY ET AL. (*U. S. Dept. Agr., Bur. Chem. and Soils [Soil Survey Rpt.], Ser. 1932, No. 11, pp. 40, pls. 2, figs. 2, map 1*).—Broome County occupies 451,200 acres of a plateau dissected by natural drainageways in the southern part of New York State. The topography of the county is characterized by "well-rounded valley slopes and rather narrow ridge tops, the result of the action of glaciers."

According to this survey, made in cooperation with the [New York] Cornell Experiment Station, the Canfield and Lordstown gravelly silt loams and Volusia silt loam are among the more extensively developed soils, constituting,

respectively, 20.9, 10.5, and 19.2 percent of the area surveyed. There were found altogether 10 soil series, inclusive of 28 types. These types are classified according to their productivity for various crops.

Soils of Collin, Frio, Galveston, Midland, Potter, and Van Zandt Counties and the Trans-Pecos area, G. S. FRAPS and J. F. FUDGE (*Texas Sta. Bul. 533* (1936), pp. 54).—Supplementing U. S. D. A. Soil Surveys (E. S. R., 70, pp. 158, 448; 71, p. 750; 73 p. 14; 74, p. 10), chemical analyses and results of pot experiments on samples of typical soils from six counties and the Trans-Pecos region are presented, together with condensed descriptions of the soil series. A new classification of constituents, five classes based upon chemical composition, is proposed, and its relation to previous methods of interpretation is discussed.

"Most of the soils are low (classes 4 and 5) in nitrogen and phosphoric acid. They are better supplied (classes 2 and 3) with potash. Some of the soils are low in lime and basicity (classes 4 and 5), while others are basic and even highly calcareous (class 1). Some of the soils are slightly acid, but most of them are neutral to alkaline."

Peat land in the Pacific Coast States in relation to land and water resources, A. P. DACHNOWSKI-STOKES (*U. S. Dept. Agr., Misc. Pub. 248* (1936), pp. 68, pls. 3, figs. 3).—A study has been made of various peat areas in California, Oregon, Washington, and northern Idaho. Information is given in detail concerning the genesis and intrinsic physical characteristics of peat profiles, the relation of their composition to the present cover of vegetation and to historical ecologic antecedents, the modifying conditions that determine the development of organic soils and their general productivity for crops, the uses of peat resources in connection with the commercial production of peat and muck as organic matter for soil improvement, and the conservation of surface waters and ground-water supplies.

"From the information at hand it appears that heavy losses and deterioration of peat land have been caused in recent years, notably in the Klamath Basin and in the southern Pacific section, by excessive drainage, the spreading injury by 'alkali' and salt accumulation, damage from fires, wind erosion, and reclamation of peat land of doubtful agricultural value.

"To forestall a critical water shortage in the coastal States and to increase water supplies, the restoration of water levels and original cover of vegetation or an approximation to it would prove an invaluable step. . . . To bring more peat land under cultivation appears to be undesirable under present economic and critical ground-water conditions. These hazards in the West must bring some consideration of the necessity of withdrawing areas of peat land from unsuitable agricultural and industrial uses, and allowing them to produce a type of native vegetation that would offer a barrier to floodwaters and silting, absorb rainfall, impound water supplies, and increase the water content of the ground by percolation."

Trace elements in the soils from the erosion experiment stations, with supplementary data on other soils, C. S. SLATER, R. S. HOLMES, and H. G. BYRNS (*U. S. Dept. Agr., Tech. Bul. 532* (1937), pp. 24).—Analytical methods have been adapted to the determination of certain elements when present in soils in quantities which are best expressed in parts per million. Data to show the degree of accuracy of the results obtained are given. Eleven profiles of soil types from 10 of the erosion experiment station soils, representing 4 of the great soil groups, were examined, together with 3 other soil types.

"Selenium, arsenic, copper, cobalt, nickel, zinc, and vanadium were found in varying quantities in all the soils examined for them. Barium was found in all the soils except one sample derived from the Niobrara shale very rich in

calcium carbonate. Molybdenum was found only in the Pierre and Niobrara samples. The limiting quantities found were: Selenium, 0.01 to 22 p. p. m.; arsenic, 1 to 83 p. p. m.; copper, 1 to 44.6 p. p. m.; cobalt, 0 to 2.4 p. p. m.; nickel, 0.5 to 22.5 p. p. m.; zinc, 3 to 147 p. p. m.; barium, 0 to 2,123 p. p. m.; chromium, 0 to 93 p. p. m.; vanadium, from 5 to 430 p. p. m.; and molybdenum, 0 to 6 p. p. m. In the 11 erosion experiment station soils no evidence was secured indicating the presence of germanium, tin, gold, cadmium, tellurium, or the platinum metals.

"The distribution of trace elements found is shown to be very extensive, and their total absence from any soil is improbable. No attempt has been made to determine the effect of their presence on either the quality or quantity of vegetation [or] to show whether the quantities shown to be present are adequate or represent soil deficiencies. . . .

"The distribution of the trace elements within soil profiles shows the general relationships which are to be expected from the operation of the soil-forming processes. It seems clear that the primary sources of these elements are in the parent materials, and that soil-forming processes have not in most cases extensively modified the quantities present. Some eluviation is indicated by the distribution of vanadium and selenium, particularly in the soils which contain much iron oxide."

Some physico-chemical relationships found in four erosive soils of the Piedmont Plateau region, H. T. ROGERS (*Jour. Amer. Soc. Agron.*, 29 (1937), No. 1, pp. 1-9, fig. 1).—Noting that "the clay pan nature of the B horizon of the Iredell, White Store, Helena, and Orange soils of the Piedmont Plateau region, linked with their apparent susceptibility to severe erosion, suggested a comparative study of their profiles", the author of this contribution from the Michigan Experiment Station reports such a study and finds that "an analysis of the data obtained . . . reveals some significant relationships between certain physical and chemical properties.

"A correlation coefficient of 0.923 ± 0.358 was found when hygroscopic water content was correlated with cation exchange capacity. These two properties are more closely related than percentage colloid and cation exchange capacity (correlation coefficient 0.752 ± 0.1053). This indicates that the ability of soil colloids to hold water against evaporation forces is an accurate measure of their ability to adsorb cations in ionic exchange. A high negative correlation (-0.712 ± 0.1196) existed between H-ion concentration and percentage base saturation. The data obtained show that there is very little relationship between H-ion concentration and total exchangeable hydrogen in soils with widely different cation exchange capacities. High correlation coefficients obtained for both hygroscopic water and maximum water-holding capacity and hygroscopic water and moisture equivalent show that any one of these values may be calculated from either of the others by means of a constant, with a high degree of accuracy."

Apparatus for the measurement of shrinkage coefficient of soils, B. N. SINGH and P. B. MATHUR (*Soil Sci.*, 43 (1937), No. 1, pp. 37-41, fig. 1).—"The principle of the apparatus consists in finding the volume of the gas space in a soil chamber with and without a soil ball and determining the volume of the soil ball by subtracting the one from the other. The volume of the gas space in the soil chamber is determined in the following manner: A portion of gas is withdrawn from the soil chamber, and its volume is determined at the atmospheric pressure. The lowering of pressure in the soil chamber following the withdrawal of the gas is also noted. By applying the Boyle-Mariotte law, the volume of the gas space in the soil chamber is easily computed from these data."

A new method for determining the porosity of the soil, G. TORSTENSSON and S. ERIKSSON (*Soil Sci.*, 42 (1936), No. 6, pp. 405-417, pl. 1, fig. 1).—In a contribution from the Agriculture College of Sweden, the authors describe a "porosimeter" by means of which the air space in a soil sample may be determined by an application of Boyle's law. The sample is placed in a closed space of accurately known volume, and the change in the volume of the total air content of the apparatus corresponding to a known change (effected by an adjustment of a column of mercury in a graduated tube) in the pressure upon the contained air provides the data necessary for the calculation of the air space in the soil sample.

The authors also point out the possibility of determining the specific gravity of a dry soil sample and of determining the water content of a soil of known specific gravity.

A lettered diagram shows the nature and function of each detail of the apparatus, which is also shown as a whole in a photograph. The simple calculation involved is illustrated by a literal solution.

Accuracy of a soil thermograph, G. A. MARR (*Soil Sci.*, 43 (1937), No. 1, pp. 27-30, fig. 1).—By means of temperature gradients and related conditions artificially controlled in a small body of soil in the laboratory so arranged as to magnify somewhat the sources of error met with in measurements of soil temperatures under natural conditions, the author of this contribution from the Montana Experiment Station has brought out certain limitations of the accuracy of corresponding field measurements.

"That the conditions described are most extreme and not likely to be encountered under normal conditions is granted, yet it is indicated that under certain circumstances the readings of a thermograph may not be exact. In the Centennial Valley in Montana, at 7,000 ft. altitude, one of these thermographs records winter soil temperatures at 2 in. Although the air temperatures drop to very low points, at times to -60° F. during the coldest part of the day, there is a snow blanket beneath which the soil surface temperatures will rarely go much below zero. With the bulb buried at so shallow a depth, most of the capillary cable is in the air, and, with the instrument head exposed to -60° , we have, therefore, in this instance an actual case where there is a 60° difference between the instrument and the bulb, and the record may be off as much as 3° from the actual temperature. The temperature gradient in some soils, especially within the surface 4 in., is often very sharp. With a thermograph bulb $1\frac{1}{8}$ in. in diameter buried with its median axis only 2 in. below the soil surface, as it is in grasshopper investigations, the combination of a sharp temperature gradient of some degrees within that space of $1\frac{1}{8}$ in. together with the conduction down the metal cable will result in error. For temperature measurements at greater depths this device ought to be very reliable.

"To overcome the afore-mentioned difficulty it is suggested that for temperature measurements of shallow depths at least 3 ft. of the capillary tubing be buried at the same depth as the bulb, so that the tube will have an opportunity to come to equilibrium with the surrounding temperature before it connects with the bulb."

On the formation of structure in soils.—II, Synthesis of aggregates; on the bonds uniting clay with sand and clay with humus, D. I. SIMMER (*Soil Sci.*, 42 (1936), No. 6, pp. 461-481, pl. 1).—Carrying forward experimental work recently noted (*E. S. R.*, 76, p. 592), the author has found evidence supporting a new theory of structure formation based on the capacity of soil colloids to form phases of the aggregate state.

"The former conception that the particles forming the soil structural aggregate are held together by the tension of the water film is supplemented by the finding that the surface film creates a definite orientation of the particles in relation to one another. The tenacity of the bond between the separate parts of the soil structural aggregate cannot be explained by the presence of absorbed Ca. The explanation of the tenacity of this bond lies in the stability of the group arrangement of the particles. The most stable arrangement of particles is the homogeneous one. The formation of non-homogeneous aggregates in soil—sand clay and clay humus—may be explained by the same laws which have been found to exist for mineral intergrowths. The impossibility of completely separating soil into its elementary parts is corroborated. In connection with the theory developed, it becomes necessary to revise the theory of soil texture. The subdivision of soil into stable and unstable groupings of particles appears to be more expedient. The influence of external conditions (vegetation, micro-organisms, tillage, pressure, freezing, etc.) on the formation of structure can be explained by the swarm theory."

Chemical and physical changes in soil colloids with advancing development in Illinois soils, R. H. BRAY (*Soil Sci.*, 43 (1937), No. 1, pp. 1-14, figs. 2).—The author describes, in a contribution from the Illinois Experiment Station, physical and chemical changes brought about by the five stages of weathering illustrated by the Hartsburg, Grundy, Harrison, Putnam, and Cisne silt loams. The physical study consisted mainly in the determination of the quantity and distribution of the coarse, fine, and extremely fine particle size fractions found in the colloidal material. With reference to chemical changes it was found, in part, that "the general tendency is for the K_2O , MgO , and Fe_2O_3 to decrease with advancing development and for the $\frac{SiO_2}{R_2O_3}$ ratio to increase." A chemical effect of physical weathering was found in the conversion of a mica-type mineral into a beidellite. "The mica loses its potash and part of its magnesium, taking up water in the process, and forms a beidellite-type mineral containing some magnesium and no potash but possessing base-exchange properties. Before physical weathering the beidellite is still attached to the mica. After physical weathering considerable of the beidellite but only a very small part of the mica is broken off, becoming part of the superfine (and fine) fraction. This will increase the K and Mg content of the coarse fraction and decrease its base-exchange capacity, and where quartz is present . . . the relative quartz content will be increased."

Soil conservation from the viewpoint of soil physics, R. BRADFIELD (*Jour. Amer. Soc. Agron.*, 29 (1937), No. 2, pp. 85-92).—This discussion, contributed from the Ohio Experiment Station, brings out the original and the present status, and proceeds to the question "what can we do to insure good physical conditions in our arable soils?" A final section of the paper discusses mainly the beneficial effects of a grass-legume mixture grown for several years. A physical hypothesis to explain the nature of the improvement in the structure of the soil effected by such management is developed. The conclusion is that "the experience of our better farmers throughout the world, the carefully controlled experiments of our older experiment stations, the accumulated experiences of the older agricultural sections of Europe, all indicate that the most feasible way of maintaining soil structure is by combining arable agriculture with grassland farming."

Soil conservation from the viewpoint of soil chemistry, E. E. DETURCK (*Jour. Amer. Soc. Agron.*, 29 (1937), No. 2, pp. 93-112, figs. 4).—This contribu-

tion from the Illinois Experiment Station discusses in detail the natural deterioration of soils as a continuation of the processes involved in soil development. The chemical nature of the cycle is separately considered for the respective cases of potassium, of the soil organic matter, and of phosphorus. "The role of man in soil deterioration" is then similarly taken up under the subheadings colloids and base exchange, organic matter, phosphorus, and other elements. It is pointed out, in conclusion, that "nature and man have contributed in varying degree to the depletion of soils as reflected by their chemical characteristics. Remedial measures can effect restoration in varying degree, according to the nature and extent of the deterioration. What of the highest producing soils? Even though freed as completely as possible of fertility handicaps of the soil itself and located in a favorable climatic environment, average yields are only from one-half to three-fourths as high as the yields which it seems should be expected and which, as on the poor soils, are attained occasionally. This problem is not solved, but a step in advance is being taken. When the capacity of the soil to supply the crop is stepped up beyond the capacity of the crop to utilize it, the time is ripe for the soils men to team up with the workers in crop production and plant breeding in the interests of harmonizing the crop and the soil."

Soil deterioration and soil conservation from the viewpoint of soil microbiology, S. A. WAKSMAN (*Jour. Amer. Soc. Agron.*, 29 (1937), No. 2, pp. 113-122).—The author of the third and final paper of this soil conservation symposium (a contribution from the New Jersey Experiment Stations) finds, with respect to the influence of soil micro-organisms in the development and deterioration of soils, that "the problems of water and wind erosion of the soil, as well as soil deterioration due to improper systems of cultivation, are closely associated with the problem of soil organic matter. A decrease in the organic matter content of the soil accompanies soil deterioration and is in itself a cause for further deterioration of the soil, while an increase of the content of organic matter and nitrogen is a symbol of soil improvement. Micro-organisms are closely associated both with the formation and with the destruction of the organic matter in the soil and with an increase or a decrease of the available nitrogen. Any systems of permanent soil improvement or soil conservation must, therefore, consider the influence of soil treatment upon the activities of the soil-inhabiting micro-organisms, as well as the methods of utilizing their activities in order to bring about a permanent system of agriculture. Furthermore, soil erosion results in the loss of the 'active' or 'living' surface layer of the soil, leaving the 'dead' subsoil. The latter, because of lack of aeration and lack of sufficient nutrients, limits the growth of the important micro-organisms. The soil may also become infested with pathogenic organisms as a result of certain systems of cropping, thus leading to a condition which characterizes 'sick' or 'exhausted' soils. This condition can be prevented or corrected by proper systems of crop rotation and soil improvement. Soil conservation must keep a proper balance of the microbiological population of the soil and a proper state of microbiological efficiency."

Soil conservation reconnaissance survey of the southern Great Plains wind-erosion area, A. H. JOEL (*U. S. Dept. Agr., Tech. Bul. 556* (1937), pp. 68, pls. 14, figs. 2).—The author describes the topography, natural vegetation, agriculture, and agricultural history of the area, dividing the lands surveyed into nine groups of soils "recognized and mapped on the basis of their inherent characteristics as related to their susceptibility to erosion and to agricultural adaptations."

Other findings of the survey are, in part, as follows: "For the area as a whole the erosion situation is serious. A total of 97.6 percent of the entire area has been affected by accelerated erosion of one type or another. A total of 53.4 percent of the area has been affected to a serious degree by accelerated erosion induced by wind or water or both. Soil types of all the soil groups represented, except the stream bottom and terrace lands of group 8, have been seriously affected. Water erosion over the area is not serious, except locally. Only 13.6 percent of the area has been affected by water erosion and only 4.4 percent affected by water erosion to a serious degree. Soils of group 9, which includes most of the steeper slopes, have been affected to the greatest extent. The need for water conservation over the area as a whole is urgent. It is essential for the economic production of crops to improve the ranges and to check wind erosion by increasing vegetative protection both on range and on cultivated lands. Wind erosion is generally serious over the area, in many places alarming. Eighty-three and three-tenths percent of the whole area may be considered affected to a variable degree by wind-erosion damage of one type or another, and 42.5 percent of the area by wind erosion to a serious degree. A total of 91.6 percent of all erosion in the area is by wind. Combined removal and accumulation is by far the most extensive type of wind erosion, 58.2 percent of the whole area having been affected in this manner. . . .

"Some of the more important measures recommended are (1) basic soil-conservation surveys and economic and social surveys of the whole affected area at an early date; (2) the early effective application of an emergency erosion-control and long-time soil-conservation program; (3) general reorganization of land use to include the removal of certain lands from cultivation, the reorganization of such lands into large units for large-scale livestock production, with crop production at economic minimum, revegetation where advisable, and the general adoption of cropping and grazing practices that are suitable to the area and that will conserve moisture and control erosion; and (4) the economic and social adjustments necessary to effect the above recommendations. Education and legislation are necessary to encourage and enforce the necessary cooperation of the many individuals, business interests, and groups involved."

Soil conservation practices, R. EL UHLAND (*U. S. Dept. Agr., Soil Conserv. Serv., 1936, pp. [2]+179, figs. 85*)—The purpose of this handbook is to bring together in concise form some of the latest technical information on erosion control, with special reference to Missouri and Iowa. It contains sections on land inventory and utilization, cropping practices (agronomy), forestry practices, wildlife conservation, and engineering methods.

Conservation farming practices and flood control, H. H. BENNETT (*U. S. Dept. Agr., Misc. Pub. 253 (1936), pp. 16, figs. 15*).—A popular discussion is given of a few of the conservation farming practices found by experience and investigation to be effective in erosion control and which promise substantial aid to upstream flood control and soil protection.

Soil conservation practices in actual use by farmers, Eastern Highland Rim, 1932-1936, C. E. ALLEED and D. H. ESBY (*Tennessee Sta., Agr. Econ. and Rural Sociol. Dept. Monog. 28 (1937), pp. IV+38, figs. 11*).—Approximately 95 percent of the 100 farmers surveyed, in cooperation with the U. S. Department of Agriculture, have done gully control work on their farms, indicating that erosion is a problem on almost all the farms. A list of plants and plans adapted to the area is appended.

Soil moisture conservation, R. B. DRAKE (*Agr. Engin., 18 (1937), No. 1, pp. 15, 16, figs. 2*).—In a brief contribution from the U. S. D. A. Soil Conservation

Service data are presented showing the effect of tillage in storing water in the soil and the amount of moisture used by the wheat crop on continuous wheat and fallow land. Attention is drawn to the possible usefulness of basin lister tillage on fallow land in moisture conservation.

[Soil erosion control investigations by the South Carolina Station], T. C. PEELE, F. MOSER, and C. S. PATRICK (*South Carolina Sta. Rpt. 1936, pp. 19, 21-23, 62-64, figs. 4*).—The progress results are briefly presented of investigations in soil erosion control, including studies of water run-off under various cropping systems and terracing.

Emergency wind-erosion control, G. K. RULE (*U. S. Dept. Agr. Circ. 480 (1937), pp 11, figs. 9*).—This circular suggests two definitely protective measures which are practicable for immediate application in the Great Plains wind-erosion area. The farmer in this region "can protect stalk, stubble, and pasture fields from being overgrazed or burned, and he can have his unprotected fields roughened before the soil starts drifting."

Of the burning or overgrazing of crop residues, it is noted that "some of the worst examples of wind erosion on the Plains may be traced directly to these two destructive practices. . . . If it is absolutely necessary to pasture these fields, it should be done under close supervision. Flocks or herds should be removed before the ground cover is seriously jeopardized."

Of the second measure of protection, the roughening of the soil before the ground freezes in the fall and the re-treatment of leveled or blown spots in the spring before the onset of strong winds, it is pointed out that in general "obstructions of any kind in the path of a moving stream of wind-blown soil will check the driving force of the wind and pile up the soil. . . . Any tillage implement that roughens the surface and leaves it furrowed may be used. More permanent results are obtained if the furrows are deep and if the surface is left in a cloddy condition."

Of various means for securing an effective roughening, the lister is preferred wherever its use is practicable because its deeper furrows provide for more effective trapping of moving soil and of heavy rains. The shovel cultivator, with the two outside shovels set straight and all others removed, is considered "very effective" and cheaper to operate because of its light draft and its rapidity. Its furrows have, however, "little capacity for storing rain water." It is further pointed out that "the chisel cultivator is an effective implement to use if the soil is so dry that clods cannot be brought to the surface with a lister. . . . On land too hard and dry to work with a lister some farmers have had success in using the 'wide-spaced one-way.' This implement is an ordinary one-way disk plow with most of the disks removed. Other types of implements at hand may be used, but the important point to consider is their effectiveness in erecting clod and furrow barriers against the wind so that moving soil may be trapped." Strip listing and the use of the hole digger are also mentioned as useful practices, and "if it is impracticable to run the tillage furrows on the contour because the land is excessively hummocky, or for other reasons, the basin lister may be used. . . . This tool is very effective in conserving moisture. Even though the furrows are run only on an approximate contour, each little dam across the furrow channel traps some water." Contour listing appears the most effective of these measures, however, and one of the illustrations strikingly shows the effectiveness of contour listing in holding the water of a 2-in. rainfall.

Since any form of emergency tillage "must be considered as only a temporary measure", however, "the pressing problem for the future is to find ways of minimizing the hazard of having bare land exposed to the wind. The land

must be given a more adequate cover of native grass, and cultivated crops better adapted to the Great Plains region must be grown."

Early erosion-control practices in Virginia, A. R. HALL (*U. S. Dept. Agr., Misc. Pub. 256 (1937), pp. 31, figs. 4*).—This is a popular historical document, accompanied by a bibliography of 93 references to the literature.

Saving Virginia soils, L. CARRIE ET AL. (*U. S. Dept. Agr., Soil Conserv. Serv., 1936, SCS-1P-16, pp. [1]+23, figs. 5*).—This is a popular treatise on soil conservation by terracing, contour tillage, crop rotation, and erosion and run-off control measures.

Planting of woody plants for erosion control, G. W. HOOD (*U. S. Dept. Agr., Soil Conserv. Serv. Bul. 1, rev. (1936), pp. [1]+38, pl. 1, figs. 16*).—This is an elementary and general discussion of the subject.

Soil fertility studies, N. MCKAIG, JR., and E. M. ROLLER (*South Carolina Sta. Rpt. 1936, pp. 115-119*).—Lysimeter trials of various treatments of Norfolk sands of low organic matter and colloid content and of low productivity are noted.

Experiments reveal soil deficiencies, A. B. BRYAN (*Better Crops with Plant Food, 21 (1936), No. 1, pp. 18-20, 40, 41, figs. 2*).—This is a brief discussion of fertilizer experiments of the usual type, carried out at the South Carolina Sandhill Substation.

The nitrate nitrogen in the soil as influenced by the crop and the soil treatments, W. A. ALBRECHT (*Missouri Sta. Res. Bul. 250 (1937), pp. 27, figs. 20*).—This study discusses the results of determinations of the nitrate nitrogen in the soil of a series of 11 plats of a rolling phase of Shelby silt loam under various crops and cultural variations during 13 yr.

"Such determinations do not measure the amount of nitrates produced or removed but rather the nitrate level at which the production of nitrates is temporarily balanced against their consumption by the plants as the crop above the soil or by the nitrate consuming micro-organisms within it. They measure, however, the lowest level to which the supply in the soil can be, or is, exhausted by the crops or by leaching and the heights to which the accumulation may mount against, or in absence of, these reducing forces. That the crop is a significant factor in removing the nitrates is shown by the lower nitrate accumulation in the cropped soil in contrast to that in the fallowed soil. Without the crop the seasonal nitrate nitrogen levels fluctuated from approximately 21 lb. at the lower level to 42 lb. as the upper figure. For the crops, their exhaustion of the nitrates was very similar whether grass, corn, or wheat. The similarity was greatest between wheat and grass whose average lower levels were . . . 6 lb. and upper levels . . . 12 lb. . . .

"Soil tillage is a beneficial soil treatment because of its effect in bringing about an increased supply of available nitrogen or nitrate for the crop growing on the soils. Turning the soil with the moldboard plow is the foremost tillage performance to increase nitrate production. Surface cultivation likewise stimulates nitrate production. . . .

"Fertilizers did not bring about any great change in the level to which nitrates were exhausted. Their effects were generally unnoticed in terms of the measurement of the nitrate nitrogen supply on the soil though there were suggestions that they encouraged early season nitrate accumulations and aided in the late season nitrate removals. . . .

"The most detrimental effect to nitrate accumulation in a fallow soil in these studies was manifested by the straw mulch. Under the application of 6 tons of straw per acre, the fallow soil failed to accumulate nitrates above the levels common in soils growing crops. This effect was not overcome when ni-

trogenous green manures were turned under in the form of sweetclover. The growth of corn in the straw-mulched soil was, however, the equivalent of that on unmulched soils where higher accumulations of nitrate occurred.

"Whether continuous cropping or crop rotation was practiced, the level of nitrate nitrogen under the same crop was but little disturbed as a general average. The nitrates under corn continuously were closely similar to those under corn alternated with a legume crop, to those under corn in a 3-yr. rotation handled as a livestock system of farming, and to those under the grain system of soil management. . . .

"Perhaps the most noticeable feature of the nitrate levels observed in this soil was the decline of the levels with time. Under the wheat or under the corn, and likewise under the fallow soils, both mulched and unmulched, the nitrate levels observed were lower as the years of the study advanced. This points forcibly to the decline in ability of this soil to deliver nitrates early in the season and at high levels as cropping continued. These levels had fallen so low that it was difficult to establish sod legumes such as red clover and sweetclover on these soils even with an application of finely ground limestone and commercial fertilizer. These declines represented reductions in levels as much as 50 percent, and should direct our attention to the significant speed at which the soil's power to produce nitrates is being depleted when such reductions occur within a period as brief as 13 yr."

Methods of incorporating organic matter with the soil in relation to nitrogen accumulations, W. A. ALBRECHT (*Missouri Sta. Res. Bul.* 249 (1936), pp. 16, figs. 8).—Analyses of soils sampled annually where 25 tons of clover (106.2 lb. of nitrogen) per acre were turned under each year and where this quantity was applied on the surface and turned under the following year showed that nitrogen accumulated slightly more rapidly in the latter than in the former treatment, the difference amounting to about 3 percent of the nitrogen applied.

"The study suggests that as a general average where clover is used for soil improvement in this manner, about one-third of the annual application may be considered as contributed to the residual or insoluble nitrogen supply in the soil, while two-thirds are mobilized or transformed into soluble forms. With these heavy annual applications of clover, the soil supply of nitrogen was raised above its initial content at a rate amounting to more than 20 percent of the annually applied nitrogen. Its effects in offsetting declines of nitrogen in the soil, added to this, make its effects in building up the soil nitrogen approach the rate of one-third of the nitrogen applied annually.

"These results were obtained on a shallow surface soil underlain by a plastic clay subsoil. Slight increases in the upper subsoil content of nitrogen resulted where significant increases occurred in the surface soil."

The tolerance of nitrate by pure cultures of *Azotobacter*, P. L. GARNEY (*Soil Sci.*, 42 (1936), No. 6, pp. 445-459).—The author reports from the Kansas Experiment Station that field and laboratory observations on the effect of nitrates upon the *Azotobacter* flora of soils tend to support the recorded observations that relatively high concentrations in a soil containing *Azotobacter* tend to cause a decrease in the density of the *Azotobacter* population. Observation of 65 pure cultures of *Azotobacter* isolated from local soils "has shown conclusively that there is a marked variation in the sensitivity of different strains to nitrate nitrogen. That this sensitivity is due to the NO_3 ion and not to the cation is indicated by the fact that the same injurious effect is produced by potassium, sodium, and ammonium nitrate. That the nitrogen alone is not responsible for the phenomenon is indicated by the fact that upon the addition of nitrogen in the form of urea the injurious effect is not evident

until sufficient time has elapsed to enable the processes of nitrification to transform the urea nitrogen into nitrate nitrogen; also by the fact that the injurious effect of ammonium nitrate is not proportional to the total but rather to its $\text{NO}_3\text{-N}$ content.

"With the toxic action of the NO_3 upon pure cultures established, it is not necessary to postulate an antagonistic action of other organisms stimulated by the nitrate to account for the reduction in *Azotobacter* population following an application of nitrate nitrogen to a soil. Some evidence is submitted . . . in support of the view that the variation in sensitivity of the *Azotobacter* of different soils may be associated with the sensitivity of the particular strains inhabiting the soil in question.

"Relative to the apparently much lower concentration of NO_3 that proved toxic to *Azotobacter* in soils, as compared with that necessary in case of pure cultures, attention should be directed to the fact that the nitrate content of soils is always recorded on a dry-soil basis. Since nitrates are very soluble, such salts are probably found dissolved in the soil moisture. The actual effective concentration, therefore, as far as the *Azotobacter* are influenced, would vary inversely with the moisture content of the soil, and in the data here presented would be from 3 to 20 times the concentration calculated upon a dry-soil basis. The fact should also be kept in mind that all the pure culture studies here recorded were made upon mannite agar. Just what influence the colloidal agar exerted upon the concentration of NO_3 tolerated by *Azotobacter* is problematic. . . .

"Since a relatively low concentration of $\text{NO}_3\text{-N}$ has been found toxic in soil and since the speed of the action . . . may be rapid, it is not impossible that the differences observed in the density of the *Azotobacter* population in 'fertile' and 'nonfertile' soils were due to differences in the $\text{NO}_3\text{-N}$ content that existed in the pair of samples at some time. In view of the relative ease with which increased tolerance can be induced in the laboratory, however, it is difficult to see why a natural tolerance to the concentrations of NO_3 ordinarily encountered in the more fertile soils, or in soils fertilized with nitrate nitrogen, is not developed."

Associative and antagonistic effects of microorganisms, I-III (*Soil Sci.*, 43 (1937), No. 1, pp. 51-92).—The three papers here noted form part of a serial contribution from the New Jersey Experiment Stations.

I. *Historical review of antagonistic relationships*, S. A. Waksman (pp. 51-68).—From a review of more than 100 papers the author concludes, in part, that "numerous organisms, comprising bacteria, fungi, actinomyces, and protozoa, bring about injurious or destructive effects upon themselves or upon other soil organisms. In some cases the injurious effect may be due to competition for nutrients, in other cases it is due to a change in the environmental conditions of the substrate, especially oxidation-reduction potential and reaction. More frequently it is due to the formation of substances which exert a definite toxic effect. The production of these toxic substances by various specific micro-organisms is greatly influenced by the reaction, temperature, and aeration of the substrate, as well as by the presence of other organisms. . . . Some of the soil organisms, notably the protozoa, are able to destroy directly other members of the soil population, especially the bacteria. This phenomenon need not be injurious, however, to the specific processes brought about by these bacteria. The claims concerning the effects of protozoa on soil processes, based upon their growth on artificial culture media, appear to be exaggerated. The available information concerning antagonism among micro-organisms may be useful in explaining the behavior of various specific organisms. It is little more than suggestive, however, in explain-

ing the . . . interrelationships of the numerous micro-organisms comprising the soil population and the equilibrium condition normally found to exist in this population."

II. *Antagonistic effects of microorganisms grown on artificial substrates*, S. A. Waksman and J. W. Foster (pp. 69-76).—The authors here report experiments showing that various soil organisms found among the fungi, actinomycetes, and bacteria are capable of producing, when grown on synthetic media, substances which are antagonistic to the growth of other soil organisms. In addition to a number of other mixed culture experiments, "a detailed study has been made of the antagonistic effect of one species of *Actinomyces* [designated '*Actinomyces* 3065'] upon a variety of fungi, bacteria, and other actinomycetes. The inhibiting effect produced by this organism was shown not to be due to exhaustion of nutrients or to unfavorable changes in reaction but was found to be specific in nature. The maximum production of the antagonistic substance took place in the cultures of the actinomycetes 7 to 18 days old. The substance was then gradually destroyed. Aeration and heat brought about rapid destruction of this substance."

III. *Associative and antagonistic relationships in the decomposition of plant residues*, S. A. Waksman and I. J. Hutchings (pp. 77-92).—This part of the series reports upon a study of the associative growth of different fungi, actinomycetes, and bacteria upon different plant materials and of the resultant decomposition of the latter.

"It was found that the presence of one organism may modify considerably the growth of another. The decomposition of alfalfa by a *Trichoderma* was modified considerably by the presence of various fungi and bacteria. These organisms, although by themselves unable to decompose cellulose, were capable of favoring the decomposition of the cellulose by *Trichoderma*. Cornstalks could not be attacked by pure cultures of actinomycetes. However, when certain fungi were previously grown upon this plant material, the growth of the actinomycetes was greatly favored. This was accompanied by increased decomposition. The unfavorable condition could also be corrected by the addition of lime, and only partly by nitrate and phosphate. Different fungi were found to vary considerably in their ability to attack the various chemical constituents of plant residues and to exert varying influences upon the activities of other organisms, as well as of the soil population as a whole. *Azotobacter* was found capable of utilizing the carbohydrates of oat straw, but it did not fix any nitrogen. In the presence of cellulose-decomposing fungi it also made good growth, but this process, as well, was not accompanied by nitrogen fixation. The combined nitrogen of the straw was utilized by this organism for its synthetic needs. Lignin decomposition took place only when actinomycetes were present in the mixture of organisms."

Formamide as a nitrogenous fertilizer, C. J. REHLING and J. R. TAYLOR, JR. (*Jour. Amer. Soc. Agron.*, 29 (1937), No. 2, pp. 134-144, figs. 3).—According to experimental results, reported from the West Virginia and Alabama Experiment Stations, "ammonification of formamide was generally complete for 2 days in the soil. Nitrification of formamide and ammonium formate proceeds in the soil in the same manner as that of urea. Formamide, urea, and various formates were found to be decomposed into carbonates in 2 to 6 days in the soil, depending upon soil fertility. Greenhouse and field cropping studies indicated equal efficiency of formamide-containing and formamide-free mixed fertilizers in increasing crop growth."

Potassium retained in the exchangeable form by some Maryland soils, R. P. THOMAS and J. E. SCHUELER, JR. (*Jour. Amer. Soc. Agron.*, 29 (1937), No. 1, pp. 17-22).—The authors determined, at the Maryland Experiment Station, the

exchangeable potassium content of the Sassafras, Manor, Penn, Berks, and Hagerstown soil series in orchards undergoing fertilizer tests. The potassium added in the fertilizers annually during the 4 yr. of these tests had ranged, at the time of sampling, from 230 to 970 lb. per acre. The determinations were made in the first, second, and third 6-in. layers.

"The results . . . indicate that light-textured soils are unable to retain large amounts of exchangeable potassium. The subsoils have an even smaller retention capacity. Unless the exchange complex of these soils is increased by incorporating organic matter, potash fertilizer should not be applied in large amounts but more often. The movement of potassium in the heavy-textured soils was much less than in the light-textured soils. The slow movement of this ion is probably due to the high exchange capacity of these soils. This does not necessarily indicate that these soils should receive a large potash fertilization. The movement of this element in the silt loam soils was intermediate between the sandy and clay soils."

The influence of phosphate fertilization upon the amphoteric properties of Coastal Plain soils, J. B. HESTER (*Jour. Amer. Soc. Agron.*, 29 (1937), No. 1, pp. 10-16).—The author discusses, in a communication from the Virginia Truck Experiment Station, the phosphate-absorbing power of the soils, the availability of phosphorus, the clay composition and phosphate solubility, the phosphate-fixing power of the Norfolk soil used in these experiments, and the mechanism of phosphate fixation, and concludes from the data given that "the seat of the phosphate-absorbing power of the soil is in the basoid constituent of the soil colloid."

Suitable fertilizer mixtures for different crops, including the functions of chief plant nutrients, W. H. RANKIN (*North Carolina Sta. Agron. Inform. Circ.* 103 (1937), pp. [1]+11).—Home-made fertilizer mixtures considered suitable for various combinations of soil and crop are suggested.

Garden fertilizers, W. B. BALCH (*Kans. State Hort. Soc. Bien. Rpt.*, 43 (1934-35), pp. 182, 183).—This is a brief popular article from the Kansas Experiment Station, including barnyard manures, cover crops, and other decaying organic matter, and commercial fertilizers.

Analyses of commercial fertilizers, A. P. BRUCE and E. BURKE (*Montana Sta. Bul.* 331 (1937), pp. 12).—This bulletin is the first report on fertilizer analyses published by the station as a result of the State fertilizer law of 1931, amended to provide for such publications in 1935. The amended law is quoted and discussed, terms are defined, and the analyses are very briefly discussed.

Inspection of commercial fertilizers for 1936, T. O. SMITH and H. A. DAVIS (*New Hampshire Sta. Bul.* 294 (1936), pp. 12).—This bulletin contains the usual analytical report on the fertilizers offered for sale in 1936 (*E. S. R.* 75, p. 179).

Analyses of commercial fertilizers, fertilizer supplies, and home mixtures for 1936, C. S. CATHCART (*New Jersey Sta. Bul.* 619 (1936), pp. 31).—The greater part of the fertilizer analysis data for 1936 is included in the present bulletin, together with cost per pound of the plant-food element in various single plant-food sources of nitrogen, phosphate, and potassium. Data for home mixtures as well as for commercial fertilizers are given.

AGRICULTURAL BOTANY

[Botanical work by the Florida Station] (*Florida Sta. Rpt.* 1936, pp. 62, 94).—Data are presented on nutrient salt concentration in the soil, with special reference to the trace elements, by R. B. French; and on the collection and preservation of specimens of Florida plants, by E. West and L. Arnold.

[Botanical studies by the Pennsylvania Station] (*Pennsylvania Sta. Bul.* 336 (1936), pp. 13, 14, 27, 28, fig. 1).—Brief reports are given on a photoelectric apparatus for measuring leaf areas, by D. E. H. Frear; and ultraviolet radiation of plants, by H. W. Popp.

A bibliography on the use of photoelectric cells in plant investigations, F. M. TURRELL and L. WALDBAUER (*Iowa Acad. Sci. Proc.*, 42 (1935), pp. 67-70).—The authors offer this bibliography of nearly 4 pages in the hope of bringing together recent developments (many since 1931) in a form usable to plant physiologists and others interested in colorimetric, turbidimetric, and various light measurements.

The polygonal presentation of polyphase phenomena, A. H. HUTCHINSON (*Roy. Soc. Canada Trans.*, 3. ser., 30 (1936), Sect. V, pp. 19-26, pls. 3).—Apropos of the subject of graphical representation of biological data, the author first delimits the problem and then proceeds to discussions of the development of polygonal charting, polygonal graphing of physiological data, the graphing of oceanographic data, the graphing of the characteristics of families of plants and animals, and further developments of polygonal graphing. The construction and interpretation of polygonal graphs are also treated, and examples are given.

Some remarks on the photosynthesis of green plants, J. WEISS (*Jour. Gen. Physiol.*, 20 (1937), No. 3, pp. 501-509).—This is a critical review and discussion from which "it is suggested that in the assimilation process of green plants the reduction of the CO_2 takes place with the help of Fe^{++} ions (present in the chloroplast) under the influence of light, which is absorbed by a sensitizing chlorophyll- CO_2 -complex. It seems that the chlorophyll has to fulfill two different functions depending on its situation in the chloroplast. The chlorophyll molecules on the surface of the lipid phase (in contact with an aqueous phase containing Fe^{++}) combine with CO_2 to form a light absorbing chlorophyll- CO_2 -complex and in this way take part in the reduction of the CO_2 . The light energy is also absorbed by the greater portion of the chlorophyll, which is dissolved in the interior of the lipid phase, and eventually handed over to the chlorophyll molecules on the surface. The photosynthetic unit of Emerson and Arnold [*B. S. R.*, 74, p. 761] may be determined by the ratio: (Active) chlorophyll in the surface of the lipid phase/chlorophyll dissolved in the interior of the lipid phase, so that for every chlorophyll molecule on the surface there are about 500 molecules in the interior, which provide it with the necessary quanta."

The light factor in physiological processes [trans. title], A. SERNOLD (*Jahrb. Wiss. Bot.*, 82 (1936), No. 5, pp. 741-795, figs. 20).—The author considers the physiological effects of light quality and quantity from different parts of the spectrum on sun, shade, and water plants; compares artificial light in these respects; and discusses the light field in nature and under experimental conditions with reference to the germination of seeds and of fern spores, in relation to deciduous leaves and to transpiration resistance, and the light absorption of carotinoids.

The inner daily rhythm as the basis of photoperiodic reactions [trans. title], E. BÜNNING (*Ber. Deut. Bot. Gesell.*, 54 (1936), No. 10, pp. 590-607, figs. 4).—The photoperiodic effect is said to arise through a lack of agreement between the inner and outer rhythms. Light reacts favorably on the reproductive development as long as the plants remain in the morning phase of the inner rhythm (recognizable in the rising upward of the leaves), but in an inhibitory manner during the evening phase (recognizable in the lowering of

the leaves). From the literature and the results of the author's work, it is concluded that the physiological basis of photoperiodism lies in the inner rhythm.

The effect of temperature upon the responses of plants to photoperiod, R. H. ROBERTS and R. E. STUCKMEYER (*Science*, 85 (1937), No. 2203, pp. 290, 291).—In experiments at the University of Wisconsin with over 100 varieties of plants grown under a range of controlled photoperiods, temperatures, and some other variables, it was found that temperatures a little above or below the usual range employed in greenhouse culture altered the type of response of some of the plants with respect to length of day. Poinsettias, for example, in winter short days bloomed normally at 60°–65° F., but at 5°–8° lower showed little tendency to bloom, while at temperatures as much higher they remained strongly vegetative. Altered responses were also met with in Klondyke cosmos, *Rudbeckia*, "alfalfa (seed setting), winter barley, castor-beans, wax beans, Chinese cabbage, chrysanthemum, white clover, geranium, hemp, jimsonweed, lettuce, pansy, pigweed, spring rye, spinach, stock, timothy, and spring wheat."

The effect of alternate periods of light and darkness of short duration on the growth of the cucumber, G. B. PORTSMOUTH (*Ann. Bot. [London]*, n. ser., 1 (1937), No. 1, pp. 175–189, figs. 6).—The much lower growth rate with short-period intermittent light was shown to result from reduction in the maximum size of the individual leaves produced and from delay in unfolding of the successive leaves. The main effect of variation in the period of alternation proved to be due to variations in net assimilation rate per unit area. The carbohydrate supply appeared adequate to maintain leaf growth near the optimum both under continuous light and with 12-hr. alternations. Observations of stomatal aperture showed part, at least, of the differences in assimilation rates to be due to their closure with the 1-min. alternations.

The necessity of a considerable period of darkness for the maintenance of high assimilation rates is postulated in explanation of the results presented.

The influence of environment on the growth and metabolism of the tomato plant.—II, The relationship between water content and assimilation, R. MELVILLE (*Ann. Bot. [London]*, n. ser., 1 (1937), No. 1, pp. 153–174, figs. 8).—Continuing this series,² it is shown that "the percentage water content of the leaves at the beginning of a period of assimilation gives an indication of the effect of internal factors on the subsequent assimilation. The internal factors are dependent on the previous history of the plant."

Limited growth and abnormalities in excised corn root tips, W. J. ROBINS and V. B. WHITE (*Bot. Gaz.*, 98 (1936), No. 2, pp. 209–242, figs. 6).—Excised root tips in solution C ($\text{Ca}(\text{NO}_3)_2$, MgSO_4 , KH_2PO_4 , FeCl_3 , and dextrose) gave limited growth and sometimes became abnormal. Similar results followed the use of a modified Pfeffer solution containing dextrose. The amount of growth in solution C varied with the brand of dextrose, even with dextrose of high purity, and substitution of levulose, sucrose, xylose, or maltose was of no benefit. In fact, xylose and maltose gave very poor growth. Growth was improved by addition to solution C of Difco agar, aqueous extracts of agar, qualitative filter paper or its aqueous extracts, soluble starch, autolyzed or dried brewers' yeast, or a mixture of salts of manganese, boron, and zinc. Best results were obtained by addition of qualitative filter paper. Exposure of excised root tips originally 1 cm long for 24 or 48 hr. on the surface of a semisolid

² Bolas, B. D., and Melville, R. *Ann. Bot. [London]*, 47 (1933), No. 187, pp. 673–698, figs. 14.

agar medium or on moist qualitative filter paper markedly favored their later growth in solution C. Exposure in a moist chamber or washing the tips in redistilled water before culture in solution C failed to benefit. Recutting excised roots after pretreatment on filter paper failed to affect later growth in this solution. Increased aeration in the liquid medium increased the growth and delayed the appearance of abnormalities. Reducing the acidity, increasing the salt concentration, substituting ferric tartrate or citrate for FeCl_3 , adding quantitative filter paper, absorbent cotton, CuSO_4 , thallium nitrate, glutathione, or vitamin B failed to benefit, but pantothenic acid was beneficial in some cases. Pfeffer or Uspenski solutions, or the solution used by P. R. White for culture of excised tomato roots, proved no more effective than solution C.

The maximum growth of individual excised root tips 1 mm long was 61.2 cm (0.9 cm per 24 hr.); of root tips 2 mm long, 85.0 cm (1.4 cm per 24 hr.); and of root tips 10 mm long, 98.2 cm (2.4 cm per 24 hr.).

It is believed that the poor growth in solution C and the like results from a deficiency, a part of which, at least, is inorganic.

A bibliography of 18 titles is appended.

Ecological and physiological studies on the blooming of oat flowers. G. MISONOO (*Jour. Faculty Agr., Hokkaido Imp. Univ.*, 37 (1936), No. 4, pp. 211-337, pl. 1, fig. 1).—This monograph presents the results of a comprehensive study of the relations of environmental factors (temperature, humidity, rainfall, wind, and sunlight) to blooming, the control of blooming, and the physiological and chemical changes involved. An appendix (36 pages) presents tabulated data, and a bibliography of 42 titles is appended.

The electrometric determination of plant quality, using potato tubers.—II, **Investigations on the acidity of macerated tissue of potato tubers** [trans. title], H. WARTENBERG, A. HEY, and A. TAHSIN (*Arb. Biol. Reichsanst. Land u. Forstw.*, 21 (1935), No. 4, pp. 499-516, figs. 2).—Continuing this series of studies (E. S. R., 75, p. 459), the results led to the belief that the acidity of the macerated tissues is controlled by a carbonate-bicarbonate system and that the differences in plant-quality potential are influenced but little by differences in acidity. The potential measured is therefore probably the reduction-oxidation potential.

The electrometric determination of plant quality, using potato tubers.—III, **The redox potential of macerated tissue of potato tubers** [trans. title], H. WARTENBERG and A. HEY (*Planta, Arch. Wiss. Bot.*, 25 (1936), No. 2, pp. 258-281, fig. 1).—The authors present discussions of the effects of different amounts of atmospheric oxygen on the potential, the significance of melanin formation as a natural and automatic control on the production of the anaerobic state, the phenomenon and theory of electrolyte action, the effect of electrolyte addition on the value of the constant potential, and the question of potential constancy.

The electrometric determination of plant quality, using potato tubers.—IV, **The redox potential of a suspension of macerated tissue of potato tubers as an index of degeneration** [trans. title], H. WARTENBERG and A. HEY (*Phytopath. Ztschr.*, 9 (1936), No. 6, pp. 531-569, figs. 16).—Macerated tissue suspensions of tubers with degeneration diseases gave a more negative potential value than those from sound tubers.

The nitrogen nutrition of green plants. G. T. NIGHTINGALE (*Bot. Rev.*, 3 (1937), No. 3, pp. 85-174).—In this review the subject is discussed under the following headings: Synthesis and hydrolysis of storage proteins, synthesis and hydrolysis of leaf proteins, metabolism of stems, and new synthesis of organic nitrogen from nitrogenous nutrients, storage and assimilation of

nitrate, external factors influencing ammonium and nitrate nutrition, internal factors influencing ammonium and nitrate nutrition, comparative metabolism of ammonium- and nitrate-supplied plants, nitrite nutrition, absorption of organic compounds of nitrogen, growth in relation to available nitrate, effects of temperature on nitrate nutrition, and effects of day length on nitrate nutrition.

Three hundred and five references to the literature are cited.

Zinc as an essential element for sugar beets and potato plants. D. V. VAN SCHREVEN (*Meded. Inst. Suikerbieten.*, 7 (1937), No. 1, pp. 26, pls. 2; *Eng. abs.*, pp. 18-21).—Following a review of the literature (with a bibliography of 80 titles), the author describes the methods and results of his own water-culture experiments with and without zinc.

Potato plants deprived of zinc remained behind in growth, and the leaves had the primary symptoms of leaf roll disease and were discolored and spotted. Histological and macroscopic comparisons of plants with and without zinc are discussed in detail. The differences in height of the plants, in foliage and tuber weights, and in average total plant weights were significant, but the difference between root weights was not.

Similar comparisons are made for the tests with sugar beets. Here the differences in taproot weight, relation of foliage and taproot weights, and in sugar content were significant, while the difference in average weight of foliage was not. The dry matter content of the foliage and taproots of the plants with zinc appeared to be higher, but the ash content of the foliage and roots was slightly lower than for the zinc-deficient plants.

Histological reactions of bean plants to indoleacetic acid. E. J. KRAUS, N. A. BROWN, and K. C. HAMNER (*Bot. Gaz.*, 98 (1936), No. 2, pp. 370-420, figs. 33).—Living cells of the stem of red kidney bean are shown to be responsive to applications of indoleacetic acid, the mixture used consisting of 80 mg of indoleacetic acid per gram of pure lanolin. Gross observations over several weeks were made on the untreated and treated stems without removal from the plant, and histological studies were carried out on material collected and preserved at 6-hr. intervals up to a total of 168 hr. The results obtained (described and illustrated in great detail) led to the conclusion that the histological developments following application of indoleacetic acid closely resemble many of those associated with crown gall induced by *Bacterium tumefaciens* [= *Phytoplasma tumefaciens*].

"The most striking feature shown by stems treated with lanolin mixture is the very great speeding up of nuclear divisions, especially in cells near the surface of application. Such divisions result in a multinucleate condition of many of the cells. Later cell division occurs, and the derived cells may remain highly meristematic for long periods of time. It does not seem essential to assume that the developmental patterns expressed by tissues following treatment necessarily result from an effect altering the genetic composition of the chromosomes to the degrees that parts of chromosomes or whole chromosomes have been lost."

Retarded germination in the seed of *Hypericum perforatum* caused by calcium. H. A. BORTHWICK (*Bot. Gaz.*, 98 (1936), No. 2, pp. 270-282, figs. 6).—Studies at the University of California indicated that tap water retarded germination as contrasted with distilled water. Mixtures of the two containing as little as 10 percent tap water caused as pronounced germination delay as pure tap water. A relatively short period in tap water, followed by transfer to distilled water, also resulted in definite retardation. High alkalinity of the tap water and its ionic constitution are both considered as possible causes, but the data obtained indicate that it was the calcium present rather than the alkalinity per se which was responsible.

No conclusive explanation is offered as to the mechanism of these calcium effects, but the results suggest that the permeability of the seed coat to water becomes altered.

Effect of alternate moistening and drying on germination of seeds of western range plants. S. M. GRISWOLD (*Bot. Gaz.*, 98 (1936), No. 2, pp. 243-269, figs. 9).—The seeds used comprised 9 grass, 26 weed, and 7 woody species of Utah range plants, of which 23 gave little or no germination at 22°-29° C.

The effect of alternate moistening and drying varied with the species. Of the 19 species germinating at 22°-29°, such treatment had little effect on the germination of *Bromus polyanthus*, accelerated that of *Stipa lottermani*, *Artemisia incompta*, *Lepidium densiflorum*, and *Plantago tweedyi*, and decreased that of *Geranium viscosissimum*, *Pseudocymopterus montanus*, *Chrysanthamnus lanceolatus*, and *S. columbiana*. Rapid drying affected but little the germination of *Poa interior*, *P. secunda*, and *Chenopodium album*, but increased that of *Achillea lanulosa*, *Androsace diffusa*, *Pentstemon rydbergii*, and *Rumex mexicanus*. In all these species slow drying lowered the germination percentage. Rapid drying decreased the germination of *B. anomalus*, *Lupinus parviflorus*, and *Rudbeckia occidentalis*, while slow drying increased it in *Rudbeckia* but had little effect in *B. anomalus* or *Lupinus*. Increased germination was usually accompanied by a hastening of the germinative process and decreased germination by a retardation. However, in *Poa secunda* (No. 1), *Androsace*, *Plantago*, *Rudbeckia*, and *Rumex*, retardation was followed by increased germination.

Some seeds, after water absorption, withstood short periods of alternate drying and moistening and others withstood long periods of drying without injury. The time at which drying begins in relation to the stage of development of the germinating seed is a very important factor for determining whether drying is harmful or beneficial. The effect of drying is also influenced by its rate.

Researches on the ascent of sap [trans. title], L. HAUMAN (*Acad. Roy. Belg., Ol. Sci. Mém.*, 12 (1934), No. 7, pp. 83, figs. 5).—The discussions in this monograph center around the entry of air into the vessels, the role of living cells, the nature of the forces concerned in the ascent of sap (gravity, osmosis, and imbibition), and extravascular circulation. A bibliography of 28 titles and a list of the 60 plant species, varieties, and forms used in the investigation are included.

The physico-chemical properties of plant saps in relation to phytogeography: Data on native vegetation in its natural environment, J. A. HARRIS (*Minneapolis: Univ. Minn. Press*, [1934], pp. VI+339).—This volume was compiled from original records and edited by a committee of the author's colleagues in the University of Minnesota, comprising G. O. Burr, R. A. Gortner, and C. O. Rosendahl (chairman).

Part 1, papers on the physicochemical properties of plant saps in relation to phytogeography, includes the following: Physical chemistry in the service of phytogeography, and the physicochemical properties of plant tissue fluids—their significance in physiology, phytogeography, and organic evolution, both by Harris, with accompanying memoranda giving a partial list of habitats for which extensive series of physicochemical determinations of plant fluids are already available, physiological and chemical investigations already under way, genetic phases of the investigation already under way, and a bibliography of published papers on the physicochemical properties of plant tissue fluids; and the importance of phytochemical studies in the field of plant geography, by H. L. Shantz. Part 2, experimental data on the physicochemical properties of the plant saps of the native vegetation, concerns the collection of data,

explanation of the code used in the tabulations, and the presentation of detailed data for the western United States and the Hawaiian Islands and for the eastern United States and Jamaica. Part 3, descriptions of stations at which specimens were collected, includes the common names used and their botanical equivalents, and a presentation of detailed data for the western United States and the Hawaiian Islands and for the eastern United States and Jamaica.

An index to the experimental data is provided.

The influence of cell-wall composition on the physical properties of beech wood (*Fagus sylvatica* L.), S. H. CLARKE (*Forestry*, 10 (1936), No. 2, pp. 143-148, pl. 1, fig. 1).—Under certain conditions the fiber walls of beech and many other hardwoods develop peculiar thickenings called "gelatinous layers" or "tertiary walls." It is shown that samples with large proportions of these abnormal thickenings usually have low strength values in compression parallel to the grain, and that the wall composition is apparently more important than specific gravity in influencing strength. It is also shown that cell-wall composition is capable of influencing the shrinkage and working properties of beech.

The literature of mycorrhizae: A compendium of our knowledge of fungus roots, A. P. KELLY (*Landenberg, Pa.: Landenberg Lab., 1937, pp. 306*).—This mimeographed work presents digests of the mycorrhizal literature of the world, arranged alphabetically by authors. The general index provided does not include "hosts" or fungi.

Longevity of legume bacteria (*Rhizobium*) in water, W. A. ALBRECHT and T. M. MCCALLA (*Jour. Amer. Soc. Agron.*, 29 (1937), No. 1, pp. 76-79).—The results of this study at the Missouri Experiment Station suggest that apprehension regarding the rapid destruction of *Rhizobium* cultures in tap water in closed containers is unwarranted, and that failures in tap water transfer of cultures can scarcely be ascribed to the water treatment. Since tap water is actually an aqueous extract, the results appear to indicate that even in such a dilute mineral solution of the soil, with its consequent low oxygen content, the legume bacteria maintain themselves for a long time in the absence of the host.

GENETICS

A portable chamber for treating plants with heat, R. A. BRINK (*Jour. Amer. Soc. Agron.*, 28 (1936), No. 12, pp. 1021, 1022).—Using the apparatus described, S. Atwood, working on *Melilotus alba* in the author's laboratory at the Wisconsin Experiment Station, obtained one tetraploid plant with $2n = 32$ chromosomes and one aneuploid individual with $2n = 24$ chromosomes from 575 seeds treated in the early embryonic stages.

Tetraploid and aneuploid *Melilotus alba* resulting from heat treatment, S. ATWOOD (*Amer. Jour. Bot.*, 23 (1936), No. 10, pp. 674-677, figs. 17).—Biennial *M. alba* was subjected at the Wisconsin Experiment Station to heat treatment at the time of the division of the zygote and proembryo. In a population treated at from 40° to 41° C. for 30 min. one tetraploid ($n = 16$, $2n = 32$) was found. It formed quadrivalents, but the chromosomes segregated regularly in meiosis and it was almost completely self-fertile. In a population treated at from 38° to 40° for 20 min. an aneuploid ($n = 12$, $2n = 24$) was found. This formed some quadrivalents at meiosis and showed only occasional irregular distributions, but was only slightly self-fertile.

Genetic effects of ultra-violet radiation in maize, I-III, L. J. STADLER and G. F. SPRAGUE (*Natl. Acad. Sci. Proc.*, 22 (1936), No. 10, pp. 572-591).—These contributions are presented from the U. S. Department of Agriculture and the Missouri Experiment Station, working in cooperation.

I. *Unfiltered radiation* (pp. 572-578).—Ultraviolet radiation applied to corn pollen increased greatly the frequency of both entire and fractional endosperm deficiencies. Deficiencies affecting the *F₁* plants also were induced by the treatment and many were haplo-viable. No significant increase was noted in the frequency of translocation. Several of the numerous point mutations affecting seed and seedling characters induced occurred in treated germ cells in which apparently unrelated mutations or other germinal alterations also took place.

II. *Filtered radiations* (pp. 579-583).—Results with filtered radiations applied to corn pollen indicate that $\lambda 3130$ and longer wave lengths are relatively ineffective in inducing deficiency, and that $\lambda 3022$ and shorter wave lengths are effective, $\lambda 3022$ probably being less effective than shorter wave lengths. Although radiation of effective wave length sometimes is present in low intensity in sunlight, the occurrence of various genetic alterations in the controls (shielded from sunlight) showed that exposure of the pollen to sunlight is not the sole cause of naturally occurring deficiencies and mutations. The frequency of entire endosperm deficiencies of *A* and *Pr* induced by the ultraviolet radiations applied was about equal, while the frequency of induced fractional endosperm deficiencies was much higher for *A* than for *Pr*. The frequency of germless seeds induced by the ultraviolet radiations applied was low, and decreased with decreasing relative intensity of the shorter wave lengths.

III. *Effects of nearly monochromatic $\lambda 2537$, and comparison of effects of X-ray and ultra-violet treatment* (pp. 584-591).—Comparable trials of mercury discharge tube radiation (largely $\lambda 2537$) and filtered mercury arc radiations (largely $\lambda 2967$ and $\lambda 3022$ plus various genetically ineffective wave lengths) indicated that the relative frequency of induced deficiency at the various loci tested does not differ appreciably for the longer and shorter wave lengths. The maximum dose tolerated is much lower for the shorter wave length. The frequency of induced deficiency per unit of energy applied at the surface of the pollen grain is much higher for the shorter wave length. The difference between the wave lengths compared in effect on the frequency of germless seeds is even more extreme. Comparing doses which induced deficiency in approximately equal frequencies, the shorter wave length radiation produced several times as many germless seeds as the longer wave length radiation.

Comparable trials of X-rays (1333 r) and filtered mercury arc radiations (various doses) indicated that almost all X-ray-induced deficiencies affect the endosperm as a whole, while a large proportion of ultraviolet-induced deficiencies are fractionals affecting approximately half of the endosperm. The frequency of entire endosperm deficiencies of *A* was much higher than that of *Pr* following X-ray treatment, but *A* and *Pr* deficiencies were about equally frequent following ultraviolet treatment. The frequency of germless seeds produced by X-rayed pollen exceeded that produced by ultraviolet-treated pollen. Additional contrasts between ultraviolet and X-ray effects indicated by the experiments but not yet tested in strictly comparable trials are listed.

Hybrid vigor and growth rates in a maize cross and its reciprocal, G. F. SPBAGUE (*Jour. Agr. Res. [U. S.]*, 53 (1936), No. 11, pp. 819-830, figs. 3).—The growth rates of later generations of the two inbred strains of corn (228-4-8, 228-6-5) used by Ashby (*E. S. R.*, 68, p. 602) and their reciprocal hybrids were studied cooperatively by the U. S. Department of Agriculture and the Missouri Experiment Station.

By dividing the growth period from fertilization to maturity of the corn plant into three phases—(1) from fertilization to maturity of seed, (2) from germination through the early seedling stage, and (3) from the late seedling

stage to maturity—it was shown that the hybrids grew faster than either parent during the first two phases of growth. Differences in the growth rate during the third period were not established statistically because of large sampling errors. In the first two phases the inheritance of growth rate could not be ascribed to a complex from one parent only; the rate must represent the action, complementary or additive, of factors from both parents. The reciprocal hybrids were alike in growth rates and in total amounts of growth. Within a genotype, embryo weights were found of little importance in determining final weight, since initial differences in embryo weight failed to persist. Hybrid vigor could not be attributed to the maintenance of an initial difference in embryo size. The differing growth rates for the three phases of growth, the author concludes, are readily explained on the basis of the complementary action of dominant genes.

Kindred work of Ashby and of Lindstrom (E. S. R., 73, p. 764) is discussed briefly.

Differential fertilization in the Bt Pr linkage group of maize, C. R. BURNHAM (*Jour. Amer. Soc. Agron.*, 28 (1936), No. 12, pp. 968-975).—Data presented in this contribution from the West Virginia Experiment Station indicated that a gene closely linked to *bt* acts upon the pollen of heterozygous corn plants in such a way that relatively large deficiencies for one allelomorph result. The *Ga* allelomorph must either produce something which speeds up germination or growth of pollen tubes carrying this allelomorph, or something which retards those carrying *ga*. Evidence that this gene must be considered as a dominant and that it acts as a differential in the pollen only when the silks carry the gamete gene is presented. Results from selfs and reciprocal backcrosses of plants heterozygous for *bt* and carrying the disturbing factor indicated that the deviations in the selfed ears were not due to the presence of a linked egg or pollen lethal. Examination of the pollen showed that certain lines were partially sterile, but indicated no relation to the deficient ratios.

Comparison of ratios given by *Bt* non-cross-overs and by *Bt* cross-overs between the *pr* and *bt* loci indicated that a second such gamete gene may be present in certain stocks. The first gene, *Ga*, is closely linked with *bt*, but the data conflict as to the side of *bt* on which it is located. The second gene appeared to be nearer to *pr*. In the case described by Emerson (E. S. R., 70, p. 757), *Ga* was relatively loosely linked with *su* (30.9 percent recombination), but only a small percentage of *ga* pollen was effective. In the present case there is close linkage with *bt*, but *ga* pollen functions to a much greater extent, the ratios resulting from selfing heterozygous plants depending largely on pollen tube germination or growth.

A second-chromosome gene, *Y*, producing yellow endosperm color in maize, H. S. PERRY and G. F. SPRAGUE (*Jour. Amer. Soc. Agron.*, 28 (1936), No. 12, pp. 990-996).—Yellow endosperm coloration in corn was observed to depend upon the interaction of the dominant allelomorphs of *y*₁ and *y*₂. Genetic tests indicated that *Y*₂ is closely linked with *al*, a chlorophyll deficiency type termed albescent. Trisomic tests showed both *al* and *y*₂ to belong in the second linkage group, and both appeared to be near *lg*₂ within the chromosome.

Genotypic control of chromosome size, P. T. THOMAS (*Nature [London]*, 138 (1936), No. 3488, p. 402, fig. 1).—The occurrence of chromosomes of double normal size in a male sterile specimen of perennial ryegrass (*Lolium perenne*) is described. Indications were that chromosome size is subject to Mendelian segregation.

Cytogenetic notes on cotton and cotton relatives, II, J. M. WEBBER (*Scienca*, 84 (1936), No. 2182, p. 378).—Additional cytological studies (E. S. R., 72, p. 461), made on a number of F_1 hybrids between different cottons, showed that the "chromosome complement at the reduction division is generally composed of: (1) Thirteen pairs of hybrids between cultivated Asiatic species and *Gossypium anomalum*, and in hybrids between wild American species and *Thurberia thespesioides*; (2) 13 pairs and 13 single chromosomes in hybrids between cultivated American species and *T. thespesioides*, and in hybrids between cultivated American species and *Gossypium anomalum*; (3) from 0 to 8 pairs with from 10 to 26 single chromosomes in hybrids between cultivated Asiatic species and *G. stocksii*, and between cultivated Asiatic species and *G. sturtii*; (4) 26 single chromosomes in hybrids between cultivated Asiatic species and *Thurberia thespesioides*." These findings seemed to support Skovsted's assumption (E. S. R., 71, p. 457) that the cultivated American cottons were derived from a cross between a wild American species and a species having a chromosome complement similar to that of the cultivated Asiatic cottons. The view that *T. thespesioides* is congeneric with *Gossypium* also was strongly supported. See also another note (E. S. R., 75, p. 189).

The occurrence of striped-leaved plants from a cross between two varieties of oats, H. H. LOVE and W. T. CRAIG (*Jour. Amer. Soc. Agron.*, 28 (1936), No. 12, pp. 1005-1011, figs. 2).—The behavior of striping as found in plants from a cross between Ruakura oats and a strain of *Avena sterilis macrocarpa* was studied at Cornell University in cooperation with the U. S. Department of Agriculture. Occurrence of 17 striped plants out of a total of 386 plants in the F_2 generation suggested an approach to a 15:1 ratio, but later results obtained from the F_3 generation proved otherwise. Further results from crosses in which striped plants were pollinated with pollen from fully green plants and also from the reciprocal crosses showed that the behavior of the chlorophyll deficiency is apparently cytoplasmic in nature and not to be explained as due to the chromosomes.

An anthocyanin inhibitor in rice, B. S. KADAM (*Jour. Heredity*, 27 (1936), No. 10, pp. 405-408).—An anthocyanin gene, *A*, produces pigment all over the rice plant, making the plants entirely purple. Its action is limited by a partially inhibiting gene, *I*, which suppresses color in the leaf region but allows development of pigment in other parts.

A developmental analysis of inherited shape differences in cucurbit fruits, E. W. SINNOTT (*Amer. Nat.*, 70 (1936), No. 728, pp. 245-254, figs. 4).—The author distinguishes four distinct types of shape determination in cucurbits and states that all four are independent of each other in inheritance. The genes that control these shapes evidently differ in the time that the major effect is produced and in the character of the effect itself. Practically nothing is known at present as to the developmental mechanisms concerned in any of the four types of shape determination.

Chromosome structure in Tradescantiae.—VII, Further observations on the direction of coiling in Tradescantia reflexa Raf., B. R. NEBEL and M. L. RUTILE (*Amer. Nat.*, 70 (1936), No. 728, pp. 226-236).—In this contribution from the New York State Experiment Station, the authors summarize as follows:

"In an X-rayed strain of *T. reflexa* showing rings or chains of two, four, and six chromosomes, respectively, serial observations indicate that the direction of coiling tends to fall into certain patterns within a given half-anther. These patterns do not necessarily belong to given chromosomes or parts of chromosomes but appear to belong to a given group of chromosomes. Random coiling is thus considered to be modified within an anther. Similarity of patterning between half-anthers is suggested, but over a long period and

with a sufficient number of observations the various patterns between different anthers may form a random series."

Chromosome structure.—IX, *Tradescantia reflexa* and *Trillium erectum*, B. R. NEBEL and M. L. RUTTLE (*Amer. Jour. Bot.*, 23 (1936), No. 10, pp. 652-663, figs., [24]).—This is a contribution from the New York State Experiment Station.

New results of twinning investigations in cattle, C. KRONACHER and D. SANDERS (*Neue Ergebnisse der Zwillingsforschung beim Rind. Berlin: Paul Parey, 1936, pp. 172, figs. 233*).—The author describes the similarity found in the morphological characteristics, including body measurements of several pairs of supposedly single-egg twins in cattle.

New data about the chromosome number in domestic sheep, G. M. POEKADEZ (*Compt. Rend. (Dok.) Acad. Sci. U. R. S. S., n. ser., 3 (1936), No. 7, pp. 333, 334, fig. 1*).—The diploid chromosome number for Georgian fat-tailed sheep was found to be 60, in studies at the Ukrainian Academy. A footnote states that N. Butarin also found this number in an arkhar, fat-rumped ram and the F₁ hybrids.

The genetics of the Wensleydale breed of sheep.—II, Colour, fertility, and intensity of selection, F. W. DEX (*Jour. Genet.*, 33 (1936), No. 1, pp. 123-134).—Further studies are reported on the inheritance of color in Wensleydale sheep (*E. S. R.*, 52, p. 332). These sheep are white, black, or silver-gray, although blacks have never been allowed to breed. The deep blue color in the ears of white sheep was indicative of the heterozygous condition, as was the pale color in the ears indicative of homozygotes. Evidently, selection was generally for heterozygous ewes. An analysis of the fertility in the single flock showed that it was very high, production being 1.71 lambs per ewe among 1,623 ewes which were mated. In breed crosses, the high fertility of the Wensleydale was transmitted by rams to their daughters. On account of the color standard for the breed, selection of breeding animals is severely limited.

The incidence of kemp in the fleece of Scottish Mountain Blackface sheep, with special reference to inheritance, D. M. BRYANT (*Empire Jour. Expt. Agr.*, 4 (1936), No. 14, pp. 165-185, pls. 2, figs. 11).—The results obtained in this study at the University of Edinburgh give evidence that the incidence of kemp fibers in the fleece of Scottish Mountain Blackface sheep is an inherited character. An analysis of the percentage of kemp in the fleece of the rams, ewes, and the resulting offspring in 57 matings indicates that neither the nonkempy condition nor the grossly kempy condition behave as a Mendelian dominant, the inheritance being of an intermediate type. There is some evidence, however, that a low degree of kempiness shows partial or incomplete dominance over the varying higher degrees of kempiness. On this basis a plan is outlined for reducing the incidence of kempy fleece by selecting nonkempy breeding rams and careful culling of kempy progeny from the breeding flock.

Sheep—the development of a no-tailed breed, J. W. WILSON (*South Dakota Sta. Rpt. 1936, pp. 12, 13*).—Results are reported on the progress in the development of the no-tailed breed of sheep and the characteristics of the progeny produced in crosses of the no-tailed sheep with Southdowns.

Hair color in hunting dogs and its genetic relation to nose and iris pigment [trans. title], A. L. v. STREGER (*Zuchter*, 8 (1936), No. 10, pp. 261-271).—The author presents an analysis of color inheritance in cocker spaniels, pointers, and setters, calling attention to the genes *B* (black), *B* (extension of black pigment), and a multiple allelomorph series of intensity modifiers *W*, (*m*), (*m*), (*m*), (*m*), and (*m*). There were also factors *P* for dark eyes and black nose linked with the extension factor. The effects of combina-

tions of these factors on coat, nose, and eye color are presented. A recessive dilution factor (*Z*) was also postulated.

Siamese-Persian cats, C. E. KEELER and V. COBB (*Jour. Heredity*, 27 (1936), No. 9, pp. 339, 340, fig. 1).—Three Siamese-Persian cats were produced by mating an *F*₁ black, long-haired female, from a cross with a Persian × Siam, to her short-haired sire (*F*₁).

Further linkage data on the albino chromosome of the house-mouse, H. GRÜNEBERG (*Jour. Genet.*, 33 (1936), No. 2, pp. 255-265).—Continuing studies of linkage of the genes for shaker, albinism, and pink-eye dilution in the mouse (E. S. R., 75, p. 468), additional data brought the total number of back-cross progeny that have been produced to 3,692. An analysis of these data showed that crossing-over was less frequent in males than in females, and there were slight differences between the coupling and repulsion phases. Combination of the literature and the author's experiments gave the cross-over values for females between the genes in coupling as *sh-c* 4.43 ± 0.35 , *c-p* 17.61 ± 0.70 , and for repulsion *sh-c* 3.13 ± 0.52 , *c-p* 15.16 ± 0.77 . The cross-over values between these characters in males were 3.63 ± 0.65 , 12.04 ± 0.87 , 1.67 ± 0.68 , and 12.58 ± 0.77 in the respective classes. Age of the parents had no effect on cross-over values but evidence of interference was presented.

Grizzle, a color character of the black rat, H. W. FELDMAN (*Amer. Nat.*, 70 (1936), No. 730, pp. 502-504).—A description is given of the appearance of a character involving the appearance of white hairs interspersed with the colored ones in the pelage producing a silvering in the black rat, *Rattus rattus rattus*. The time of appearance of this character was variable, ranging from 7.1 to 17.8 mo. with an average of 14.2 mo. of age. Crosses of grizzled animals with normals produced 108 progeny, all normal, but of the 223 rats in the *F*₂s, 50 became grizzled before the age of 18 mo., suggesting that the character is recessive to the normal. The condition was variable in its extent and age of inception.

Heterogeny in the axial skeleton of the creeper fowl, I. M. LERNER (*Amer. Nat.*, 70 (1936), No. 731, pp. 595-598).—The heterogenic constituents *b* and *k* for normal and creeper fowls in the formula $y = bx^k$ expressing growth of a part in relation to the whole body are presented by the California Experiment Station. The ratio for log *b* of normals and creepers was shown to grade regularly from proximal to distal. The study was based on Landauer's data (E. S. R., 71, p. 615).

Abnormal upper mandible, a new lethal mutation in the domestic fowl, V. S. ASMUNDSON (*Jour. Heredity*, 27 (1936), No. 10, pp. 401-404, figs. 2).—An eighth lethal factor in the fowl involving abnormal maxillae of the upper mandible and associated conditions is described by the California Experiment Station. Few of the affected birds were able to pip the shell, and only one hatched. The condition appeared among the progeny of one hen, and about one-half of her normal daughters were carriers. As there was no significant departure from the normal in the sex ratio of the lethal chicks and there were produced 58 abnormalities to 173 normals, the condition is evidently due to a recessive autosomal gene. Attention is called to the occasional appearance of a similar abnormality in pheasants, partridges, and turkeys.

Endocrine weights of the Bantam fowl, S. L. LEONARD and J. W. RIGHTER (*Jour. Heredity*, 27 (1936), No. 9, pp. 363-366).—Comparison of the weights of the hypophysis, thyroids, parathyroids, adrenals, spleen, and testes of 14 adult male and 14 adult female Bantams with the weights of these organs from Leghorn fowls showed that per unit of body weight the hypophyses of the Bantams were distinctly heavier, the thyroids lighter, and the adrenals about the same

as those of the Leghorns. No sex differences were observed in the size of the endocrine glands.

Further purification of galactin, the lactogenic hormone. W. H. McSHAN and C. W. TURNER (*Soc. Expt. Biol. and Med. Proc.*, 32 (1935), No. 9, pp. 1655, 1656).—A description is given by the Missouri Experiment Station of a method by which a tenfold concentration of the lactogenic hormone from the anterior pituitary is brought about. The product brings about active proliferation of the crop gland in pigeons.

Absence of follicle-stimulating hormone in pituitaries of young pigeons. O. RIDDLE and J. P. SHOOLEY (*Soc. Expt. Biol. and Med. Proc.*, 32 (1935), No. 9, pp. 1610-1614).—The testes of immature ringdoves were increased in size 100 and 300 percent, respectively, by the implantation of one rat pituitary daily for 10 days. Adult pigeon pituitaries produced a greater response but no detectable stimulation followed the implantation of as many as three pituitaries from immature pigeons daily for 10 days. These results substantiate the indication that the slow growth of the testes of pigeons immediately after hatching is due to the failure of the pituitaries of the young pigeon to secrete any of the follicle-stimulating hormone.

Voluntary control of sex by hormone injections.—I, **Inversion of sex in the genetic male embryo** [trans. title], V. DANTCHAKOFF (*Bul. Biol. France et Belg.*, 70 (1936), No. 3, pp. 241-307, figs. 5).—Injections of folliculin into the embryos of fowls at four days of incubation were found to modify the gonads of males so that they showed female characteristics. It required about three days or more for the effects of the hormone to become evident. In general, the hormone caused proliferation of the left gonad, formation of ovarian tissue, and marked development of the oviduct on the left side as contrasted with the vas deferens on the right side.

Investigation of the treatment of fertility disorders in sheep [trans. title], J. LANGLET and M. STEFFENS (*Züchtungskunde*, 11 (1936, No. 8, pp. 312-322).—Favorable results are reported in bringing ewes which failed to breed into heat following the regular breeding season by the use of prolan, unden, and provetan, commercial preparations of the oestrus-producing hormone of the ovary. Lambs were produced by many of the ewes. Yohimbin and germinated rye were also tested.

An experiment in eutelegensis. A. WALTON and R. PRAWOCHENSKI (*Jour. Heredity*, 27 (1936), No. 9, pp. 341-344, fig. 1).—An account is given of the airmail shipment of semen collected from a Suffolk ram by the use of an artificial vagina, at the School of Agriculture, Cambridge, England, to the Jagellonian University, Kraków, Poland, where five Polish ewes were artificially inseminated. Two ewes conceived but one aborted. One lamb was born alive from semen kept alive for four days for its use in artificial insemination.

FIELD CROPS

[Field crops research in Florida] (*Florida Sta. Rpt. 1936*, pp. 36-41, 42-46, 59, 121, 122, 123, 127, 129-134, 138, 144, 146, 147, 151, 152, 156-158, fig. 1).—Agronomic investigations (E. S. R., 75, p. 615) at the station and substations, progress for which is reported as carried on by F. H. Hull, W. A. Carver, W. E. Stokes, G. E. Ritchey, W. A. Leukel, J. P. Camp, J. H. Jefferies, R. M. Barnette, J. D. Warner, A. L. Shealy, R. W. Ruprecht, A. Daane, R. E. Robertson, F. D. Stevens, T. Bregger, J. R. Neller, R. R. Kincaid, W. M. Fifield, and W. F. Ward, were concerned with breeding work with corn, oats, Napier grass, pigeonpeas, sugarcane, and peanuts; variety tests with corn, oats, grain sorghum, sorgo, sugarcane, potatoes (also seed sources), cowpeas, soybeans, alfalfa, and mis-

cellaneous forage and pasture grasses and legumes and cover crops; production tests with ramie and seed and fiber flax; fertilizer tests with corn, oats, potatoes, chufas, sugarcane, shallu, Dallis grass, and Napier grass; response of potatoes and corn to zinc; green manure studies; study of the development and deterioration of roots in relation to growth of pasture plants under different fertilizer and cutting treatments; effects of different rates and carriers of nitrogen on pasture grasses; interplanting of corn varieties with velvetbeans; rate of planting and stage of cutting tests with *Crotalaria intermedia*; relation of organic composition of crops, e. g., sugarcane, grasses, and forage legumes, to growth and maturity; composition factors affecting the value of sugarcane for forage and other purposes; physiology of the blooming of sugarcane; cultural tests with potatoes, alfalfa, corn, sugarcane, and chufas; preliminary stack silo experiments with surplus sugarcane; comparative production of silage crops, including pearl millet, sorgo, Napier grass, and Cayana sugarcane when grown at relatively high fertility levels; cutting tests with grasses; seed storage investigations; methods of producing seed in the field, germination of seed after 4 yr. in different types of storage, and plant-bed fertilization, all with tobacco; cowpeas and sorghum grown in rotations for summer cover and green manure; and crop rotation studies with corn, cotton, crotalaria, and Austrian winter peas. Pasture studies in addition to those mentioned above included effects of different fertilizer formulas on yields of pasture grasses; comparisons of native v. improved and burned v. unburned native pastures and of methods of planting centipede grass; effect of burning on growth and relative composition of range grasses; and pasture studies on peat and muck soils. Several lines of work were in cooperation with the U. S. Department of Agriculture.

[Field crops experiments at the Georgia Coastal Plain Station, 1935] (*Georgia Coastal Plain Sta. Bul.* 26 (1936), pp. 11-38, 62-64, 92-96).—Field crops work (*E. S. R.*, 75, p. 194) reviewed for 1935 and for various periods of years included variety tests with cotton, corn for yield and resistance to weevils, oats, wheat, rye, grain sorghum, sorgo, tobacco, peanuts, lespedeza, soybeans for feed and forage, cowpeas, velvetbeans, crotalaria, pasture grasses, and miscellaneous summer forage crops; breeding work with oats, peanuts, soybeans, and pasture grasses; fertilizer experiments with cotton, corn, oats, peanuts, velvetbeans, lespedeza, sweetpotatoes, and tobacco; winter cover crops for cotton and corn; and cultural (including planting) experiments with oats, wheat, peanuts, annual lespedeza and *Lespedeza sericea*, soybeans, crotalaria, and tobacco. Besides the results of fertilizer experiments with cotton and tobacco concerned with formulas, rates of applications, carriers of nitrogen, potassium, phosphorus, and placement, significant data are reported from tests of sodium nitrate and potassium for top dressing of cotton, and plant bed management studies and tests of magnesium sources and animal manures, all with tobacco. Several lines of research were in cooperation with the Georgia Experiment Station and the U. S. Department of Agriculture.

[Field crops experiments in Oklahoma, 1934-36], G. F. GRAY, E. F. BURK, J. E. WEBSTER, H. J. HARPER, H. F. MURPHY, L. L. LIGON, W. B. GERNERT, and J. C. IRELAND (*Oklahoma Sta. [Bion.] Rpt.* 1935-36, pp. 55, 56, 59, 60, 62, 68, 71, 104-117, 119, 120, figs. 5).—Experimentation with field crops (*E. S. R.*, 73, p. 32), reported on briefly for the above period, included variety tests with cotton, corn, popcorn (seed sources), grain sorghum, sorgo, potatoes, sweetpotatoes, alfalfa, lespedeza, cowpeas, soybeans, vetch and winter peas, miscellaneous grasses, and clovers; breeding work with cotton, corn, grain sorghum, sweetpotatoes, buffalo grass, and alfalfa; cultural (including planting)

experiments with cotton, grain sorghum, sorgo, winter peas and vetch, sweet-clover, and other legumes; fertilizer trials with alfalfa, vetch, and potatoes; response of alfalfa to farm manure; causes of failures of legume crops; effect of seed treatments and soil conditions on yields of fall-crop potatoes; composition of soybeans; and adaptation studies with pasture grasses and legumes.

[Field crops work in Pennsylvania], D. E. HALEY, J. J. THOMAS, C. F. NOLL, C. J. IRVIN, H. B. MUSSER, F. D. GARDNER, S. I. BECHDEL, O. OLSON, J. A. SPERRY, and M. H. KNUTSEN (*Pennsylvania Sta. Bul.* 336 (1936), pp. 4, 12, 15, 19, 20, 21, 22, 23, fig. 1).—Agronomic research reported on briefly, certain features of which were in cooperation with the U. S. Department of Agriculture, included breeding work with soybeans and tobacco; variety trials with wheat, oats, barley, soybeans, tobacco, and alfalfa; curing tests with crushed alfalfa and soybeans for hay; determination of the potassium content of tobacco; fertilizer experiments with tobacco and pasture grasses; soil acidity tolerance of red clover strains; and tobacco rotations.

[Field crops research in South Carolina], H. P. COOPER, R. L. SMITH, G. B. KILLINGER, G. M. ARMSTRONG, C. C. BENNETT, B. S. HAWKINS, N. A. SCHAPPELLE, C. H. HOLLIS, C. S. PATRICK, E. D. KYZER, J. E. LOVE, T. M. CLYBURN, J. H. MITCHELL, W. H. JENKINS, E. E. HALL, F. M. HARRELL, W. M. LUNN, H. A. MCGEE, R. W. WALLACE, N. MCKAIG, JR., W. A. CARNS, and E. W. FAIRES (*South Carolina Sta. Rpt.* 1936, pp. 19, 20, 28-33, 62, 65-69, 72-85, 93, 94-100, 107-115, 119-126, figs. 16).—Agronomic experiments (E. S. R., 75, p. 37), reported on briefly from the station and substations (in certain lines in cooperation with the U. S. Department of Agriculture), included variety tests with cotton, corn, oats, wheat, soybeans, crotalaria, and miscellaneous pasture grasses and legumes; breeding work and genetic studies with cotton; hybridization experiments with sea-island cotton; fertilizer and nutrition studies with cotton comprising placement, time and rate of applying potassium fertilizers, trials of nitrogen carriers for side dressing; yields of seed cotton from use of calcium nitrate v. sodium nitrate and sodium chloride v. potassium chloride; tests of brands of sodium nitrate; the effect of magnesium in the mineral nutrition of the cotton plant; yields of seed cotton from the use of acid and nonacid fertilizers; effect of additions of sodium in the fertilizer on the yields of cotton; residual effects of potash on cotton; effects of winter legume cover crops on cotton following, with and without sodium nitrate applications, and manure v. green manure; seed treatments, and studies of variation in fiber length, fineness, and maturity in several cotton varieties; tobacco investigations, including trials of fertilizer mixtures and placement, fertilization of plant beds, effects of natural weed fallow of several common weeds on yield and quality, study of effects of fertilizers high and low in sulfur, and fertilizer formulas again recommended for bright flue-cured tobacco and plant beds; a spacing test with cotton; adaptation and propagation of pasture grasses; fertilization of carpet grass pasture and reestablishment of lespedeza in the sod; effects of superphosphate, basic slag, and potash on the growth and mineral content of carpet grass; and a grazing experiment to determine the combination of annual crops to provide pasture throughout the year for dairy cows in milk.

[Agronomic research in South Dakota], A. N. HUME and N. E. HANSEN (*South Dakota Sta. Rpt.* 1936, pp. 9, 10, 32, 33).—Field crops investigations (E. S. R., 75, p. 617), including breeding work with corn, spring and winter wheats, and barley; crop rotations for bindweed control; and tests of perennial wheat are reviewed briefly.

[Field crops research in Utah], R. J. EVANS, R. W. WOODWARD, D. C. TINGEY, D. W. PITTMAN, J. W. CARLSON, G. WHORNEAM, A. F. BRACKEN, J. E. GREAVES, R. J. BECRAFT, L. A. STODDART, and B. MAGUIRE (*Utah Sta. Bul.* 276 (1936), pp. 1-6, 33, 34, 46-48, 63-68, figs. 9).—Further progress is reported from agronomic experiments (E. S. R., 72, p. 316) at the station and substations for the biennium ended June 30, 1936, comprising variety tests with spring and winter wheat, oats, corn, alfalfa, soybeans, and miscellaneous forage grasses; breeding work with barley, wheat, and alfalfa; cultural tests with sugar beets and soybeans; seed production studies with alfalfa (E. S. R., 74, p. 478; 75, p. 333); comparative tests of leading varieties of barley, wheat, oats, and corn for livestock feed (E. S. R., 74, p. 626); wheat experiments on dry land concerned with varieties, tillage, and cultural practices, type of plowing, manuring and green manuring, stubble burning, cropping systems, and nutritive value (high v. low calcium and phosphorus content) and mineral content of different wheat varieties; range investigations, including collection of range plant species and maintenance of the Intermountain Herbarium, adaptation studies, tests of fall, winter, and spring cuttings of native species for erosion control, and observation on depreciation of ranges by excessive grazing and water and wind erosion; and studies dealing with losses due to weeds, manure as a carrier of weed seed (E. S. R., 71, p. 773), longevity of weed seeds, and tillage and other weed control measures. Certain phases of the research were in cooperation with the U. S. Department of Agriculture.

[Agronomic experiments in Wyoming] (*Wyoming Sta. Rpt.* 1936, pp. 3, 4, 18-21, 22, 23, 24-26, 27, 28, 29).—Experiments with field crops (E. S. R., 75, p. 38) at the station and substations, for which progress results are reported, included variety tests with winter and spring wheat, oats, barley, corn, potatoes, alfalfa, and miscellaneous forage grasses and mixtures; cultural (including planting) experiments with winter and spring wheat, barley, oats, corn, crested wheatgrass, brome grass, and alfalfa; fertilizer trials with alfalfa and sugar beets; a test of barley as a nurse crop for alfalfa; crop rotations and methods of preparing seedbeds; effects of a shelter belt on increasing crop yields inside of the protected areas; an irrigation test with Jerusalem-artichokes; pasture studies; and control of whitetop and Canada thistles. A number of lines of work were in cooperation with the U. S. Department of Agriculture.

[The progress of field crops work at Wyoming State experiment farms] (*Wyoming Sta. Bul.* 219 (1937), pp. 5-16, 19, 20, 22-24, 27-33, 34-36, 37-39, 40-43, 44, 45, fig. 1).—Progress results are reported from agronomic activities on the experiment farms near Cheyenne, Eden, Gillette, Afton, Lander, Lyman, Sheridan, Torrington, and Worland, including variety tests with oats, barley, wheat, corn, alfalfa for yield and wilt resistance, soybeans, sugar beets, and annual forage crops and grasses; trials of pasture grasses and mixtures; comparisons of certified potato seed grown for 1 and 2 yr. under irrigation; cultural (including planting) tests with corn, winter wheat, spring wheat, oats and barley, alfalfa, potatoes, and sugar beets; fertilizer trials with oats, alfalfa, potatoes, and sugar beets; effect of manure on nonirrigated crops of corn, potatoes, beans, spring wheat and alfalfa; crop rotations; the effect of tillage on crop yields in a rotation including corn, spring wheat, and oats; renovation of permanent pastures and alfalfa fields; and the control of quackgrass and whitetop. Several lines of work were in cooperation with the U. S. Department of Agriculture.

Grassland management, D. S. FINK (*Maine Sta. Bul.* 384 (1936), pp. 402-405, fig. 1).—The response of permanent pasture to various fertilizer combinations and lime and of timothy meadows to fertilizers is reported on briefly.

The effect of exposure in the field on grade, strength, and color of raw cotton, M. A. GRIMES (*Texas Sta. Bul. 533 (1936), pp. 35, figs. 17*).—Ferguson Triumph 406 cotton grown in 1931 and 1932 at Temple, Chillicothe, and Lubbock, was picked after opening and after intervals of exposure ranging from 1 to 33 weeks; and after ginning, and classing (by J. G. Powers), strength determinations, and color analyses were made.

A drop of one grade had occurred after 1 week of exposure at one station and after an average of less than 4 weeks for all stations and seasons. A drop of 4 and 5 grades, a decrease of from $\frac{1}{16}$ to $\frac{3}{16}$ in. in length, and a decrease in price of from 150 to 265 points occurred during exposure. The loss due to exposure was in some cases nearly one-half the price of unexposed cotton, or at 1932 and 1933 prices about \$13 per 500-lb. bale.

All of the cotton lost strength, but not equally, upon exposure. There was an average loss of 4 percent after 4 weeks and a maximum loss of approximately 14 percent for the season. Cotton grown at Temple lost the lowest and that grown at Lubbock the highest percentage of the original strength. These differences were not attributed entirely to differences in rainfall but might have been due partly to greater ultraviolet in the sunlight at the higher altitude. Regional and seasonal differences were noted in the color. All cottons became darker and less creamy as the exposure increased. In all cases there was a decrease in either creaminess or brightness, or in both, within from 3 to 5 weeks after opening. Cotton which had opened after frost was stained and much yellower than that opened before frost. Precipitation apparently caused greater darkening than it did loss in creaminess. The grades appeared to follow brightness more closely than creaminess.

Three lots of lint cotton stored in a vault for 1 yr. had lost respectively 7, 15, and 18 percent of their original strength, and after 2 yr. of storage two lots had lost 25 and 33 percent.

Conclusions were that cotton should be harvested, so far as is practicable, not later than 4 or 5 weeks and preferably within 1 or 2 weeks after opening to assure a product of high quality in grade, strength, and color.

Influence of storage temperature and humidity on seed value of potatoes, O. SMITH (*[New York] Cornell Sta. Bul. 663 (1937), pp. 31, figs. 14*).—Field studies made, 1932–35, to determine effects of various methods of storing seed potatoes on subsequent plant growth and yield involved the Irish Cobbler and Smooth Rural varieties. Comparisons were made between storage in five commercial potato-storage houses and at various locations within each storage. Seed also was stored in constant-temperature cold-storage rooms during the entire storage period at both high and low humidities. Temperature shifts also were made for other treatments from 5 to 8 weeks before planting.

Low humidity in storage was found to result in the least sprouts per seed piece but in the longest individual sprouts. The most sprouts appeared on tubers stored at 40° F. and later shifted to 50°, but they were rather short. The final stand of plants usually was lower from seed stored at 32° than from that stored at higher temperatures. Differences in the rate of emergence of plants were not so marked as expected from differences in average storage-season temperatures and humidities between the several commercial storages. This seemed due primarily to the fact that unless the tubers are removed from storage and planted early, the temperature in all storages for the last month or two exceeds sprouting temperature. Plants from tubers stored in constant-temperature cold-storage rooms appeared above ground in the order 50°, 40°, 35°, and 32°. The most stems per seed piece, the largest total number of tubers per plant, and the most U. S. No. 1 size

tubers were produced by tubers stored at the higher temperatures. Storage treatments which produced plants above ground first did not always result in highest yields of tubers. Plants from tubers stored at any treatment with an initial temperature of 50° matured about 7 to 10 days earlier than those stored at 40°.

The two varieties responded differently in yields of tubers to the same storage conditions. The highest yields of Irish Cobbler usually were obtained from storage at 40° for all or part of the storage period, whereas highest yields of Smooth Rural resulted from storage at 50° for part or all of the storage period. Sprout growth with Irish Cobbler, it seemed, becomes too extensive for maximum yields when stored at 50°, whereas with Smooth Rural sprout growth is slower and reaches optimum at 50° or slightly lower.

"In localities where early planting usually results in highest yields it would be desirable to store seed at the higher temperatures so that sprout growth at planting time would be as large as possible without having them damaged or broken off in the cutting and planting operations. Where later plantings usually result in highest yields, any treatment which suppresses sprout growth, such as low temperatures, will result in increased yields unless planting is delayed too long."

Effect of soil reaction on growth, yield, and market quality of potatoes, O. SMITH ([*New York*] *Cornell Sta. Bul.* 664 (1937), pp. 21, figs. 16).—Smooth Rural potatoes were grown, 1932-36, on 30 plats of varying degrees of soil reaction. The original reaction, from pH 5.4 to 5.7, was adjusted by the use of sulfuric acid and hydrated lime so that a range in soil reaction of about from pH 4.75 to 8 was maintained after the first year.

Vine growth was less vigorous and the foliage lighter green on soil that was too acid or too alkaline as compared with plants on soil with favorable reaction. Early death of the plants was another indication of too-acid or too-alkaline soil. Rate of emergence was slower in the most alkaline plats, whereas in the most acid plats it was slow in the first and second years but fastest during the third year after the sulfuric acid was applied. The final stand of plants and the number of stems per plant were not influenced by soil reaction within the experimental range.

The soil reactions more acid than pH 4.8 resulted in reduction of number of tubers per plant. At the higher pH values a marked reduction occurred in the number of No. 1 and in total number of tubers per plant. Plants on the most alkaline soils produced a lower percentage of and smaller No. 1 tubers than those on less alkaline or on acid soils. Yields were reduced on soils more acid than about pH 4.8. In general, no significant differences in total yield existed between plats with reactions of approximately from pH 4.8 to 7.1, but significant yield decreases occurred in plats with soil reaction exceeding about from pH 7 to 7.5.

With the scabby tubers removed, the highest percentage of U. S. No. 1 grade potatoes came from the most acid and most alkaline soils and the lowest percentage from soils between pH 6 and 7, sometimes as high as pH 7.8. A gradual increase occurred in the percentage of scabby tubers from the most acid plats up to those with the reactions pH 6.51 to 6.58 in 1932, pH 7.8 to 7.95 in 1933, pH 6.94 to 7.53 in 1934, pH 7.24 to 7.37 in 1935, and pH 6.71 to 6.76 in 1936. In soils with reactions above these the percentage of scabby tubers always was reduced markedly.

The Houma potato: A new variety, O. F. CLARK, F. J. STEVENSON, and J. C. MILLER (*U. S. Dept. Agr. Circ.* 420 (1936), pp. 4, fig. 1).—The Houma potato, derived from Charles Downing × Katahdin (*E. S. R.*, 74, p. 630), is described from studies in cooperation with the Louisiana and other experiment

stations as a vigorous-growing, late-maturing variety that produces smooth, nearly round tubers, slightly flattened at the apex, with shallow eyes, dark buff in color, and high in cooking quality. In a number of tests it compared favorably in total yield with Katahdin, Chippewa, Irish Cobbler, and Green Mountain. It appeared to be well adapted to Maine, North Carolina, and particularly to Louisiana where its many desirable characteristics led it to be considered of much promise.

HORTICULTURE

[Horticultural investigations by the Florida Station] (*Florida Sta. Rpt. 1936*, pp. 41, 42, 58, 59, 61, 73-79, 80-82, 110-113, 118-122, 140, 148-151, 152, 153, figs. 5).—Among studies, the progress of which is discussed, are the breeding and testing of new sweet corns, by F. H. Hull and W. A. Carver; potash requirements and effects on citrus and concentrated and other fertilizers for citrus, both by R. W. Ruprecht; soil and fertilizer needs of celery, by E. R. Purvis and Ruprecht; variety response of pecans to different soil types, cover crops for pecans, effect of zinc sulfate on pecan rosette, fertilizer requirements of the pecan, and the extraction of oil from kernels of different varieties, all by G. H. Blackmon; propagation, breeding, and fertilizing tests with tung oil trees, by A. F. Camp and R. D. Dickey; variety-testing and propagation of ornamentals, by Camp and Blackmon; variety trials with truck crops, soil pH needs of truck crops, and cover crops for vegetable culture, all by F. S. Jamison; comparison of mulch, clean culture, and no cultivation for citrus, by Camp; relation of nitrogen absorption to food storage and growth in the pecan, by Blackmon and Camp; variety tests of blackberries, by Camp and H. S. Wolfe; preservation of citrus juices and pulps, strawberries, and Youngberries, by Camp and A. L. Stahl; maturity studies with citrus, by Stahl; and effects of zinc and other unusual minerals on citrus, by Camp.

Studies at the Citrus Substation include citrus progeny and bud selection, propagation experiments with citrus, testing of new varieties and hybrids of citrus and near citrus, and rootstock trials with citrus, all by J. H. Jefferies.

Studies reported by the Everglades Substation include rootstocks for grapefruit, trials of *Casuarina lepidophloea* for pulp and firewood, forcing of Easter lily by low temperature treatment, and pollination and seed setting in the Easter lily, all by G. R. Townsend and R. N. Lobdell; fertilizer requirements of celery, cabbage, and other vegetables, by A. Daane, R. E. Robertson, and F. D. Stevens; and miscellaneous variety tests of vegetables, by Townsend.

Studies at the Subtropical Substation include tests of various windbreak and forest species, trials of minor fruits and ornamentals, culture of the avocado, and culture of citrus, all by H. S. Wolfe; culture and breeding of the tomato, and variety tests of miscellaneous vegetables, all by W. M. Fifield.

[Horticultural investigations at the Georgia Coastal Plain Station] (*Georgia Sta. Bul. 26* (1936), pp. 66-74, 76-90, 102-106, fig. 1).—Included are reports on variety, cultural, and fertilizer studies with tomatoes, watermelons, lima beans, and other vegetables, development of wilt-resistant watermelons and root-rot-resistant beans, variety tests of various tree fruits, grapes, and pecans, improvement of the blueberry by plant selection, and varietal and adaptation tests with citrus fruits and tung oil.

[Horticultural investigations conducted by the Maine Station] (*Maine Sta. Bul. 384* (1936), pp. 389-391, 401, 423, 430, fig. 1).—Studies, the progress of which is discussed, include nature of winter injury to the apple and the comparative resistance of different apple rootstocks to low temperature, both by M. T. Hilborn; boron requirements of rutabagas, by F. B. Chandler, J. A.

Chucka, and I. C. Mason; and burning of blueberry fields and the control of weeds therein, by Chandler and Mason.

[Horticultural investigations at the Oklahoma Station], F. B. CROSS, G. F. GRAY, E. F. BURK, I. C. HAUT, J. E. WEBSTER, and [G. W.] COCHRAN (*Oklahoma Sta. [Bien.] Rpt. 1935-36, pp. 43-55, 56-59, 60-62, 63, 71-73*).—Among studies discussed are those dealing with soil management of pecan groves, varieties and propagation of pecans, development of vineyards, grape varieties, uneven color development in the Concord grape, small fruit varieties, soil management in apple and peach orchards, varieties of apples, peaches, and plums, variety tests of vegetables, culture of asparagus and broccoli, varieties of cantaloups, development of a spineless okra, greenhouse tomato culture, effect of fertilizers on the shipping qualities of strawberries and tomatoes, use of synthetic manures in heating hotbeds, and the influence of variety on the composition of grape juices.

[Horticultural investigations by the Pennsylvania Station] (*Pennsylvania Sta. Bul. 336 (1936), pp. 5, 27, 32-34, 35*).—Brief results are presented on studies of synthetic composts for mushrooms, by J. W. Sindén; improvement of winter cabbage and of the Penn State tomato, by C. E. Myers and M. T. Lewis; fertilizers for truck crops on Hagerstown soils, by W. B. Mack; head lettuce breeding, by Lewis; breeding of inbred strains of sweet corn, by Myers and Lewis; asexually propagated rootstocks of cherry, by R. D. Anthony; new varieties of apples, by R. H. Sudds; new ornamental shrubs, by R. P. Meahl; cabbage variety and strain trials and pea variety trials, both by Mack and F. W. Haller; sweet corn and tomato variety and strain trials, by Mack, G. J. Stout, and Haller; and variety trials of celery, lettuce, onions, and spinach, by Mack.

[Horticultural investigations by the South Carolina Station] (*South Carolina Sta. Rpt. 1936, pp. 23-28, 100-106, 130-136, figs. 3*).—Included are reports on the following projects: Factors associated with the fruiting of the Fordhook bush lima bean, and variety trials of vegetables, both by F. S. Andrews; organic food reserves in the asparagus crown, fertilizer requirements of asparagus, time of cutting asparagus, and the testing of peach and grape varieties, all by L. E. Scott; fertilizer requirements of beans and cabbage, variety tests of lima beans, tomatoes, peas, and other vegetables; production of snap bean seed, effects of basic slag and dolomitic limestone on snap beans, and cabbage breeding, all by J. M. Jenkins, Jr.

[Horticultural investigations at the South Dakota Station], N. E. HANSEN (*South Dakota Sta. Rpt. 1936, pp. 29-32, 33*).—Brief reports are presented on apricot breeding, apple breeding, testing of Siberian crabs as rootstocks, testing of new Siberian bird cherries, breeding of roses, development of thornless rose stocks, tomato breeding, improvement of the sand cherry, and iris breeding.

Orchard and garden crops (*Utah Sta. Bul. 276 (1936), pp. 55-62, figs. 6*).—Included are general progress statements on rootstock studies with cherries and apricots, embryo abortion in the sweet cherry, nomenclature of apricot varieties, desirable varieties of sweet and sour cherries, peaches, and plums for Utah, all by F. M. Coe; and storage of onions, the improvement of the sweet Spanish onion by selection, spacing of onions, and use of electricity for heating hotbeds, all by A. L. Wilson.

[Horticultural studies at the Wyoming State experiment farms] (*Wyoming Sta. Bul. 219 (1937), pp. 17-19, 21, 22, 25, 39, 43, fig. 1*).—Included are brief reports of studies of species for shelterbelt uses, the value of irrigation for vegetables, improvement of the apple by development and selection of seed.

lings, varietal tests of vegetables and fruits, time of planting vegetables, and improvement of the garden bean by selection of desirable plants.

Available nutrients in lawn, garden, and greenhouse soils. F. F. WEINARD (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), p. 654).—A tabulated summary is presented of the results of tests for soil reaction, available nitrogen, phosphorus, and replaceable potassium in soil samples collected by the Illinois Experiment Station from 57 lawns, 35 gardens, and 51 floricultural greenhouses. The pH ranges found in the lawns, gardens, and greenhouses were, respectively, 5.6 to 8.2, 4.7 to 8.2, and 4 to 8.3.

Supplementary illumination from Mazda, mercury and neon lamps on some greenhouse plants. G. H. POESCH (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 637, 638).—Normal light and normal light plus 4 hr. of supplementary light from (1) two 225-w clear glass Mazda lamps, (2) 450 w of neon lamps, and (3) 450 w from mercury vapor lamps, were compared at the Ohio State University for pansies, chrysanthemums, and other ornamentals. In every case the plants under Mazda lamps had longer stems but the quality of the flowers was not reduced. The color of the foliage was paler under supplementary light. The records showed that the Mazda lamps were superior to both neon and mercury in promoting earliness of bloom, total production, and stem length.

A further trial of ring grafting to produce stock effects. R. H. ROBERTS (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 358, 359).—Additional data presented by the Wisconsin Experiment Station (E. S. R., 73, p. 614) showed that certain combinations of stem and bark gave somewhat different results in 1935 than in 1934, apparently because of seasonal influences. When rings of bark were inverted from the normal position the tops were dwarfed, with dark green leaves, slender shoots, and a delayed accumulation of starch.

Analyses of materials sold as insecticides and fungicides during 1936. C. S. CATHCART and R. L. WILLIS (*New Jersey Stat. Bul.* 617 (1936), pp. 16).—This bulletin presents in the usual manner (E. S. R., 74, p. 338) the results obtained from the inspection of 1936.

Some factors associated with dormancy of lettuce seed. R. C. THOMPSON (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 610-616).—Seeking an explanation of the occurrence and development of dormancy in lettuce seed, the author, working at the Horticultural Research Station, Beltsville, Md., made germination tests of seed from individual plants of 25 varieties. He observed not only wide variation between varieties but between individual plants in a single variety. Of all the varieties tested, Hubbard Market exhibited dormancy most consistently and Iceberg was by far the freest. Grand Rapids and Iceberg seeds harvested in a fully mature condition developed more readily than seeds harvested when well developed but with peduncles still green. Where Grand Rapids seed was harvested in three stages, (1) fully mature, (2) with yellow involucre, and (3) with green involucre, good results were obtained in both light and darkness in the first instance, good results were secured with light treatment in the second case, and little germination with any treatment in the third instance. Lot 2 exhibited the characteristics of dormant seed, all of which leads the author to suggest that inadequate nutrition may be concerned in dormancy in lettuce. The fact that light seed producing varieties such as Iceberg are freer from dormancy than the heavy seed producers suggests also a relationship with nutrition. Under heavy seed producing conditions, lack of adequate nutrients may prevent the development of the embryos to a stage permitting germination immediately following harvest.

Effect of fertilizer on quality and chemical composition of canning peas. F. L. MUSBACH and O. E. SELL (*Jour. Agr. Res. [U. S.]*, 53 (1936), No. 11, pp. 869-879).—Studies conducted by the Wisconsin Experiment Station with Per-

fection peas grown on Colby silt loam and Advancer peas on Miami silt loam indicated, in general, that well-balanced complete fertilizers increased yields and improved the quality of the canned product. Analyses of the seed coats of peas from the Colby soil revealed a general trend, irrespective of fertilizer treatment, toward a consistent decrease in the percentage of nitrogen content with advancing maturity, assuming that the larger peas are the more mature. Phosphorus content of the skins showed the same general trend as nitrogen, but no definite relationship was noted between potassium content and maturity or with the potassium content of the fertilizer used. A relationship was established between the calcium content of pea skins and the potassium content of the fertilizers. In general, potassium in the fertilizer tended to diminish the concentration of calcium in the seed coat. In fact, all the fertilizer treatments reduced the calcium concentration in the seed coat. No definite relation was established between calcium in the seed coat and the quality of the canned product.

The chemical composition of whole peas included studies of sugar and starch. Variations in quality of the canned product could not be explained by differences in the sugar and starch content of fresh peas, leading to the conclusion that variations in quality of peas harvested at relatively early stages of maturity are due to variations in organic compounds other than sugar and starch.

Chemical studies on the open-pollinated, top-cross, and hybrid inbred strains of yellow sweet corn in relation to the quality of the canned product, R. R. JENKINS and C. B. SAYRE (*Food Res.*, 1 (1936), No. 2, pp. 199-216, figs. 3).—Records taken by the New York State Experiment Station showed that hybrid strains of sweet corn are superior to open-pollinated varieties from the standpoint of increased quality, slower rate of increase in maturing of ears, and a much longer harvest spread due to a slower increase in total solids and of alcohol-insoluble solids. It was observed that the percentages of total solids and of alcohol-insoluble solids may serve equally well as indices of maturity and of quality in canned whole-grain sweet corn of the types studied. The percentages of total solids and of alcohol-insoluble solids were lower in the canned than in fresh corn.

Some results of horticultural experimentation at Mountain Grove, P. H. SHEPARD (*Missouri State Hort. Soc. Proc.*, 1933-34, pp. 69-75).—Among studies discussed in this brief report are variety tests of new fruits, the development of winter-resistant apple trees by double working on a hardy interstock, the value of potassium permanganate for stimulating callus and root development in grape cuttings, the growing of vinifera grapes, height of heading young apple trees, and a comparison of mulch and tillage for apple trees. Trees under the straw mulch system responded very favorably in growth, survival, and productivity.

Tree fruit varieties in north Texas, L. E. BROOKS (*Texas Sta. Bul.* 535 (1936), pp. 26, figs. 3).—Varietal investigations begun at the Wichita Valley substation in 1926 have shown that apples and pears are unsatisfactory in this area because of their susceptibility to cotton root rot. Cherries proved unsuitable, dying generally from natural causes without reaching fruiting age. Peaches and plums proved to be the most dependable tree fruits for the area, and the Moorpark apricot gave promise of being a valuable variety. In the case of peaches and plums varietal selection was an important feature, with resistance to late spring freezes a most important characteristic. A few peaches and plums fruited in six or seven years. The Dr. Burton peach proved outstanding in yield and consistency of fruiting.

A simple method of obtaining fruit trees on their own roots, W. L. KERR (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 355-357, fig. 1).—At the Dominion Experimental Station at Morden, Manitoba, apple scions grafted into the basal

rather than the customary apical end of the stock produced roots above the union rather freely, thus permitting the ready development of own-rooted trees. There was apparently an accumulation of nutrients above the point of the union, resulting in scion root development. The stock, on the other hand, was stunted, produced no rootlets, and was easily separated from the scion.

Some observations on the production of own-rooted apple stocks from root cuttings, V. T. STOUTEMYER, T. J. MANEY, and B. S. PICKETT (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 350-354, figs. 3).—Using a heated closed propagating frame in the greenhouse of the Iowa Experiment Station, 6-in. root pieces of Virginia crab, laid horizontally on the surface of moist sand, formed an abundance of shoots. Similar results were secured with root cuttings of *Malus sargentii* and *M. baccata*. The best results were secured when roots were taken from dormant trees. Two lots of softwood cuttings taken from the sprouts of Virginia crab when placed in an open propagating bench rooted abundantly. The original root pieces produced a moderate second crop of shoots. The plants grown from the softwood cuttings developed much more satisfactorily than did those from shoots with a piece of the original root still attached. Apparently the presence of the root piece and its fibrous roots prevented the ready development of new roots on the young shoot.

The influence of water deficiency in photosynthesis and transpiration of apple leaves, A. J. HEINICKE and N. F. CHILDEES (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 155-159).—Observations at Cornell University on leaves of McIntosh, Baldwin, and Delicious apple trees, growing in the greenhouse in containers supplied with different amounts of water, showed that gradual drying of the soil is accompanied by an appreciable reduction in the rates of transpiration and photosynthesis. Both the dry and control plants frequently showed a greater assimilation in the morning than in the afternoon and, in general, transpiration showed the same tendencies as the carbon dioxide assimilation. However, drying of the soil affected transpiration somewhat sooner than it did photosynthesis, apparently because of the closing of the stomata, which tended to conserve water to a greater extent than it reduced photosynthesis.

The "graduated space" method of thinning apples, H. P. GASTON and G. L. RICKS (*Michigan Sta. Spec. Bul.* 281 (1937), pp. 30, figs. 7).—Following an earlier paper (*Ill. S. R.*, 74, p. 642) in which it was shown that the natural tendency of weak slender branches is to produce small apples and that in pruning it is desirable to remove such growths instead of the thicker and more vigorous wood, the authors discuss fruit-thinning experiments in eight representative Michigan orchards including several varieties of apples. Graduated-space thinning in which fruits were spaced according to the diameter of the branch was compared with uniform-distance thinning and with no thinning. Both types of thinning reduced total yields, graduated-space thinning about 10 percent and uniform thinning about 17 percent. Graduated- and uniform-space thinning reduced the percentage of apples less than 2.25 in. in diameter by 84 and 56 percent, respectively. At the same time, fruits 2.5 in. or more in diameter were increased by 99 and 56 percent, respectively, over the nouthinned trees. Color grade was also improved by thinning. Of major significance was the fact that graduated-space thinning yielded sufficient increments in sale value to yield a substantial profit for the thinning operations. The practice of graduated-space thinning is explained in detail.

Repairing injured apple trees, C. W. ELLENWOOD and T. E. FOWLER (*Ohio Sta. Bimo. Bul.* 184 (1937), pp. 27-32, figs. 3).—Stating that the low temperatures of the 1935-36 winter caused severe injury to the trunks and crotches of apple trees, the authors present information on the treatment of injured trees and on the nature of the injuries. Among points considered are wound dress-

ings, bridge grafting, cleansing and filling of cavities, and the bracing of weakened limbs.

Prevention of storage wastage in Cox's Orange Pippin apples: Results of cold-storage investigations, R. SUTHERLAND (*New Zeal. Jour. Agr.*, 53 (1936), No. 1, pp. 12-19, figs. 6).—Cox Orange Pippin apples grown on sandy loams were found less susceptible to bitter pit and internal break-down than comparable apples from clay soils. Maturity was a factor in the incidence of bitter pit, the disease becoming progressively less as harvesting was delayed, but susceptibility to internal break-down and fungal rotting increased. Internal break-down was less in fruit stored at 37° F. than at 34°. Mature, ripe apples were more easily bruised in packing than less mature fruits.

Production of cherry seedlings from freshly harvested seed [trans. title], R. VON VEH (*Züchter*, 8 (1936), No. 12, pp. 305-312, figs. 16).—In this succeeding paper (*E. S. R.*, 75, p. 781), the author discusses the production of seedlings from embryos extracted from freshly harvested cherry seeds of several different varieties. The flotation method proved satisfactory in separating potentially viable and nonviable seeds, those with well developed embryos sinking usually to the bottom. Water was apparently a very important factor in determining the early development of cherry seeds. While surrounded by the nucellus the water-assimilation capacity of the embryo was distinctly hindered.

A relation between seed attachment and carpel symmetry and development in Prunus, H. B. TURKEY (*Science*, 84 (1936), No. 2188, pp. 513-515, fig. 1).—In examinations at the New York State Experiment Station of 24 varieties of peach, plum, cherry, apricot, and nectarine, it was observed that in cases of asymmetric fruits the seed is attached to the larger and better developed side of the carpel. Apparently in the case of a simple fruit the position of the embryo in relation to the carpel and its point of attachment to that carpel affects markedly the shape and development of a portion of the fruit.

Results of mulching black raspberries, L. HAVIS (*Ohio Sta. Bimo. Bul.* 184 (1937), pp. 18-20).—Cumberland raspberries planted in 1928 and mulched in March 1935 with wheat straw at the rate of 5 to 6 tons per acre were superior in vigor and general appearance to adjacent comparable cultivated plants. Soil nitrates were usually lower in the mulched plats during the spring and summer, but average moisture content was higher and more uniform. In 1936, the number of new canes produced was definitely higher in the mulched areas. Yields were somewhat larger on the mulched plats, but the experiment was terminated before final conclusions could be drawn.

Leaf-bud propagation of several introduced species of Rubus, C. C. THOMAS (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 377-379).—The following forms of *Rubus* were rooted successfully in a comparatively short period from leaf-bud cuttings placed in clean sharp sand in a heated propagation frame: *R. armeniaca*, *R. ellipticus*, *R. fraxinifolia*, *R. glaucus*, *R. parvifolia*, and *R. leucodermis*, the Brainerd blackberry, and the Van Fleet raspberry. All of these forms root from the tips of canes, indicating a correlation between cane tipping habit and capacity to propagate by leaf cuttings.

Harvesting and handling citrus fruits in the Gulf States, J. R. WINSTON (*U. S. Dept. Agr., Farmers' Bul.* 1763 (1937), pp. 11-38, figs. 20).—Superseding Farmers' Bulletin 696 (*E. S. R.*, 34, p. 235), this presents general information on harvesting operations, management of the packing house, control of diseases in harvested fruits, grading, packing, precooling, transportation, etc.

Bud selection in Eureka and Lisbon lemons and progeny tests of bud variations, A. D. SHAMEL, C. S. POMEROY, and R. E. CARYL (*U. S. Dept. Agr.*,

Tech. Bul. 531 (1936), pp. 44, figs. 25).—In this further contribution to the general subject (E. S. R., 43, p. 440), the authors describe and depict some of the more important variations occurring in the two varieties and present in tabular form the performance records taken over a long period of years on the progeny of different strains. Three types of variation were distinguished, (1) those occurring as limbs on otherwise normal trees, (2) as entire trees differing in one or more well-defined characters, and (3) individual fruit variations. The progenies of the limb and entire tree variations performed like their parents with respect to yield, growth, time of year in which they bore most of their fruit, shape and size of fruit, texture and thickness of the rind, juiciness, and acidity of the juice. The results indicate that bud selection based on performance records permits, through the choice of buds from superior trees or limbs, the isolation of commercially superior varieties of Eureka and Lisbon lemons.

Regeneration of date palm roots, R. H. PEEBLES (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), p. 376, fig. 1).—Observations in Arizona showed that date roots had regenerated new root tips when examined 97 days after excision. New growth was vigorous and approximated in diameter that of the older portion.

Miscellaneous plants under cloth enclosure, D. FOOTE and A. LAURIE (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 642-644).—Observations are presented on the results of studies at the Ohio State University on the growing of roses, hydrangeas, chrysanthemums, gardenias, kalanchoe, and stocks in cloth-covered enclosures such as used for China asters. In all cases favorable responses were secured from the cloth cover.

Growth responses of some ornamental plants to temperature, K. POST (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 647, 648).—Providing two temperature environments, namely, 50° to 60° F. and 60° +, it was found at the [New York] Cornell Experiment Station that the following ornamentals may be grouped roughly according to their response to temperature as follows: (1) Those which grew very little below 60°, *Hunneemannia* and *Brodiaea*, (2) those which grew but did not flower below 60°, *Trachymene* and *Olarkia*, and (3) those which grew above 60° but required lower temperature to form flower buds, *Mathiola* and *Cytisus*.

Flowering response to temperature in China aster, J. P. BIEBEL, L. GREENE, and R. B. WITTEBOW (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 645, 646).—Studies at the Indiana Experiment Station of the effect of variations in temperature on the photoperiodic response of the Heart of France variety of China aster indicate that higher temperature may affect greatly not only the time of blooming in the aster and the character of the inflorescence produced but may induce flowering despite unfavorable length of day. The authors point out that the aster responds differently from the stock, wallflower, beet, cabbage, and celery, where high temperatures tend to inhibit flowering. Under the short days of late autumn and early winter, the stems were shorter and the flowers were somewhat smaller but had good form and color.

Reduction of daylight period on asters, A. LAURIE and D. FOOTE (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 639-641).—Further information (E. S. R., 75, p. 349) is presented on the results of photoperiodic studies with garden asters. Reduction of daylight induced earliness in all seven varieties, but in Royal Shell Pink the flowers produced were on such short stems as to be of little economic value. In most cases reduced light resulted in slightly smaller flowers. Supplemental light used on seedlings for two weeks prior to transplanting out of doors had no marked effect on subsequent behavior.

Some studies on the forcing of Delphinium, H. E. WHITE (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 653, 654).—At the Massachusetts Experiment Station field-grown plants held for eight weeks, beginning August 17, in cold storage at 34° to 36° F., and planted October 24 in a greenhouse came into bloom on December 24, whereas comparable untreated plants made no growth at all. Potted plants placed in cold storage on July 15 and planted September 14 commenced blooming November 1. On the whole, however, field-grown plants gave better results than potted plants.

Some effects of temperature and light upon the flower bud formation and leaf character of stocks (*Mathiola incana*), K. POSE (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 649-652).—In this further contribution (E. S. R., 75, p. 351) the author presents evidence of the profound influence of temperature on the flowering and growing habits of the garden stock. For example, plants grown at temperatures above 60° F. at night and at lower temperatures during the day produced pinnately lobed leaves and flowered, while plants held below 60° during the night and above 60° during the day produced entire to sinuate leaves and no flowers.

Abscission of sweet pea flower buds, J. E. SMITH (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 663-668, figs. 2).—At the Indiana Experiment Station normal and dropping sweet pea buds collected at various stages of development were examined microscopically. After discussing the general anatomy of the sweet pea bud and the formation of the abscission layer, the author points out that the most marked difference between the developing and dropping bud is a drying out of the flower parts of the latter. Apparently bud drop results from the desiccation and degeneration of flower parts caused by an upset in the carbohydrate-nitrogen balance during periods of cloudy weather.

Our friends the trees, P. G. CROSS (*New York: H. P. Dutton & Co., 1936, pp. 334, [pls. 31, figs. 52]*).—General information is presented on economic importance, botanical relationships, planting, culture, utilization, etc.

FORESTRY

Forestry and permanent prosperity, R. F. HAMMATT (*U. S. Dept. Agr., Misc. Pub. 247* (1936), pp. 20, figs. 29).—Among subject matter covered in this general discussion is material relating to forestry as an aid to economic recovery, the national forests, farm woodlands, national forest ranges, the acquisition of forest lands by public agencies, sustained-yield management and permanent communities, wildlife, recreational use of the forest, forest research, etc.

Ohio Forest News [February 1937] (*Ohio Forest News* [Ohio Sta.], No. 30 (1937), pp. 8, figs. 2).—This contains brief notes of a popular nature on the status of the forests, conservation activities, etc.

[Forestry investigations by the Pennsylvania Station], J. A. FERGUSON (*Pennsylvania Sta. Bul. 336* (1936), pp. 6, 31, 32).—Brief results are presented on planting distances for red pine, competition in experimental forest plantings, and spacing forest trees in plantings.

Physical and chemical studies of two contrasting clay forest soils, R. L. DONAHUE (*Jour. Forestry*, 35 (1937), No. 1, pp. 16-23, figs. 5).—In studies by the Mississippi Experiment Station of the total amounts of several important mineral elements in two contrasting forest soils, namely, fertile Sharkey clay from the Delta region and relatively infertile Lufkin clay from the Flatwoods region, the former was found higher in all the potential elements of fertility to the depths that soil samples are taken usually. However, at a depth of from 6 to 8 ft. the Sharkey clay contained less moisture, less organic and vola-

tile matter, less magnesium and silt-plus-clay, and no greater amounts of potassium, phosphorus, and nitrogen. Mechanical analyses showed little difference between the two soils, with indications that both contained too much silt-plus-clay and too little sand for the best growth of trees.

Some soil characters influencing the distribution of forest types and rate of growth of trees in Arkansas, L. M. TURNER (*Jour. Forestry*, 35 (1937), No. 1, pp. 5-11).—Based on studies conducted by the Arkansas Experiment Station, the author concludes that soil features influencing the supply of available water appear to be more influential than other factors in determining the rate of growth of pine trees. Among factors influencing water movement are degree of slope and the depth and physical structure of the different horizons.

The effect of frequent fires on profile development of longleaf pine forest soils, F. HEYWARD (*Jour. Forestry*, 35 (1937), No. 1, pp. 23-27, figs. 2).—The greater percentage of longleaf pine forest soils is said to be morphologically more similar to grassland than forest, the A₁ horizon being dense and relatively impenetrable. Where fire was excluded there developed a forest floor 2 to 3.5 in. thick, which permitted the establishment of an active soil fauna and a penetrable and porous A₁ horizon. Periods of fire exclusion as short as 10 yr. brought about great changes in soil characteristics.

Growth of Douglas fir trees of known seed source, T. T. MUNGER and W. G. MORRIS (*U. S. Dept. Agr., Tech. Bul. 537* (1936), pp. 40, figs. 7).—Seedlings grown from seed collected in the fall of 1912 in 13 different localities in western Washington and western Oregon, all within the commercial range of the species, were planted in replicated plats on burned-over uncultivated soil in four localities and at five different elevations ranging from 1,100 to 4,600 ft. The trees were observed and measured in 10 different years from 1915 to 1931.

An analysis of the data indicated that the age of the parent trees, the quality of their growing site, their growing space, and their condition as to fungus infection had exerted no influence on the height growth of the progeny. On the other hand, the altitude at which the parent trees grew did in some instances affect greatly the performance of the progeny. One stock from a high altitude made much less than the average growth when planted in the equable climate of the Oregon coastal hills and grew much better than average at high elevation in the Cascades. In contrast, a stock from the Oregon coastal hills made less than average growth when planted at high altitudes but thrived at low elevations. Several stocks grew equally well in all localities, indicating a greater adaptability to environment. Two of the stocks made unusual height development at each trial station, and since no character of the parents could be associated with this height supremacy, the quality is attributed to inherent variations. Mortality in the plantations could not be associated with seed source. Marked differences were noted in the dates at which the various progenies burst their leaf buds, and since occasional severe frost injury followed early bursting of the buds, it is considered advisable to match seed source with planting site on a basis of climate unless the stock is of proven adaptability. The quality of the sites upon which the test plantations were established had a profound effect on growth irrespective of the source of the stock. A temporary stimulus to seedling growth was imparted by large seed.

Notes on the terminal growth of coniferous plantations in the Hudson Highlands, H. H. TAYLOR and R. F. FINN (*Black Rock Forest Papers*, 1 (1937), No. 9, pp. 53-56, figs. 3).—Measurements taken in plantings of *Picea glauca*, *P. abies*, *Pinus resinosa*, *Larix decidua*, and *L. gmelini* indicated that the first three species reach their maximum weekly terminal growth during the last week of May. The deciduous larches reached their maximum considerably

later. As a result the authors suggest that release cuttings of competing hardwoods should be made in early spring before these maxima are attained in order to secure the greatest benefits from thinning.

Diameter outside bark as an index of bark thickness at breast height for red and chestnut oak, H. F. SCHOLZ (*Black Rock Forest Papers, 1 (1937), No. 8, pp. 49-52, fig. 1*).—Based on measurements in 459 chestnut oak and 418 red oak trees, the author suggests that diameter inside the bark and bark thickness of the two species is in the Hudson Highlands region a function primarily of the diameter outside the bark and secondarily of various other factors such as site, stand density, and age.

Cordwood volume tables for red oak and red maple in the Hudson Highlands, H. H. TRYON and R. F. FINN (*Black Rock Forest Papers, 1 (1937), No. 7, pp. 45-47*).—The included tables, according to the authors, are accurate to the extent of a variation not greater than 4 percent from actual yields.

Harvesting and marketing timber in New York, R. J. HOYLE (*N. Y. State Col. Forestry, Syracuse Univ., Tech. Pub. 49 (1936), pp. 186, figs. 59*).—This is a discussion of the harvesting of trees and forests and the preparation of the crude products for use or further manufacture.

Structure, occurrence, and properties of compression wood, M. Y. PILLOW and R. F. LUXFORD (*U. S. Dept. Agr., Tech. Bul. 546 (1937), pp. 32, pls. 9, figs. 8*).—Compression wood, one of the abnormal types formed by coniferous species under certain environmental conditions, as a rule on the lower sides of non-vertical trunks and branches, is characterized by high and irregular longitudinal shrinkage, low strength for its weight, and excessive hardness. An increase in the amount of deviation of trunks from the vertical, or an increase in the rate of diameter increment of individual trees, or both, tend to increase the formation of compression wood.

Microscopical examinations showed the summerwood tracheids of compression wood to be nearly circular in cross section as compared with a rectangular aspect in normal wood. The fibrils of the secondary cell walls in the compression wood made a higher angle in relation to the longest axis of the cells. The lignin content was slightly higher and the cellulose content slightly lower in compression wood. Pronounced compression wood was from 15 to 40 percent heavier than normal wood and longitudinal shrinkage in drying was much greater. Transverse shrinkage was less than normal. The lower strength properties in compression wood are associated closely with the differences in the slope of the fibrils. When manufactured into lumber, compression wood is accountable for much bowing and twisting.

Among silvicultural measures suggested to reduce compression wood are the early removal of defective and crooked trees, proper spacing to insure uniform growth, and the avoidance of large and irregular openings in the crown canopy to permit the entrance of violent winds.

Forest fire insurance in the Pacific Coast States, H. B. SHEPARD (*U. S. Dept. Agr., Tech. Bul. 551 (1937), pp. 168, figs. 17*).—The several sections discuss the need for forest fire insurance, the principles of fire insurance applicable to forest properties, practical considerations in the application of forest fire insurance, the contributive, causative, and conflagration hazards, forms of insurance recommended, and rate schedule construction.

"The outcome of the inquiry is, in brief, a recommendation in favor of forest fire insurance in the Northwest as a feasible and profitable undertaking where proper precautions are observed. The normal loss expectation from ordinary fire occurrence averages 0.082 percent per year, but it is recommended

that commercial forest fire insurance introduced in these regions be based on an average premium rate of 0.450 percent."

DISEASES OF PLANTS

The Plant Disease Reporter, February 15 and March 1, 1937 (*U. S. Dept. Agr., Bur. Plant Indus., Plant Disease Rptr.*, 21 (1937), Nos. 3, pp. 41-68, pl. 1, figs. 2; 4, pp. 69-83, fig. 1).—The following items of interest are included:

No. 3.—Early appearance of tobacco downy mildew (*Peronospora tabacina*) in Georgia in 1937, by J. G. Gaines; dates of first appearance of tobacco downy mildew (a list of the earliest dates reported to the Plant Disease Survey in the various States for 1921 and 1931-36); report of the work of the Tobacco Disease Survey Committee for 1936, compiled by L. Shaw; occurrence of curly top on vegetables and other susceptible hosts in the Pacific Northwest in 1936, by B. F. Dana; *Ascochyta lycopersici* leaf spot of potato in Oregon, by F. D. Bailey and R. Sprague; heavy leaf rust (*Puccinia coronata*) infection of cereals in Georgia, by H. W. Rankin; *Cytospora kunzei* canker of spruce (*Picea* spp.), by A. M. Waterman; tree diseases in Massachusetts, by M. A. McKenzie; distribution of *Cephalosporium* and *Verticillium* on elm in Massachusetts (with map and tabulation), by E. M. Johnson; winter injury to tree and small fruits in Idaho (with tabulations of temperatures of weather stations), 1935-36, by E. C. Blodgett; effects of the autumn 1935 cold wave on forest trees in northern Idaho, and effect of early frosts on *Pinus monticola* in northern Idaho in 1935, both by R. K. Pierson and J. Ehrlich; and effects of the autumn 1935 cold wave on ornamentals in northern Idaho, by G. W. Woodbury.

No. 4.—Freedom from "yellows" of certain plantings of the Blakemore strawberry, by P. H. Millar; late fall damage to strawberries by leaf scorch (*Diplocarpon earliana*=*Mollisia earliana*), by G. M. Darrow and E. B. Morrow; corn ear rots in plats at the University of Illinois, 1936, by B. Koehler; a list of diseases found on economic plants on Staten Island (Richmond County), N. Y., from 1932 to 1936, by M. B. Linn; plant diseases observed in southern California in 1936, by H. G. MacMillan and O. A. Plunkett; and deciduous-seedling diseases in Midwest nurseries (including *Rhizoctonia* and *Pythium* isolates), by E. Wright.

[Plant disease work by the Florida Station] (*Florida Sta. Rpt. 1936*, pp. 60, 61, 62, 64, 65, 80, 81, 82, 83-93, 94-96, 107-110, 113, 114, 134-137, 140, 141, 143, 153, 154).—Reports of progress are included on "chlorosis" in corn and other field crop plants, by R. M. Barnette; bronzing or copper leaf of citrus, by C. E. Bell and R. W. Ruprecht; blackheart of celery, by E. R. Purvis and Ruprecht; development of strains of cowpeas and beans resistant to root knot, by J. R. Watson and H. E. Bratley; cold storage of citrus fruits (including control of stem-end rot and *Penicillium* mold), by A. L. Stahl and A. F. Camp; zinc as a corrective for frechening of citrus, by Camp; spectographic studies of the composition of tissues and corresponding soils of normal and physiologically diseased horticultural crops (including tabulations of the comparative zinc content of normal, diseased, and zinc-treated tung foliage, and of normal and freched citrus foliage), by L. W. Gaddum, Camp, and W. Reuther; downy mildew (*Peronosplasmopara cubensis*) of cucurbits, by G. F. Weber; optimum time for setting strawberries in Florida, by A. N. Brooks; disease control in potatoes (including *Rhizoctonia* and *Sclerotinia* rot), and investigation and control of brown rot of potatoes and related plants caused by *Bacterium solanacearum* [*Phytophthora solanacearum*], both by A. H. Eddins;

investigation and control of fungus diseases of watermelons, including the wilt disease caused by *Fusarium niveum*, by M. N. Walker; so-called "rust" of *Asparagus plumosus*, by W. B. Shippy; control of tomato wilt (*Fusarium lycopersici*) in Florida, by Weber and D. G. A. Kelbert; *Glytocybe tabescens* mushroom root rot of citrus and other woody plants in Florida, by A. S. Rhoads; strawberry wilt or crown rot, by Brooks; tests of chemicals to check decay of citrus fruits in storage, by W. B. Tisdale and E. West; a bark disease of Tahiti lime trees, by Tisdale; *Sclerotium rolfsii* in Florida—its host relations and factors influencing its pathogenicity, by West; rose diseases in Florida and their control, by Shippy; fruit rots of grapes, by K. W. Loucks; virus diseases of tomato and pepper, by Brooks; and miscellaneous studies, including a cantaloup variety resistant to down mildew, citrus gummosis, and strawberry strain tests.

Progress reports are included of work at the Citrus Substation on melanose of citrus and its control, by G. D. Ruehle and W. A. Kuntz; die-back of citrus, by B. R. Fudge; citrus scab and its control, by Ruehle; and stem-end rot of citrus caused by *Phomopsis citri*, by Kuntz. Similar reports by the Everglades Substation include the seed- and soil-borne diseases and leaf blights of vegetable crops (bean, celery, lima bean, tomato, and potato), by G. R. Townsend; and nematode investigations, by J. R. Neller and A. Daane. Reports of work at the North Florida Substation include field and laboratory studies of tobacco diseases, and the developing of strains of cigar-wrapper tobacco resistant to black shank, both by L. O. Gratz and R. R. Kincaid. At the Subtropical Substation, work was conducted on bacterial soft rot of potatoes due to *Erwinia carotovora* [= *Bacillus carotovorus*], control of potato disease in Dade County, and control of tomato diseases by spraying, all by Ruehle.

[Phytopathological studies by the Pennsylvania Station] (*Pennsylvania Sta. Bul.* 336 (1936), pp. 26, 27).—Brief reports are included on barberry eradication, by F. D. Kern and H. W. Thurston; mushroom diseases, by W. S. Beach; disease-resistant potatoes, by E. L. Nixon; and tobacco wildfire, by Beach and D. E. Haley.

[Plant disease work by the South Carolina Station] (*South Carolina Sta. Rpt.* 1936, pp. 32-39, 93, 94, 126-130).—The progress is herein noted relative to studies on cotton wilt, by G. M. Armstrong; cotton seedling diseases (including the germination of seed with reference to locality of origin, seed treatments, and varietal resistance to anthracnose), by C. H. Arndt; cucurbit diseases, by C. J. Nusbaum; spraying for tobacco downy mildew (blue mold) control at the Pee Dee Substation, by W. M. Lunn; and bean diseases and potato disease control tests (*Rhizoctonia* and late blight) at the Truck Substation, by W. D. Moore.

[Plant disease studies by the Utah Station] (*Utah Sta. Bul.* 276 (1936), pp. 27-32, figs. 3).—Progress reports are included on chlorosis control, with special reference to grapes, by F. B. Wann and A. L. Wilson; peach mosaic, differences in healthy curly top and bean-tomato tissues, and tomatoes grown in shade less susceptible to curly top, all by Wann; *Verticillium* wilt more responsible for tomato crop failures than *Fusarium* wilt, fermentation method of seed extraction for tomato bacterial canker control, and curly top highly destructive to beans and tomatoes, all by H. L. Blood; bacterial soft rot of dahlia due to *Bacillus carotovorus* [= *Erwinia carotovora*], the increase of bacterial wilt of alfalfa since its discovery in 1925, strawberry root rot as a definite limiting factor, and the nematode factor in diseased strawberry roots, all by B. L. Richards.

[Plant disease studies at the Wyoming Station] (*Wyoming Sta. Rpt. 1936*, pp. 4-6, 26, 27).—Progress reports are given on the following: Chlorosis of cottonwoods; varietal reactions to black stem rust of oats, wheat, and barley and to bunt of wheat; control of wheat bunt and scab; alfalfa strains resistant to bacterial wilt; seed treatment of beans, peas, and sweet corn with Semesan; and spraying for the control of purple top of potatoes.

A race of crown rust to which the Victoria oat variety is susceptible, H. C. MURPHY and M. N. LEVINE (*Phytopathology*, 26 (1936), No. 11, pp. 1087-1089).—In this cooperative study between the Iowa and Minnesota Experiment Stations and the U. S. D. A. Bureau of Plant Industry, this variety, resistant to some 37 physiologic races of *Puccinia coronata avenae*, is reported as susceptible to a recent collection made in Texas, which is here designated as a new race (key number 41). The reactions of the standard differential varieties to this race are tabulated.

At present, for every known parasitic race of rusts or smuts of oats, an oat variety fully resistant to such race is known.

Diseases and pests of our textile plants, K. FLACHS (*Nachr. Schädlingsbekämpf.*, 11 (1936), No. 1, pp. 6-28, figs. 13; *Eng. abs.*, pp. [53, 54]).—This is a general summary on the fungus and phanerogamic parasites, nonparasitic diseases, and insect pests of flax and hemp, including control methods. A bibliography is included.

[Phytopathological work at the Wyoming State experiment farms] (*Wyoming Sta. Bul. 219* (1937), pp. 36, 37).—Progress reports are given on work with stem wilt of potatoes, potato storage as influenced by bin treatments, and spraying for purple top of potatoes.

Studies on the interfertility of four strains of *Puccinia helianthi* Schw., A. M. BROWN (*Canad. Jour. Res.*, 14 (1936), No. 10, Sect. C, pp. 361-367, pl. 1).—"A distinct strain of *P. helianthi* was collected on each of the following four species: *Helianthus annuus*, *H. petiolaris*, *H. tuberosus*, and *H. subtuberosus*. All possible combinations of reciprocal crosses, haploid pustule with haploid pustule, and haploid pustule with diploid pustule were made among these four strains. Interfertile strains, when crossed, give rise to aecia in the formerly haploid pustules. On this basis, the strains fell into two groups: (1) The strains on *H. annuus* and *H. petiolaris*, and (2) the strains on *H. tuberosus* and *H. subtuberosus*. The two strains in each group were highly interfertile, but the two strains of one group were highly intersterile with the two strains of the other group. A parallelism exists between the crossing behavior of certain varieties of *P. graminis* and that of these two groups. It is suggested that each of these two groups of *P. helianthi* may represent a variety."

The longevity of smut spores in herbarium specimens, G. W. FISCHER (*Phytopathology*, 26 (1936), No. 12, pp. 1118-1127).—In this study by the Washington Experiment Station, 77 species of smut fungi, represented by 387 specimens, were tested for spore longevity. In all, 24 species (80 specimens) contained viable spores. In general, the Tilletiaceae retained viability longer than did the Ustilaginaceae. Some species in both families possessed great spore longevity under these conditions, the most noteworthy records being *Tilletia levis* 25 yr., *T. tritici* 18 yr., *Ustilago hordei* 23 yr., *U. avenae* 13 yr., *Sphacelotheca sorghi* 13 yr., and *U. bromivora* 10 yr. Considerable differences were noted in various collections of the same age and species. These are thought to be correlated chiefly with the degree of maturity at collection.

The isolation of a toxic substance from the culture filtrate of *Trichoderma*, R. WEINDLING and O. H. EMMERSON (*Phytopathology*, 26 (1936), No. 11, pp. 1068-1070).—From liquid culture media on which an isolate of the fungus

T. lignorum had been grown, extraction with chloroform removed a gum and a crystalline substance, both highly toxic to *Rhizoctonia solani* and other fungi. By recrystallizing the latter substance from alcohol or benzene, it was obtained as white needles, analysis of which suggested the formula $C_{14}H_{13}N_2S_2O_4$, with the following determined constants—molecular weight 347, optical rotation $[\alpha]_D^{19} = -239^\circ$ in chloroform, and decomposition points after 3 recrystallizations from alcohol or benzene 219° and 222° C., respectively. The substance was much less soluble in water than in fat solvents. Sulfur was split out rapidly by boiling with aqueous KOH.

Virus studies, I, II (*Canad. Jour. Res.*, 14 (1936), No. 11, Sect. C, pp. 412-418, pl. 1).—Two papers are included.

I. *The production of antisera in chickens by inoculation with potato X*, W. Newton and H. I. Edwards (pp. 412-414).—"Chicken antiserum was produced by three wing-vein inoculations with sap from *Datura meteloides* and *D. stramonium* plants infected with 'potato virus X.' Before injection, the saps were purified by the Bawden and Pirie method. This antiserum formed a conspicuous precipitate when incubated for 3 hr. at 37° C. with similarly purified sap of these two plant species when they were infected with the X or healthy potato virus, but failed to form any precipitate when incubated in the same way with purified sap from virus-free plants. Two unknown viruses, one from spinach and the other from tomato, were established as belonging to the X group by the precipitin reaction through the use of chicken antisera. The serological grouping was supported by the fact that the unknowns had similar, if not identical, lethal temperatures, longevity in vitro, and host ranges as the ordinary potato virus X."

II. *Streak X, a disease of tomatoes caused by a virus of the potato X group unassociated with tobacco mosaic*, W. Newton (pp. 415-418).—"A streak disease of tomatoes was found to be caused by a virus of the potato X group unassociated with tobacco virus 1. The disease markedly reduced the yield of marketable fruit in several greenhouses near Victoria. The symptoms resemble those induced by ordinary potato virus X in conjunction with tobacco mosaic. The host range, lethal temperature, longevity in vitro, and dilution extinction point of the virus resemble ordinary potato X. Streak X may be distinguished from ordinary potato X by the more pronounced symptoms it induces on tobacco, *Datura*, *Nicotiana glutinosa*, and tomato, and particularly by the streaking and necrosis of the stems and leaves of tomato. The virus causing this streak disease could not be recovered from Irish Cobbler potatoes after an incubation period of 10 days, neither did the characteristic symptoms occur on tomatoes already infected with the ordinary potato virus X. The virus was recovered unchanged from X-free potato seedlings. The antigen reaction also proved that the streak virus belonged to the potato virus X group."

The histology of the necrotic lesions induced by virus diseases, F. M. L. SHEFFIELD (*Ann. Appl. Biol.*, 23 (1936), No. 4, pp. 752-758, pls. 2).—It is shown that, in *Nicotiana glutinosa* inoculated with aucuba mosaic, after 12 hr. a yellow substance, readily taking dyes, forms in the walls of a few cells between the lower epidermis and spongy parenchyma, spreading outward and upward while mitoses without cell division occur in the spongy cells. After about 3 days this substance occurs in the walls of all cells in the necrotic area. The author feels that this material isolates the cells, causing their death and preventing the virus from passing into healthy parts.

The part played by auxin in the formation of internal intumescences in the tunnels of leaf miners, C. D. LA RUE (*Bul. Torrey Bot. Club*, 64 (1937), No. 2, pp. 97-102, fig. 1).—The internal outgrowths discussed strongly

resemble certain intumescences often developed on the surfaces of leaves and stems, and they were experimentally induced on the exposed mesophyll of leaves of *Mitchella repens* and *Aster laevis* by fecal pellets from a number of insect larvae and from mice.

Oil sprays: Chemical properties of petroleum oil unsaturates causing injury to foliage, R. P. TUCKER (*Indus. and Engin. Chem.*, 28 (1936), No. 4, pp. 453-461).—The data presented are believed to indicate that the hydrocarbons of petroleum oils are not toxic to foliage in a chemical sense until oxidized to oil-soluble asphaltogenic acids. The unsaturated hydrocarbons, per se, are thus no more toxic to foliage than are the saturates. The amount of asphaltogenic acids which an oil must contain to be injurious proved to be relatively small. It was indicated that the formation of asphaltogenic acids is roughly proportional to the percentage of unsaturated hydrocarbons in an oil.

Associations of microorganisms in relation to seedling injury arising from infected seed, J. J. CHRISTENSEN (*Phytopathology*, 26 (1936), No. 12, pp. 1091-1105, fig. 1).—The results of this study by the Minnesota Experiment Station indicate that the soil microflora has no marked effect on seedling blight arising from *Helminthosporium* or *Fusarium* infected barley seed. Addition of *Trichoderma lignorum* and several other fungi and bacteria to spontaneously infected barley seed or to sterilized and nonsterilized soil and soaking infected seed in an extract of these organisms failed to inhibit or delay the parasitic action of seed-borne parasites. However, addition of such organisms to seed or sterilized soil inoculated with *H. sativum* increased the stand, decreased the number of deformed and stunted plants, and suppressed the seedling injury.

Spontaneously infected barley seed is one of the primary sources of seedling injury in the State. Treating such seed with Ceresan improved the stand, decreased the seedling injury, and materially increased the plant vigor. Preliminary tests with New Improved Ceresan also gave good results.

A dangerous virus disease of turnip, rape, and rutabaga [trans. title], O. KAUFMANN (*Arb. Biol. Reichsanst. Land u. Forstb.*, 21 (1935), No. 4, pp. 605-623, figs. 10).—This study considers the frequency and significance of virus diseases in the Cruciferae, the symptoms and course of the disease in question in the three hosts investigated, artificial transmission by the sap, the natural vectors (leaf aphids and *Lygus pratensis*), and the economic significance and geographical distribution of the disease.

Seed disinfection, II, III (*Jour. Agr. Sci. [England]*, 27 (1937), No. 1, pp. 43-52, 53-66, pl. 1).—Continuing this series,* the two following papers are included.

II. Large-scale field trials on the disinfection of seed corn with mercury dust disinfectants, W. A. R. Dillon Weston, F. Hanley, and J. R. Boer.—It was found that bulk treatment of wheat, barley, and winter and spring oats with mercury dust compounds had no harmful effects when drilling followed the applications immediately nor in oats drilled 7½ weeks after. Wheat bunt and leaf stripe and net blotch of barley were effectively controlled.

III. Experiments on the germination of peas—seed protection by the use of disinfectant dusts containing mercury, C. C. Brett, W. A. R. Dillon Weston, and J. R. Boer.—The evidence adduced indicated that for sowings before March a suitable mercury dust compound gave an increased stand and yield, but the advantage for later sowings appeared doubtful. Apparently the chief value of the treatment lay in its protective action.

* *Jour. Agr. Sci. [England]*, 25 (1935), No. 4, pp. 628-649, pl. 1, figs. 4.

Alfalfa stem nematodes (*Oklahoma Sta. [Blen.] Rpt. 1935-36, pp. 170-174, fig. 1*).—This is a brief, general account of the disease due to *Tylenchus dipsaci*, including studies by F. M. Rolfs and G. [E.] Tennyson.

The epidemiology and control of asparagus rust [trans. title], H. BREMER (*Gartenbauwissenschaft, 10 (1936), No. 1, pp. 51-73, figs. 5*).—As shown by 4-yr. tests with overwintering teliospores of *Puccinia asparagi*, the majority were dead at the time of primary infection, the average portion still viable being about one-fourth. Buried teliospores overwintered in higher percentages than those on the surface. Laboratory tests indicated that, within the limits of from 7° to 30° C. and from 27 to 100 percent relative humidity, the viability was higher the cooler and drier the environment. Neither by 3 weeks at from -3° to -20° nor by daily fluctuations from -6° to +11° over a 2- to 3-week period were the teliospores appreciably injured. From the author's results and a critical survey of the literature, it is concluded that no relations exist between the overwintering of teliospores and winter weather or between the severity of an epidemic and the reigning weather conditions at the time of primary infection, but that a warm, dry summer promotes the spread of the disease. One of the most important predisposing factors in the epidemiology of this rust is said to lie in the fact that primary infection foci always occur in young plantings and escaped plants, these being the plants most susceptible to infection at the time of teliospore germination. Thus every expansion of asparagus culture leads, in its earlier years, to an increase in rust, since under such conditions larger numbers of susceptible plants are present.

Variety tests over 2 yr. indicated that the American rust-resistant "Washington" varieties become infected later and less severely than ordinary varieties.

Diseases, and insect and other pests, of the field bean in New York, W. H. BURKHOLDER and C. R. CROSBY (*N. Y. State Col. Agr., Cornell Ext. Bul. 58, rev. (1935), pp. 33, figs. 22*).—This is a fully illustrated compendium of bean diseases and pests and their control in New York State.

Invasion of cotton seed by Bacterium malvacearum, G. TENNYSON (*Phytopathology, 26 (1936), No. 11, pp. 1083-1085, fig. 1*).—In this study by the Oklahoma Experiment Station, B. [= *Phytophthora*] *malvacearum* was found to enter the cottonseed at the chalaza through the intercellular spaces of the basal cap, and each of four tests gave evidence of the porosity of this cap. Inoculated seed showed bacteria in the tissue underneath the cap and in the intercellular spaces of its tissue. Bacteria-laden raindrops and rill water proved to be the principal sources of infection.

A method for the control of cotton root rot in the irrigated Southwest, C. J. KING (*U. S. Dept. Agr. Circ. 425 (1937), pp. 10, figs. 6*).—The method successfully used in Arizona "consists in burying liberal quantities of organic manures in deep furrows in infested areas during the winter, irrigating to encourage rotting, and planting cotton over the decaying material in the spring. The control is more efficacious with successive treatments and should be continued over a period of years in order to build up and maintain an abundant microfloral population in the soil. The root rot fungus [*Phymatotrichum omnivorum*] does not thrive in the presence of great activity on the part of saprophytic organisms, and the cotton plants frequently escape infection. The method should be applicable to row crops in any part of the irrigated region where root rot exists."

New biological and experimental data on the mole disease of mushroom beds [trans. title], J. CHAZE and A. SARAZIN (*Ann. Sci. Nat., Bot., 10. ser., 18 (1936), No. 1, pp. 1-85, pls. 3, figs. 9*).—This fungus disease, causing great losses

to the mushroom industry, is associated with *Mycogone perniciosa* and a small-spored *Verticillium*. In the present memoir the authors deal with the technic used in studying the malady, the morphology and cytology of the associated parasites and of the host mushroom (*Psalliota*) attacked, the culture of the parasitic fungi in various media, inoculation tests, the factors influencing infection, and the natural immunity of the host through the secretion of antibodies. The formation of antibodies by *Psalliota* is believed to be the first example of "humoral secretion" known in the fungi.

A review of the disease problems confronting the Nebraska growers of certified seed potatoes, R. W. Goss (*Nebr. Potato Impr. Assoc. Ann. Rpt., 17 (1936), pp. 6-14*).—Statistics collected by the University of Nebraska on the percentage prevalence in Nebraska of various potato diseases, as disclosed by two field inspections and one bin inspection made for certification purposes each year from 1931 through 1935, are presented in tabular form and discussed in the text. Rugose mosaic, unmottled curly dwarf, curly dwarf, and leaf roll were never prevalent or serious, probably due to lack of abundance of the insect vectors and the ease with which, when present, these diseases are detected and promptly removed by the seed-potato grower. Mild mosaic was more common but not serious. Spindle tuber is the most important virus disease in the State. *Fusarium* wilt and *Fusarium* root and stem rot are common and losses serious. Blackleg is not serious, and early blight is rarely of great importance except in individual fields, mostly in early plantings, irrigated. *Rhizoctonia* is common, and scab is present everywhere in varying severity. "Hay-wire", a trouble unusually prevalent in 1935, in which plants are severely dwarfed and rosetted, is discussed and the symptoms described. No methods of transmission except the inarch graft had proved successful, but there is a possibility that the trouble is a virus disease transmitted by some specific insect not very abundant in the State. Psyllid yellows was reported in 128 out of 506 fields inspected, constituting a serious problem.

Copper deficiency in sugar beets, D. A. VAN SCHREVEN (*Phytopathology, 26 (1936), No. 12, pp. 1106-1117, figs. 2*).—Sugar beets of the Hilleshög variety were grown in water culture with and without addition of soluble copper (all chemicals previously twice recrystallized in double-distilled water). For comparison the white oat variety Zege was grown under the same conditions. In oats the very typical symptoms of reclamation disease appeared after 4 weeks. The beets without copper reacted very distinctly, after 19 days, with a light chlorosis beginning usually at the tips of the leaves and gradually spreading over the surface, which then presented a marbled appearance with the green veins showing prominently against a pale or yellowish-green background. Usually the outer leaves were most affected, the younger heartleaves remaining largely normal in appearance. After 2 mo. the chlorotic parts of the old leaves died, becoming gray, gray brown, or white.

Beets grown in the same solution plus copper were three times as large as in the copper-free solution. The ratio of weight of leaves to roots in diseased plants was 2.32, whereas in the healthy plants it was 0.83. The sugar content of affected beets was 15.2 percent and that of healthy beets 16.85 percent.

Evidently copper is essential to normal photosynthesis, as clearly shown by subjecting the leaves to the iodine-potassium test for starch. In this test the leaves of affected plants showed starch only along the leaf veins, while the healthy leaves showed its presence throughout.

A literature list of 47 titles is included.

Tobacco diseases (*Georgia Coastal Plain Sta. Bul. 26 (1936), pp. 97-101, fig. 1*).—General notes on tobacco diseases are followed by progress reports on

work relative to overwintering of tobacco mildew ("blue mold"), its control in hotbeds, and spray tests in beds and in the field; root knot control in plant beds; cultivation practices in relation to root knot control; and the effect of crop rotation on root knot (including 3-yr. rotations with individual crops, influence of length of rotation on root knot, and weed and forage crop rotations).

The relationship between the activity of tobacco mosaic virus suspensions and hydrion concentration over the pH range 5 to 10, R. J. BEST (*Austral. Jour. Expt. Biol. and Med. Sci.*, 14 (1936), No. 4, pp. 323-328, fig. 1).—Inactivation of the virus set in at about pH 7.8, and the fraction inactivated was progressively larger with increasing pH values until at pH 10.2 only about 0.5 percent of the virus added remained active. Between pH 8.0 and 8.9, corresponding, respectively, to 21 percent and 90 percent inactivation, the ratio

$\frac{[H^+]}{[\text{active virus}]}$ proved to be a constant, but this relationship failed to hold at pH values below 8. It is concluded that inactivation of the virus is associated with the neutralization of acidic groups.

The bearing of the results on the nature of the virus is discussed, and it is suggested that the groups thus neutralized form an integral part of the chemically reactive prosthetic groups of the virus.

Five years of tomato spraying, J. D. WILSON and H. A. RUNNELS (*Ohio Sta. Bmo. Bul.* 184 (1937), pp. 13-18).—With diseases absent or of minor importance, bordeaux mixture decreased the yield in 4 of the 5 yr. of trial, while in 1935, with early blight prevalent, the control afforded by the fungicides used increased the yield of treated plats over that of the controls. The addition of oil emulsion (a transpiration depressant) to bordeaux mixture (a transpiration accelerant) served to lessen the adverse effect on yield caused by the latter during the 2 yr. in which oil was used. An increase in the strength of the bordeaux mixture usually resulted in increased injury, and formulas high in hydrated lime and low in CuSO_4 proved more injurious than those with the proportions reversed. A number of copper-containing preparations of low solubility caused a smaller reduction in yield than bordeaux mixture. Copper oxychloride is apparently the most promising substitute for bordeaux mixture on tomatoes. The effects of various sprays on vegetative development of the plant were closely correlated with their effects on yield. Bordeaux mixture increased the amount of blossom-end rot over that on untreated plants during each of the 3 yr. when this disease assumed economic importance, whereas the oil emulsion decreased it.

Some chemical constituents of apple associated with susceptibility to fire-blight, A. A. NIGHTINGALE (*New Jersey Stat. Bul.* 613 (1936), pp. 22, figs. 4).—The preliminary experiments reported relative to the development of *Erwinia amylovora* [= *Bacillus amylovorus*] on extracted juice of apple trees of different growth status are believed to justify the conclusion that the relative concentration of carbohydrate and nitrogenous compounds in the host tissues and their balance with one another is of much greater importance in determining the development of the pathogen in the tissue than is the relative water content or the amount of resistance offered by the physical properties of the host cells. A relatively low carbohydrate, high organic nitrogen content was correlated with susceptibility, and the reverse with resistance.

The growth of *E. amylovora* in test tubes on agar made of the extracted juices from hard and soft trees of several apple varieties supported the results of greenhouse inoculations on trees receiving complete or nitrogen-lacking nutrient solutions. The organism grew well on agar made from succulent twigs,

low in carbohydrates and high in organic nitrogen, but poorly or not at all on that made from hard twigs, high in carbohydrates and low in organic nitrogen. Adding asparagine to the medium made from hard twigs favored the development of the bacteria, whereas adding sugar to agar made from the juice of soft twigs was unfavorable to their growth.

Soil conditions in relation to little leaf or rosette of fruit trees in California. A. KOZŁOWSKI (*Phytopathology*, 26 (1936), No. 11, pp. 1041-1049, fig. 1).—In this paper the author presents chemical and physiological analyses of water extracts from soils of affected orchards, and data on the physical condition, microbiological processes, and moisture relations of such soils in support of his previously published conclusion⁴ regarding the origin of this disease. His experiments, taken as a whole, convinced him that the trees under investigation had become so weakened by unfavorable soil conditions that they could no longer resist attack by certain weak parasites found invading their roots and aerial parts. "After a very careful study of little leaf for nearly 2½ yr. the writer came to the conclusion that that disease is due not to a supposed single factor, which has not thus far been found, but to the concerted action of various factors, such as climate, soil conditions, and micro-organisms."

Apple powdery mildew. C. E. BERWICH (*Phytopathology*, 26 (1936), No. 11, pp. 1071-1073).—In this study by the University of California, an optimum for germination of *Podosphaera leucotricha* conidia was indicated at from 19° to 22° C. and from 90 to 100 percent relative humidity. Infection took place at from 13° to 25°, with humidities near 100 percent.

Resistance to infection was found to increase with age of leaf but could be partially broken down by slight abrasion of the leaf surface. The appearance of the mycelium in the buds during winter suggests the probable survival in this form. Perithecia apparently play no part in the perennation of the fungus.

Sclerotium rolfsii as a disease of nursery apple trees. J. S. COOLEY (*Phytopathology*, 26 (1936), No. 11, pp. 1081-1083, fig. 1).—*S. rolfsii* is reported as attacking apple nursery trees and girdling them at the collar. The fungus was readily observed and isolated in the early stages of the disease, but isolation studies indicated that it often dies soon after killing the host.

Anguillulina pratensis in relation to root injury of apple and other fruit trees. P. A. ARK and H. E. THOMAS (*Phytopathology*, 26 (1936), No. 12, pp. 1128-1134, figs. 4).—Nematodes determined as *A. pratensis* were found in large numbers in roots of plum, peach, pear, and grapes, associated with little leaf disease. Injury was accompanied by necrotic spots on the fine rootlets, ranging from microscopic size to streaks several millimeters long. Infested roots were stunted and sometimes thickened and distorted. Numerous bacteria were associated with the nematodes inside invaded tissues. It is concluded that besides the direct injury that must follow nematode invasion of the feeding roots there may be an absorption of preformed toxic material produced by the organisms external to the roots.

Water-table effects.—II, Relative incidence of diseases on stone-fruit trees, A. FIKRY (*Egypt Min. Agr., Tech. and Sci. Serv. Bul.* 154 (1936), pp. [2]+52, pls. 43, figs. 23).—Continuing these studies (E. S. R., 72, p. 645), the growing of plum, peach, and apricot trees on plats with different soil and water-table levels, in which the soil was permeable and the water movement normal and free, indicated that a high subsoil water table renders the trees subject to gumming and death (a functional disorder) and to attacks of shot hole (*Clasterosporium carpophilum*), rust (*Puccinia pruni-spinosae*), and pow-

⁴ *Phytopathology*, 25 (1935), No. 2, pp. 275-278

dery mildew (*Sphaerotheca [pannosa]*) (on peach only). Varietal differences to the gumming disease among plums are noted, and peaches and apricots are said to be less affected than plums. Peaches were the most severely attacked by the shot hole fungus, and varieties of stone fruits differed in their susceptibility to the rust.

Infection studies with *Sclerotinia fruticicola* on brushed and nonbrushed peaches. M. A. SMITH (*Phytopathology*, 26 (1936), No. 11, pp. 1056-1060, figs. 2).—Infection of the nonbrushed surface of Elberta peaches occurred mainly via the hair sockets, the minimum period for infection being 8 hr. The most common method of infection of brushed fruit was via the broken hair sockets, the minimum infection time here being 4½ hr. Stomatal and direct infections were uncommon in either case. The rapidity of infection on the brushed fruit was apparently correlated with the relative susceptibility of the brushed fruit surface to germinating conidia.

A virus disease of prune. H. E. THOMAS and E. M. HILDEBRAND (*Phytopathology*, 26 (1936), No. 12, pp. 1145-1148, fig. 1).—This new virus disease, found in New York, renders the trees virtually worthless commercially, although not inducing death. It is apparently distinct from any previously studied disease of plum or prune in North America. Affected leaves become reduced in size and distinctly narrowed, serration and pubescence are suppressed, and there is considerable rugosity and mottling. Ordinarily the shoot internodes become distinctly shortened. A variable number of apparently healthy and fruitful branches occur in diseased trees. Although diseased trees may bloom profusely, only occasional fruits develop on affected branches due to abortion of many of the pistils.

Transmission occurred by budding and grafting from prune to plum and prune but not to cherry or peach. Infection resulted even though none of the buds survived long enough to produce leaves, and the symptoms appeared about 1 yr. after inoculation. The virus apparently spread most rapidly upward, distinctly less rapidly downward, and very slowly laterally in the trees. Insect transmission tests with aphids (*Myzus mahaleb* and *Aphis setariae*) were unsuccessful.

Mesophyll collapse of citrus leaves. A. R. C. HAAS (*Calif. Citrogr.*, 22 (1937), No. 3, p. 114, figs. 4).—The leaf trouble discussed in this contribution by the California Citrus Experiment Station is often referred to as "blasting", and is characterized by yellow, translucent, and gray to brown, corklike areas, chiefly on the lower side of the leaves. The cause appears to be associated with an inadequate water supply, which may be aggravated by red spider or mite injury. Other contributory factors are enumerated. The symptoms have been induced by drying the soil to varying degrees prior to irrigating.

Endoxerosis of lemon fruits as affected by the application of different amounts of irrigation water. E. T. BARTHOLOMEW (*Phytopathology*, 26 (1936), No. 12, pp. 1149-1154).—Three groups of trees were grown in soil tanks with a moisture equivalent of 11 percent and a wilting point of from 3.5 to 4 percent. During the first period of the test the trees received like amounts of water, while during the second period they were not irrigated until the soil mass had reached a moisture content of from 6 to 8 percent in group I, from 5 to 6 percent in II, and from 4 to 5 percent in III. The results obtained substantiated previous evidence that withdrawal of water from the fruit during periods of excessive temperature and low relative humidity is an important factor in the production of endoxerosis.

A cytological study of *Erysiphe polygoni* on *Delphinium*. R. F. ALLEN (*Jour. Agr. Res. [U. S.]*, 53 (1936), No. 11, pp. 801-818, pls. 8).—In this study by the California Experiment Station and the U. S. D. A. Bureau of Plant

Industry, the cytology and genetics of one of the powdery mildews is examined in the light of recent advances in other ascomycetes and in the basidiomycetes.

The cells of the vegetative mycelium of *E. polygoni* are long, straight, and uninucleate, and the hyphae showed no mutual attraction, though there was some evidence of cytoplasmic streaming through the septa. In sexual reproduction the hyphae swell toward each other, forming broad areas of contact. A nucleus may pass directly between hyphae, or communication may be established at the joined apexes or between short side branches of two hyphae. The opening between two fusing cells broadens rapidly, but there has been no indication that nuclear fusion occurs. Cell fusion is followed by growth with incomplete closure of the septa, resulting in chains of communicating cells or mazes which make up the bulk of the perithecium. These evidently sporophytic cells contain from one to several nuclei, and in their later growth the septa are completed and further cell divisions reduce the number of nuclei per cell.

When the perithecium is from 7 to 8 cells in diameter, the initial fusion cell and usually a few of the closely associated cells die. As the perithecium expands the cells of the inner wall grow centripetally, filling the central space. From the lower central area from 5 to 6 cells grow up to form asci, each ascus at first containing 2 nuclei, which soon fuse.

A bibliography of 60 titles is included.

The efficiency of baths used for the hot-water treatment of narcissus bulbs, L. N. STANILAND and D. R. BARBER [*Gt. Brit.*] *Mtn. Agr. and Fisheries Bul.* 105 (1937), pp. 5+29, pls. 5, figs. 8).—In studies over several years relative to the difficulties met with in the hot-water treatment of daffodil bulbs, the author found "that unsatisfactory results with bulb baths may be due to a number of different causes, all or any of which may be operating in any given instance. The factor that appears to have led most frequently to the survival of eelworms in treated bulbs is the use of sacks instead of rigid containers in the baths, but other factors such as inaccurate thermometers or incorrect steam pressures are little less important." Detailed results and recommendations are presented.

Thyrostroma compactum on *Ulmus pumila*, J. C. CARTER (*Phytopathology*, 26 (1936), No. 8, pp. 801-804, fig. 1).—In May 1936, *T. compactum* was found fruiting on cankerous tissues of *U. pumila* in Illinois. Above the canker the tree was wilted. The development of the tubercles and characteristics of the conidiophores and conidia are detailed. Attempts to germinate the conidia on media and to isolate the fungus from diseased sapwood, bark, or tubercles failed, but its relationship to the canker was obvious.

A die-back of Douglas fir, A. M. WATERMAN and J. A. MILLER (*Phytopathology*, 26 (1936), No. 8, pp. 804, 805).—In a planting of *Pseudotsuga taxifolia* on Long Island, an infection by a fungus identified as *Sphaeropsis ellisi* occurred in connection with a die-back of the new growth. A few neighboring trees of *Pinus nigra*, *P. strobus*, and *Picea pungens* were similarly affected.

The relation of the age of needles of *Pinus strobus* to infection by *Cronartium ribicola*, W. H. SNELL (*Phytopathology*, 26 (1936), No. 11, pp. 1074-1080).—The results (1) of artificial inoculations of potted white pines, of older pines in their natural environment, and of young planted pines; (2) of the exposure of potted pines to spontaneous infection; and (3) of observations of cankers on young planted pines appear to indicate that the current season's needles are to a greater or less degree more susceptible to *C. ribicola* than the second season's needles.

It is suggested that in such studies the use of pines potted in the same season in which they are to be inoculated or exposed to infection may be open to criticism.

Progressive intensification of uncontrolled plant-disease outbreaks, S. B. FRACKER (*Jour. Econ. Ent.*, 29 (1936), No. 5, pp. 923-940, figs. 12).—The author's conclusions are "that the progressive intensification of white pine blister rust follows the same general type of development as that of human population and that there are several convenient ways in which it can be measured: (1) The rate of increase may be represented by m in the logistic curve used in studies of human population; (2) the extent of the gradual suppression of or increase in the *Ribes* population, the most important factor in the environment from the blister rust standpoint, can be determined by introducing appropriate coefficients to represent acceleration in the same population equation; and (3) the effect of the distribution of the *Ribes* in a given environment can be measured by finding out how many more cankers are present per tree in the stand, in view of the percentage of infected trees, than would be there if the *Ribes* were scattered uniformly among the trees."

Diseases of tung trees in Louisiana, A. G. PLAKIDAS (*Louisiana Sta. Bul.* 282 (1937), pp. 11, figs. 6).—The results of a preliminary survey of the diseases affecting tung trees in the State are presented. These include bacterial leaf spot (*Bacterium aleuritides*); nut rot, probably due to *Dothiorella ribis* (= *Botryosphaeria ribis*); branch and twig cankers associated with *Dothiorella* sp.; crown girdle (cause unknown); intervenal browning and translucent spotting of the leaves, both probably nonparasitic in nature; and "white tree", characterized by the whitish appearance of the leaves and the lighter color of the bark and fruit (cause unknown). Bronzing and root knot have not been seen in Louisiana.

The biology of *Pleurotus corticatus* Fries, F. H. KAUFERT (*Minnesota Sta. Tech. Bul.* 114 (1936), pp. 35, figs. 11).—In *P. corticatus*, isolated from fire-scarred and decayed hardwood trees in the Delta region of Louisiana and Mississippi, binucleate conidia were formed on coremia which developed from the dicaryotic vegetative mycelium and abortive and fertile sporophores. Simple, binucleate conidia were also formed singly on the dicaryotic mycelium. Uninucleate conidia were formed on coremia on the haploid mycelia developing from single basidiospores. Simple conidia formed singly were also developed on the haploid mycelium. Numerous large sporophores capable of producing basidiospores were developed in culture. The sporophores proved very resistant to decomposition by molds or bacteria. For vegetative growth the optimum was about 27° C., and the most favorable medium used was malt agar.

When haploid mycelia from the same sporophore were mated, four types of reaction resulted, viz, compatible, neutral, antagonistic, and inhibitory. These are described, and it is stated that so far as known the inhibitory type has not hitherto been observed in other agarics. These experiments indicate the fungus to be heterothallic and tetrapolar. The diploidization of haploid by dicaryotic mycelia is described.

The dicaryotic mycelia caused the greatest decay of basswood blocks at a moisture content of 110-130 percent and rotted basswood sawdust more rapidly than haploid mycelia in tests of 90-150 days' duration. However, after 210 days the haploid mycelia caused as much decay as the parent dicaryotic or compatible matings of haploid mycelia. The antagonistic and neutral matings of haploid mycelia rotted basswood sawdust to the same extent as haploid cultures,

viz, about one-third to one-half as fast as the dicaryotic mycelia or compatible pairs of haploid mycelia. The inhibitory pairs of haploid mycelia rotted sawdust much more slowly, viz, only one-third as fast as the haploid mycelia and from one-seventh to one-eighth as fast as the parent dicaryotic cultures.

Coremia and conidia are formed on and in basswood blocks, thus supporting the theory that the fungus may be disseminated spontaneously by termites or other insects.

The feeding of hollow-spear nematodes on other nematodes, M. B. LINFORD and J. M. OLIVEIRA (*Science*, 85 (1937), No. 2203, pp. 295-297).—In this study at the Pineapple Experiment Station of the University of Hawaii, the habit of preying upon nematodes was found well developed in the genera *Aphelenchoides*, *Dorylaimus*, *Discolaimus*, and *Actinolaimus*, all inserting the spear into their prey and sucking out through it the body contents. Larvae and eggs of the root knot nematode (*Heterodera marioni*) and larvae and adults of *Anguillulina pratensis* were attacked. About 13 species of dorylaims and 2 of *Aphelenchoides* were identified as predators. Prompt paralysis of the prey followed piercing by the spear. The sucking process and salivary flow are described.

ECONOMIC ZOOLOGY—ENTOMOLOGY

[Notes on economic insects and their control] (*Jour. Econ. Ent.*, 30 (1937), No. 1, pp. 210-216, fig. 1).—The notes presented (E. S. R., 76, p. 501) are as follows: Sugar Beet Leafhopper (*Eutettix tenellus* Baker) Appears in Illinois, by D. M. DeLong and K. J. Kadow (p. 210); Unusual Abundance of *Thyanta custator* (Fabr.) in South Dakota, by H. C. Severin (p. 210); Pyrethrins in Fresh Pyrethrum Flowers, by H. L. Haller (pp. 210, 211); Improved Device for Artificial Feeding of Aphids, by D. J. Pietsch (pp. 211, 212), contributed from the Minnesota Experiment Station; Dichloroethyl Ether for Wireworm [Sugar Beet Wireworm] Control, by R. E. Campbell and M. W. Stone (pp. 212, 213); Dichloroethyl Ether as a Control for Sod Webworms [*Crambus* sp.] in Lawns, by M. W. Stone and J. C. Elmore (p. 213); Preliminary Toxicity Tests With Horseflies, by D. MacCreary and A. M. Pearson (p. 214), contributed from the Delaware Experiment Station; High Infestation of *Prionus laticollis* Drury in Ohio, by C. R. Cutright (p. 215), contributed from the Ohio Experiment Station; Flight and Movement of Peach Borer Moths, by O. I. Snapp and J. R. Thomson, Jr. (p. 215); and A Scotch Pine Weevil, *Hyllobius radialis* Buchanan, by K. E. Maxwell and G. F. MacLeod (pp. 215, 216).

[Report of work in entomology and economic zoology by the Florida Station] (*Florida Sta. Rpt.* 1936, pp. 64, 65-69, 82, 114, 123, 124, 128, 129).—The work of the year referred to (E. S. R., 75, p. 653; 76, p. 65) includes the Florida thrips *Frankliniella cephalica bispinosa* Morg., by J. R. Watson; the introduction and propagation of *Leis dimidiata* var. *15-spilota* Hope, by Watson and W. L. Thompson; the southern green stinkbug, leaf-footed bug, and *Acanthocephala* sp., by H. E. Bratley; the bean jassid, by A. N. Tissot; the green citrus aphid, by Thompson and Tissot; insects affecting pecan trees, by G. B. Fairchild and Bratley; control of the arbor vitae aphid, by J. W. Wilson; the onion thrips, by Watson; the gladiolus thrips, by Watson and Wilson; the biology and control of the Florida aphids, by Tissot; the pepper weevil, by C. C. Goff and Wilson; fumigation research for the cigarette beetle, by R. J. Wilmot; control of the purple scale and white flies with lime-sulfur, by Thompson at the Citrus Substation; and miscellaneous insect pests, with particular

reference to methods of control, prevalence and control of the sugarcane borer in south Florida, and prevalence and control of rodents under field and village conditions, all by R. N. Lobdell at the Everglades Substation.

[Work in entomology by the Maine Station] (*Maine Sta. Bul.* 384 (1936), pp. 391-395, 401, 402, 427, 428, 430-434, figs. 3).—Included in the work referred to (E. S. R., 75, p. 374) are insects affecting the apple crop, particularly the apple maggot, apple seed chalcid, and apple leaf-curling midge *Dasyneura mali* Kieff., by F. H. Lathrop, and canning crops, including the Mexican bean beetle and pea aphid, by J. H. Hawkins; control of the striped cucumber beetle, also by Hawkins; insects in relation to the transmission of virus diseases, by G. W. Simpson; and blueberry insects, including the blueberry fruit-fly (*Rhagoletis mendax* Curran,* previously regarded as a blueberry race of *R. pomonella* Walsh), blueberry thrips *Frankliniella vaccini* Morg., blueberry flea beetle, and blueberry spanworm *Itame argillacearia* Pack., by Lathrop.

Montana insect pests for 1935 and 1936, A. L. STRAND (*Montana Sta. Bul.* 333 (1937), pp. 39, figs. 8).—In this report of the State entomologist (E. S. R., 72, p. 807), a discussion of grasshopper control both on cultivated lands and on the range in Montana, first presented, is followed by an account of other important insects of the biennium, including the pale western cutworm, Say's plant bug, beet webworm, various species of blister beetles with the spotted blister beetle predominant, the false chinch bug, fruit insects (the black cherry aphid, black cherry fruitfly, codling moth, oystershell scale, Vespidae, the pear slug, etc.), small fruit insects (the strawberry root weevil, strawberry leaf roller, and raspberry sawfly), the forest tent caterpillar, Virginia creeper leafhopper *Erythroneura comes siczac* Walsh, and the alpine rock crawler *Grylloblatta campodeiformis* Walk.

[Work in entomology by the Oklahoma Station] (*Oklahoma Sta. [Bien.] Rpt.* 1935-36, pp. 26-42, figs. 6).—Following reference to the occurrence of the important insects of the biennium (E. S. R., 73, p. 71), brief reports are made of surveys to determine the incidence of the hessian fly; the finding of calcium arsenate as the most effective insecticide for the cotton leaf worm, the resistance of the boll weevil to near-zero temperatures, weevil resistance of cotton, and damage to corn by the corn earworm influenced by tightness of the husk, all by E. Hixson; grasshopper poisoning baits, by F. E. Whitehead and R. R. Walton; extermination of red harvester ants by means of carbon disulfide, by F. A. Fenton and L. E. Coe; value of sulfur as a diluent in insecticidal dusts, by Whitehead; chinch bug control and chinch bug resistance of sorghums as shown by quantitative tests, both by R. G. Dahms and R. P. Snelling; causes for periodicity of chinch bug outbreaks, by Fenton and Dahms; possibility of chinch bug control indicated by hibernation observations, by Dahms and G. A. Bieberdorf; sulfur as an effective insecticide for control of the common red spider on elms, by Fenton and Coe; need for revision of apple spray schedules under Oklahoma conditions, by Bieberdorf; life cycle of the flat-headed borer for determining the control method, by Fenton and M. Maxwell; danger of use of summer oil sprays for elms for scale control, by Fenton and Walton; and new facts about the transmission of anaplasmosis, by C. E. Sanborn, G. W. Stiles, Jr., and L. H. Moe.

[Work in economic zoology and entomology by the Pennsylvania Station] (*Pennsylvania Sta. Bul.* 336 (1936), pp. 37-39).—The work of the year reported upon (E. S. R., 74, p. 366) relates to oil sprays and to the oriental fruit moth,

* Amer. Mus. Novitates, No. 526 (1932), p. 7.

both by S. W. Frost; mushroom insects and the tomato pinworm (noted on page 78), both by C. A. Thomas; spray residues, by H. Frear and H. N. Worthley; and the codling moth, by Worthley.

[Work in economic entomology and zoology by the South Carolina Station] (*South Carolina Sta. Rpt. 1936, pp. 39-50, 85-93, figs. 3*).—The work of the year reported upon (E. S. R., 75, p. 78) includes the results of a faunal survey, by F. Sherman; work with the Mexican bean beetle, particularly as related to the value of rotenone as a control measure, by Sherman and J. N. Todd; methods of wintering bees, by D. Dunavan; studies of the oriental fruit moth, the southern cornstalk borer, and the rice weevil in corn, all by O. L. Cartwright, and of cotton insects, including thrips (especially *Sericothrips variabilis* (Beach)) on seedling cotton and the cotton flea hopper, by J. G. Watts; bollweevil and miscellaneous cotton insect investigations, including field poison tests, cotton root aphids (the corn root aphid, *Trifidaphis phaseoli* (Pass.), and *Rhopalosiphum* sp.), a contribution relating to which has been noted (E. S. R., 76, p. 508), cotton leaf aphids (the cotton aphid and the cow-pea aphid), and several bollweevil parasites, by F. F. Bondy and C. F. Rainwater of the U. S. D. A. Bureau of Entomology and Plant Quarantine; and the relative toxicity of some insecticides to the tobacco flea beetle, by N. Allen, also of the U. S. D. A. Bureau of Entomology and Plant Quarantine.

[Work in entomology by the South Dakota Station], H. C. SEVERIN (*South Dakota Sta. Rpt. 1936, pp. 25-27*).—The work of the year reported upon (E. S. R., 75, p. 638) includes grasshoppers of the subfamily Cyrtacanthacrinae of South Dakota; pollinating agents of sweetclover in South Dakota, with special emphasis upon seed production as influenced by the honeybee; and a study of the blister beetles (Meloidae).

[Work in entomology by the Utah Station] (*Utah Sta. Bul. 276 (1936), pp. 20-26, figs. 4*).—The work of the biennium 1935-36 reported upon (E. S. R., 72, p. 359) included the finding that the value of range lands is materially lessened by consumption of large quantities of forage by insects, by G. F. Knowlton; data on the importance of control of the pale western cutworm and the invasion of Utah by bands of the Mormon cricket, both by C. J. Sorenson; extensive damage by the pea aphid to canning peas, by Sorenson and Knowlton; the boxelder bug, a serious household pest, by Knowlton; serious damage to grain and alfalfa fields by Say's stinkbug and the early determination of dates for cover spray applications for the codling moth, both by Sorenson; the possibility of control of the beet leafhopper, by Knowlton; effective grasshopper control by poisoned bait, by W. W. Henderson; reduction in alfalfa seed production by the tarnished plant bug, by Sorenson; insect damage to berry crops, biological control of *Paratrioxa cockerelli*, and the timing of control operations for tomato fruitworms, all by Knowlton; and further insect infestations, by Sorenson.

[Report of work in economic zoology and entomology by the Wyoming Station] (*Wyoming Sta. Rpt. 1936, pp. 10, 11, 17, 18*).—The work of the year in apiculture (E. S. R., 75, p. 85), dealing with wintering bees, use of 2 queens per colony, large v. small colonies for honey production, and a new culture medium for *Bacillus larvae*, and with tapeworms of sheep and rabbits (E. S. R., 75, p. 108) is referred to.

Observations on shade-tree insects and their control, E. P. FELT and S. W. BROMLEY (*Jour. Econ. Ent., 30 (1937), No. 1, pp. 71-75*).—A continuation of the annual report of observations (E. S. R., 75, p. 663), in which the occurrence and control of shade-tree insects in 1936 are dealt with.

Symposium: Insects affecting man (*Jour. Econ. Ent.*, 30 (1937), No. 1, pp. 9-71).—The following contributions are presented: Mosquitoes and Their Control, by T. J. Headlee (pp. 10-17), contributed from the New Jersey Experiment Stations; Mosquito Control and Wildlife Conservation—Two Distinct but Sometimes Overlapping Systems of Processes in Human Ecology, by R. D. Glasgow (pp. 17-20); Mosquitoes and Malaria, by L. L. Williams, Jr. (pp. 20-26); Need for an Organized Research Program in Mosquito and Malaria Control, by F. C. Bishopp (pp. 27, 28); Myiasis of Man, by W. E. Dove (pp. 29-39); Notes on Forms of Myiasis, by O. R. Causey (pp. 39, 40); Some Therapeutic Uses of Insects and Their Products, by W. Robinson (pp. 41-48); Scientific Approach in Insect-Therapy, by W. A. Riley (pp. 49-51); Ticks of the United States in Relation to Disease in Man, by R. R. Parker, C. B. Philip, G. E. Davis, and R. A. Cooley (pp. 51-69); and Need for Research on Parasitic Mites, by R. Matheson (pp. 69-71).

Review of United States patents relating to pest control [January-December 1936], R. C. ROARK (*U. S. Dept. Agr., Bur. Ent. and Plant Quar., Rev. U. S. Pat. Relat. Pest Control*, 9 (1936), Nos. 1, pp. 6; 2, pp. 7; 3, pp. 8; 4, pp. 8; 5, pp. 10; 6, pp. 10; 7, pp. 10; 8, pp. 8; 9, pp. 8; 10, pp. 11; 11, pp. 9; 12, pp. 8).—A continuation of this series (*U. S. R.*, 74, p. 665).

Methods and equipment for laboratory studies of insecticides, H. WATERS (*Jour. Econ. Ent.*, 30 (1937), No. 1, pp. 179-203, figs. 6).—Report is made of a study of methods and equipment for rearing test insects and food plants under standardized conditions that can be maintained throughout the year. An efficient method for growing certain types of plants in trays under controlled conditions, an automatic method for watering these plants, methods for rearing several species of test insects, and several new types of insect cages were developed.

Studies on calcium arsenate, H. WATERS and E. WITMAN (*Jour. Econ. Ent.*, 30 (1937), No. 1, pp. 204-210, fig. 1).—This contribution reports upon the determination of the factors involved in the formation of the so-called safe type of calcium arsenate and a method that was developed for making safe material on a commercial scale. A rapid laboratory test for arsenical injury to plants was developed and used extensively, and the comparative toxicity of the safe and ordinary types of calcium arsenate to several insect species was studied.

Homologs of paris green.—III, Members of the oleic and linoleic acid series, F. E. DEARBORN (*Jour. Econ. Ent.*, 30 (1937), No. 1, pp. 140-143).—In continuation of earlier studies (*U. S. R.*, 75, p. 514), the author reports that "crotonic, oleic, and erucic acids of the oleic series and linoleic acid of the linoleic series of fatty acids form definite complex compounds with copper and arsenic. The combining ratio of copper oxide to arsenious oxide is probably 4:3, the deviation from the theoretical value probably being due to the difficulty in purifying the compounds. From these conclusions the inference may be drawn that all the acids of the oleic and linoleic series of fatty acids form complex compounds of the general formula $3CuAs_2O_4 \cdot CuO$ (acid anhydride), similar to paris green."

Contact insecticidal properties of various derivatives of cyclohexylamine, C. W. KEARNS and W. P. FLINT (*Jour. Econ. Ent.*, 30 (1937), No. 1, pp. 158-166, figs. 4).—Tests of the insecticidal properties of 41 N- and N,N-substituted derivatives of cyclohexylamine, made on the aphid *Myzus persicae* Sand. and the common red spider, are reported upon. The relationship of toxicity to molecular structure is discussed in detail, and the relative toxicity of various closely related derivatives is represented by toxicity curves. N,N-amyl-benzoyl cyclohexylamine and N,N-amyl-acetyl cyclohexylamine were found to have exceptionally high contact insecticidal properties.

Relative toxic action of phenol and phenyl mercaptan, when the goldfish is used as the test animal, W. A. GERSDORFF (*Jour. Agr. Res.* [U. S.], 53 (1936), No. 11, pp. 841-847, fig. 1).—A study was made of the toxicity of phenol and phenyl mercaptan, the results being compared with each other and with those obtained with rotenone. Goldfishes weighing from 3 to 5 g each, and of the same lot, were used as test animals, observations being made at a constant temperature of 27° C.

"The phenolic solutions used were not so acid that the change in hydrogen-ion concentration was a factor to be considered. Phenol, like nicotine and anabasine, gives markedly skewed frequency distributions, in contradistinction to phenyl mercaptan and rotenone. The geometric mean defines best the position of the distribution in the case of phenol. It differs but little from the arithmetic mean in the case of phenyl mercaptan and rotenone.

"Phenyl mercaptan becomes toxic at much higher concentrations than rotenone (about 10 times as high), whereas phenol becomes significantly toxic (lethal within 3 days) at still higher concentrations than phenyl mercaptan (of the order of 40 times as high). Under the conditions of this study the threshold concentration of rotenone is about 0.04 mg per liter and that of phenyl mercaptan is about 0.4 mg per liter. That of phenol, however, cannot be approximated for comparison, since the initial acceleration of its velocity of fatality with increase in concentration is relatively slow.

"Phenol has a much more rapid toxic action than rotenone; its effect is immediately apparent, and there is practically no time tolerance at the higher concentrations. Phenyl mercaptan, although not wholly soluble at the higher concentrations required under the foregoing conditions, also has a rapid toxic action.

"All the compounds may be significantly compared quantitatively only at their regions of greatest toxic power, of which the minimum product of concentration and survival time is a measure. According to this criterion phenyl mercaptan is 7 times as toxic as phenol but only one-fiftieth as toxic as rotenone."

Variability in lead residues on apples, M. H. HALLER, C. C. CASSIL, and E. GOULD (*Jour. Econ. Ent.*, 30 (1937), No. 1, pp. 174-179).—In work conducted cooperatively by the U. S. D. A. Bureau of Plant Industry and Entomology and Plant Quarantine and the West Virginia Experiment Station, 11 spray treatments were applied to Stayman Winesap apples. "Each spray treatment was replicated 3 times on adjoining or closely adjacent trees. The fruit from each replication was kept separate, and duplicate 30-apple samples were taken from each replication for the determination of lead residue at harvest. Additional analyses of duplicate 15-apple samples were made with certain of the lots after various washing treatments. Considerable variation was found to exist between determinations within spray treatments. Statistical examination of the data showed that variations between duplicate determinations within replicates, representing sampling and analytical errors, were relatively small and due in part to the size of the apple in the samples. Variations between replicates within spray treatments would represent differences due to the application of the sprays or to differences in the growth condition of the trees. The variation between replicates both at harvest and after washing was found to be quite large and not attributable to the size of the fruit. These variations introduce a serious error that should be taken into account in the comparison of spray treatments."

Nicotine in oil: A promising insecticide for horticultural purposes, P. O. RITCHIE and R. K. CALFEE (*Jour. Econ. Ent.*, 30 (1937), No. 1, pp. 166-174, figs. 2).—In work at the Kentucky Experiment Station, free nicotine dis-

solved in highly refined petroleum distillate gave promise as a horticultural spray. When correctly applied, it did not burn even tender plants and gave a high percentage of kill of many insects with piercing-sucking and chewing mouth parts. "It is concluded that 1 percent free nicotine in oil is suitable for field and greenhouse use with a minimum of discomfort to the operator and has a toxicity equivalent to 0.1 percent pyrethrum in oil. It was found possible to dissolve free nicotine in oil by two methods. The first is by adding 100 percent free nicotine directly to the oil. The second is by shaking commercial free nicotine products, such as 50 percent, with the oil base and then separating off the oil-nicotine from the settled water and impurities." It is pointed out that nicotine in oil must be applied to plants in the form of a fine fog to avoid plant injury. Several new applicators have been devised and are described, one of which, a new hand continuous atomizer, appears to have immediate commercial possibilities.

Derris and cube: Approximate chemical evaluation of their toxicity, H. A. JONES and C. M. SMITH (*Soap*, 12 (1936), No. 6, pp. 113, 115, 117, figs. 2).—Reporting further (*E. S. R.*, 73, p. 345), a method of calculating from the percentage of rotenone and of total extractives the approximate toxicity of samples of derris or cube root to houseflies is considered. "It gives a figure that expresses the insecticidal value of the root in terms of the toxicity of rotenone, by adding to the rotenone content a value for the effectiveness of the remainder of the extract. For derris root, using total extractive values obtained with carbon tetrachloride or benzene, the expression is: Toxic value equals rotenone content plus 0.5 (total extractive content minus rotenone content). If the acetone extract content is used, the factor 0.5 should be replaced by 0.4. For cube root the expression is: Toxic value equals rotenone content plus 0.4 (total extractive content minus rotenone content), and this holds for extracts obtained with any of the three solvents mentioned."

The optical rotatory power of extracts of derris and cube roots, H. A. JONES (*Jour. Agr. Res. [U. S.]*, 53 (1936), No. 11, pp. 831-839, figs. 3).—Continuing his earlier studies (see above), the author found that values for rotenone equivalent to the combined optical rotatory powers of both acetone and benzene extracts of derris and cube roots gave an approximate measure of the insecticidal effectiveness of these materials to houseflies. Values calculated from the rotation of benzene extracts did not agree with toxicity so well as did the combined values, and in about half the samples results derived from the optical activity of acetone extracts were widely different from the toxicity values. The use of optical rotatory power is not recommended as a means of evaluation since simpler means of calculating the approximate toxic value are at hand. The results indicate that optically active constituents other than rotenone and deguelin were probably present in the samples tested. Dextro-rotatory materials were undoubtedly present in some of the samples of derris root.

Toxicity of rotenone powders, D. G. HOYER and M. D. LEONARD (*Soap*, 12 (1936), No. 3, p. 109).—Attention is called to the work of Jones, Campbell, and Sullivan (*E. S. R.*, 73, p. 345), which has shown that the total toxicity of rotenone-bearing root is greater than the amount of rotenone present would indicate, emphasizing the fact that other toxic extractives must be taken into consideration. It is pointed out that a more accurate method of comparing the toxic value of various rotenone-bearing roots is to determine the ratio between the percentage of rotenone and the percentage of total extractives present. The term "index of relative toxicity" is suggested for the figure thus obtained, it being considered a more accurate method of expressing the full toxic value of rotenone-bearing roots.

Rotenone powders, R. B. STODDARD (*Soap*, 12 (1936), No. 4, p. 107).—This is a critical discussion of the contribution by Hoyer and Leonard above noted.

Toxicity of rotenone powders, M. D. LEONARD and D. G. HOYER (*Soap*, 12 (1936), No. 6, pp. 117, 123).—A reply to the above.

[Contributions on termite control] (*Jour. Econ. Ent.*, 30 (1937), No. 1, pp. 87-98).—Contributions relating to termite control are: Problems in Termite Control, by D. M. Muirhead (pp. 87-91); Termite Control in Northeastern United States, by G. E. Sanders (pp. 92-94); and Relation of State Workers to Commercial Termite Control Companies, by N. Turner (pp. 94-98).

The field cricket as a pest of strawberries and its control, W. A. THOMAS and L. B. REED (*Jour. Econ. Ent.*, 30 (1937), No. 1, pp. 137-140).—The field cricket is a potential pest in the majority of the strawberry-producing areas in the Eastern States. In the North Carolina area it is responsible for a large percentage of the unmarketable berries that are found in the heavily infested fields. In addition, this pest often decreases the yield of fruit by feeding on the runner plants and on the developing fruit bud and blossoms. It can be controlled economically by the judicious use of poisoned baits during the early fruiting period or just prior to harvesting. The choice of poisons will depend on their availability, but calcium arsenate, sodium fluosilicate, and barium fluosilicate have given slightly better results than some of the other generally used insecticides. The choice of baits also will depend largely on their availability, but in the South, corn meal is available on practically every farm and is probably the most economical in this area.

Life history of the thrips parasite *Dasyscaphus parvipennis* Gahan and the technic for breeding it, S. M. DOHANIAN (*Jour. Econ. Ent.*, 30 (1937), No. 1, pp. 78-80).—The thrips parasite *D. parvipennis*, first reported in 1923 from Java, where it was reared from the onion thrips along with *Thripococcus brui* Vuil. and described by Gahan in 1927 as representing a new genus of the family Eulophidae, was reared from and reported, in 1927 and 1928, to be effective in controlling the red-banded thrips in the Gold Coast. It was introduced into Trinidad in 1935, where it became established, and from Trinidad into Puerto Rico in 1936. It is considered desirable that the parasite be introduced into the United States to combat the onion and the red-banded thrips, the latter occurring in Florida as an enemy of mango, jobo, and *Acalypha wilkesiana*. Notes on its life history, rearing, shipment, and liberation and recovery in Puerto Rico are included.

Cotton flea hopper control tests, using the Latin square plat arrangement and analysis of variance, J. C. GAINES (*Jour. Econ. Ent.*, 30 (1937), No. 1, pp. 119-125).—This contribution from the Texas Experiment Station deals with the Latin square method of plat arrangement for comparing materials used in control of the cotton flea hopper. The purpose of the investigation described was twofold, first, to determine if this plat or block arrangement, using small blocks, could be used in cotton-dusting control experiments, and, second, which material gives the best control of cotton flea hopper nymphs.

Recent insecticide experiments to control cotton flea hopper at Port Lavaca, Tex., K. P. EWING and R. L. MCGARR (*Jour. Econ. Ent.*, 30 (1937), No. 1, pp. 125-130).—In tests during the last 3 yr., derris root and cube root, in cage tests, gave practically no control of the cotton flea hopper, and other mixtures containing rotenone were also ineffective. "Pyrethrum dust containing 0.5 percent total pyrethrins was effective in killing adults (75 percent mortality) and was fairly effective against nymphs (57.7 percent mortality). The mixture of pyrethrum with sulfur increased the kill of nymphs but decreased the kill of adults. Phenothiazine was not effective in killing the cot-

ton flea hopper. Mixtures of paris green and sulfur, varying from 5 to 20 percent paris green, gave the most promising results in cage and field experiments. A mixture of 10 percent paris green and 90 percent sulfur gave better control of the cotton flea hopper than any other material used in field tests in 1935. Three cuts (where only two applications were made) produced an average gain of 220 lb. of seed cotton per acre over the checks. One experiment showed a gain of 596 lb. of seed cotton per acre from two applications of 10 percent paris green-sulfur and a net profit of \$23.11 per acre."

Large-scale sulfur-dusting experiments for cotton flea hopper control at Port Lavaca, Tex., K. P. EWING and R. L. MCGARR (*Jour. Econ. Ent.*, 30 (1937), No. 1, pp. 130-134).—In experiments conducted in connection with those above noted, "fields of cotton ranging in size from 17.5 to 76 acres were dusted with sulfur for cotton flea hopper control on 10 farms in Calhoun County, Tex., in 1935. Adjoining untreated areas were left on each farm for comparison. On account of heavy rains early in June, only 2 of the experiments were started early enough to secure maximum control. Two to 4 effective applications of sulfur were made. The average amount of sulfur used per acre was 62.1 lb. The cost per farm ranged from \$1.86 to \$3.45 per acre, the average being \$2.69 per acre. Average gain in production from the sulfur dusting in the large-scale experiments was 167.5 lb. of seed cotton per acre. This showed an average net profit of \$4.75 per acre from the sulfur dusting. The highest profit on any farm was \$11.86 per acre. Twenty-four 1-acre field plots were dusted with sulfur in 1935. An average of 5.7 applications were needed as compared with 3.3 applications in the large-scale experiments. The average gain in yield on the 1-acre plots was 127.8 lb. of seed cotton per acre and the average profit was \$1.40 per acre, as compared with 167.5 lb. gain and an average profit of \$4.75 per acre from dusting on the large-scale tests."

Adelges cooleyi Gillette (Hemiptera, Adelgidae) of the Douglas fir in Britain: Completion of its life cycle, A. E. CAMERON (*Ann. Appl. Biol.*, 23 (1936), No. 3, pp. 585-605, pl. 1, figs. 3).—Studies of *A. cooleyi*, a pest of Sitka spruce, the primary host, and Douglas fir, the secondary host, on the latter of which it has been known in Britain since 1913, are reported. Hitherto its life cycle in Britain has been regarded as incomplete because of the non-viability of generation I (sexuales) on Sitka spruce and consequent absence of the subsequent generation II (fundatrix vera) and generation III (gallicolae). Both of these generations have been discovered for the first time in Britain and their development followed.

The common rustic moth *Apamea* (*Hadena*) *secalis* L. attacking winter cereals, F. R. PETHERBRIDGE and I. THOMAS (*Ann. Appl. Biol.*, 23 (1936), No. 3, pp. 649-652).—Observations of the damage to winter cereals by the larvae of *A. secalis* are reported.

Damage to panicles of *Alopecurus pratensis* L. by *Apamea secalis* L., H. F. BARNES and S. P. MEROKE (*Ann. Appl. Biol.*, 23 (1936), No. 3, pp. 653-657, pl. 1, fig. 1).—A brief description is given of the moth and caterpillar stages of *A. secalis*, above noted, together with notes on its geographical distribution, life history, host plants, and economic importance. Its normal damage is due to the withering and death of the stems of the grasses owing to the caterpillars feeding within the sheaths.

Codling moth control with lead arsenate substitutes, S. W. HARMAN and T. W. REED (*Jour. Econ. Ent.*, 30 (1937), No. 1, pp. 82-86).—The constant demand for lead arsenate substitutes to avoid the residue problem led the New York State Experiment Station to continue field tests with the more promising insecticides (E. S. R., 73, pp. 75, 651). Of the substitutes now available, calcium

arsenate used judiciously and certain of the fixed nicotine sprays have met with most success in New York State.

Observations on poison baits for corn ear worm control, L. P. DITMAN (*Jour. Econ. Ent.*, 30 (1937), No. 1, pp. 116-118).—This contribution is based upon work reported in Maryland Experiment Station Bulletin 399 (E. S. R., 76, p. 831).

Seasonal availability of food plants of two species of *Heliothis* in eastern Georgia, G. W. BARBER (*Jour. Econ. Ent.*, 30 (1937), No. 1, pp. 150-158, fig. 1).—In the southeastern coastal plain within a radius of 50 miles of Savannah, Ga., the larvae of the corn earworm were found to feed on 11 cultivated and 7 wild plants. Those of the tobacco budworm attacked 2 cultivated and 14 wild plants.

The tomato pin worm (*Gnorimoschema lycopersicella* Busck), C. A. THOMAS (*Pennsylvania Sta. Bul.* 337 (1936), pp. 15, figs. 3).—This is a more extended account of studies of the tomato pinworm in Pennsylvania than that previously noted (E. S. R., 75, p. 519).

Upon hatching out from eggs deposited by the moths on the tomato leaves and fruit, the larvae mine into the leaves, stem, and fruit, distorting the leaves and reducing the market value of the fruit. They feed in the leaf mines until full grown, then drop to the ground and pupate in a light cocoon under clods or rubbish. The tomato pinworm also attacks the leaves of potato, eggplant, and horsetail, but prefers tomato. It will not feed on greenhouse flowering plants.

The larvae are attacked by several parasites, but so far these have not been abundant enough to be of value. For artificial control, all or combinations of the following measures are said to help materially in reducing the numbers, or even in eradicating them, namely, rotation of crops, clean seedlings, leaf destruction, cleaning up between crops, field control by burning of plant remains and fall plowing, and insecticide treatments. It is pointed out that for the best results one tomato crop during a winter should be omitted if the pinworm is a problem in the locality, and that a successful outcome is dependent upon the cooperative effort of all growers.

A list of 27 references to the literature is included.

The Cotoneaster webworm, *Cremona cotoneaster* Busck, J. R. ROAF, R. E. DIMICK, and D. C. MORE (*Jour. Econ. Ent.*, 30 (1937), No. 1, pp. 134-136).—An account is given of the life history, effect upon the host, and control of this new species of gelechiid moth attacking the ornamental shrub *Cotoneaster horizontalis*, as observed by the Oregon Experiment Station at Portland and Corvallis in 1933 and 1934. The webworm is readily controlled by either contact or poison sprays such as lead arsenate, nicotine sulfate, and a rotenone-bearing dust. Thorough coverage and proper timing are important. The habit of the caterpillars of feeding upon either the upper or lower surfaces of the leaves necessitates a spray or dust coverage on both sides of the foliage. Also, the habit of the caterpillars of retreating into the refuge bases upon the slightest disturbance requires that the under sides of the branches be thoroughly covered when a nicotine sulfate spray is used.

Effect of moisture on emergence of the ragweed borer *Epiblema strenuana* Walker and its parasites, P. L. RICE (*Jour. Econ. Ent.*, 30 (1937), No. 1, pp. 108-115, figs. 4).—Contributing further from the Delaware Experiment Station (E. S. R., 73, p. 653; 76, p. 823), reference is made to an experiment conducted during 1936, in which two lots of approximately 20 larvae each were exposed to each of 19 different moisture treatments.

"An adult emergence of 100 percent resulted from the lots of insects which were soaked for 1 min. at weekly intervals throughout the season, while no

adults were produced in those lots which received no contact moisture or were not wet until very late in the season. The time and the number of wettings proved to be important factors in emergence. A marked reduction in the percentage of adults produced resulted when soaking of the insects was discontinued before the first of June or when this treatment was not started until July 1. The percentage of adults which emerged after a single soaking treatment applied during the first part of June (the time when ragweed borer pupation normally takes place) was twice as great as the percentages resulting from single treatments applied 3 weeks earlier or 3 weeks later. Transformation to the adult stage was delayed when contact moisture applications were started late. The minimum number of 1-min. wettings necessary to produce a high percentage of adult emergence was not determined. It is apparent, however, that several would be required. The maximum effect produced from one soaking was a 50-percent transformation to the adult stage.

"High humidity alone did not induce normal emergence. Only 1 insect out of the 41 periodically exposed to saturated humidity attained the adult stage. For the most part, lack of contact moisture arrests the development of the ragweed borer in the larval stage. More than 95 percent of the borers which failed to attain maturity died as full-grown larvae. Apparently, contact moisture influences development of the larval parasites of the ragweed borer. Definite conclusions in this particular cannot be drawn from the data presented."

Controlling borers of fruit, forest, and shade trees, L. HASEMAN (*Missouri Sta. Bul.* 373 (1936), pp. 24, figs. 13).—A practical discussion of methods for controlling borer enemies of fruit, forest, and shade trees.

Laboratory propagation of *Compsilura concinnata* Meigen, R. T. WEBBER (*Jour. Econ. Ent.*, 30 (1937), No. 1, pp. 144-149).—The tachinid parasite *C. concinnata*, one of the most important dipterans to be imported into the United States, has three or four generations a year and passes the winter as an immature larva in various species of lepidopterous pupae. The progeny of the second and third generations may either issue or overwinter. The need of a means for supplying the parasite in large numbers at the proper time led to its laboratory propagation, which has made possible the shipment of puparia from 2 to 4 weeks earlier in the spring and later in the summer than would be possible from field-collected material. Parasitization has been accomplished by individual handling, which has proved more dependable than any other method. Reproduction is possible on a large number of common host species, and populations can be built up easily during the season. The difficulty of insuring an abundance of overwintering material for liberation purposes was overcome by forcing the emergence of the overwintering stock and propagating this under laboratory conditions.

The biology of the chrysanthemum leaf-miner *Phytomyza atricornis* Mg. (Diptera: Agramyzidae), M. COHEN (*Ann. Appl. Biol.*, 23 (1936), No. 3, pp. 612-632, pls. 2, figs. 8).—The synonymy and distribution of *P. atricornis* are first discussed. Its host plants are enumerated, and it is shown that the attacks on chrysanthemums decrease by August, although the flies are still common on other Compositae. A description is given, and comparisons are made of the morphology of the three larval instars, together with a discussion of the feeding of the larva. The puparium and emergence of the adult fly are also described, and an attempt is made to separate the puparia into sexes by measurement. Some degree of natural control is secured by the parasitism of a braconid on which a chalcid is probably hyperparasitic. A table in which the developmental period of *P. atricornis* and the chrysanthemum leaf miner are compared is included.

The biology of the apple curculio (*Tachypterellus quadrigibbus* Say), O. H. HAMMER (*New York State Sta. Tech. Bul.* 240 (1936), pp. 50, figs. 17).—Investigations of the biology and habits of the apple curculio that have been in progress since 1930 in the Lake Champlain fruit district in New York (E. S. R., 69, p. 246; 71, p. 355), where the insect is an important pest of apples, are reported upon. While it is generally distributed in the State wherever its native host plants (*Orataegus* spp. and wild crab apples) are found in abundance, it has become of economic importance only in the northeastern part.

Its injury to apple crops is caused by the early season feeding and oviposition activities of the overwintered adults and by the late season feeding of the new brood beetles. A marked preference has been shown for certain commercial apple varieties, although in the Champlain Valley none is immune to attack.

"There is only one brood of the apple curculio each year, and all development from egg to adult occurs inside the fruit. The insect passes the winter in the beetle stage, hibernating under leaves and other debris on the ground. Results of extensive hibernation studies indicate that most of the beetles overwinter under the trees which they infested the preceding summer. Emergence from hibernation begins in early May, and egg laying begins in late May or early June. The overwintered beetles die during the last week in June and the first 2 weeks in July. In general, the incubation period requires 6 days, larval development 19 to 20 days, and pupation 6 to 7 days.

"The new brood beetles begin to emerge from June drops during the second week in July. Emergence from growing apples, of which there is considerable, begins in early September. A few adults enter hibernating quarters in early August, and by September 30 they are practically all in hibernation.

"Studies of the dispersal of the apple curculio showed that certain environmental conditions are conducive to considerable spring migration. Data were obtained to show that the overwintered adults may travel more than 0.25 mile."

Seven species of insects have been found to be parasitic on the immature forms of the apple curculio in the Champlain Valley, namely, *Eurytoma tylodermatis* Ashm., *Entedon tachypterelli* Gahan, *Habrocytus piercei* Cwfd., *Zatropis incertus* Ashm., *Microbracon tachypteri* Mues., *M. mellitor* Say, and *Triaspis curculionis* Fitch. During the 5 yr. these studies were in progress, the maximum parasitism was 25 percent and the minimum 4 percent.

Parasites and predators of the Mexican bean beetle in the United States, N. F. HOWARD and B. J. LANDIS (*U. S. Dept. Agr. Circ.* 418 (1936), pp. 12, figs. 3).—The natural enemies of the Mexican bean beetle, termed *Epilachna varivestis* (*corrupta*) Muls. by Chapin (E. S. R., 75, p. 224), that have come to attention during the course of studies since its spread through the intensively cultivated areas of the United States are briefly considered. The spread of the pest is said to have continued practically unimpeded by these enemies.

Studies on the larvae of the native elm bark beetle, B. J. KASTON and D. S. RIEGS (*Jour. Econ. Ent.*, 30 (1937), No. 1, pp. 98-108, figs. 7).—In this contribution from the Connecticut [New Haven] Experiment Station the authors report upon the number of instars of the native elm bark beetle. While it was not found possible to determine the number of instars by measuring the head capsules of mixed lots of larvae taken at random from various localities in the field, if the measurements are considered separately by families the evidence indicates that some larvae of the *Hylurgopinus rufipes* go through six instars and some through five.

"A special device is described which allowed the daily observation of larvae reared from hatching to pupation. In this way the exact number of instars

and duration of stadia were obtained for each larva. Six, 7, and perhaps 8 instars appear to be the usual number under these conditions, though in 1 family 9 to 12 occurred. There is a positive correlation between the number of instars and the duration of the entire larval period. The rate of tunneling was found to be quite variable with different larvae. Accompanying each ecdysis there is a period of almost a day during which the larva does not feed, and preceding pupation a period of about 3.5 days during which the tunnel is not lengthened."

Damage to wheat by *Helophorus nubilus* F., F. R. PETHERBRIDGE and I. THOMAS (*Ann. Appl. Biol.*, 23 (1936), No. 3, pp. 640-648, pl. 1, figs. 3).—The beetle *H. nubilus* is recorded for the first time as a serious pest of wheat in East Anglia, slight injury having been recorded in 1922 and 1923. Observations made in a number of widely separated fields showed that the intensity of attack varies with the previous cropping, and that a serious attack occurs most frequently after ryegrass and clover.

Repellents for Japanese beetle, H. G. GUY and J. B. SCHMITT (*Jour. Econ. Ent.*, 30 (1937), No. 1, pp. 81-82).—A brief report is made of a limited field experiment at the Delaware Experiment Station undertaken in 1936 in which comparison was made of the repellent action of derris (at 3 lb.) plus various stickers, tetramethyl thiuram disulfide and tetramethyl thiuram monosulfide (at 4 lb.), and hydrated lime (at 20 lb. per 100 gal.). The results indicate that either tetramethyl thiuram disulfide or derris plus a rosin-type sticker offer considerable promise as Japanese beetle repellents.

The sweetpotato weevil and how to control it, K. L. COCKERHAM (*U. S. Dept. Agr. Leaflet 121* (1937), pp. 6, figs. 4).—A practical summary of information.

Studies on European foul brood of bees.—II, The production of the disease experimentally, H. L. A. TARE (*Ann. Appl. Biol.*, 23 (1936), No. 3, pp. 558-584, pls. 3).—In this second contribution (*E. S. R.*, 75, p. 385) the results of a number of production experiments with European foulbrood are reported upon.

Attempts to cause disease by feeding the bees or larvae (without starving them) relatively large numbers of *Streptococcus apis* and *Bacillus alvei* organisms have as yet proved unsuccessful. "Whether this is due to the fact that these bacteria become attenuated with respect to virulence by culturing them on artificial media, or that decomposing brood acts as a vehicle and that the relative inoculum is greater by this method, remains to be determined.

"The failure to produce 'European foulbrood' by feeding sterile Pasteur-Chamberland L 2 or L 3 filtrates prepared from naturally infected larvae to the bees or larvae of healthy nuclei, either with or without bacteria, may be taken as strong evidence in support of the view that a filtrable virus is in no way implicated as an etiological agent in this type of disease. This conclusion is strengthened by the success which has attended the use of pure cultures of the bacteria associated with this disease employing the 'starved larvae' technic described. The introduction of queen bees from nuclei affected with European foulbrood into healthy queenless nuclei has not caused any transmission of the disease under the conditions of the experiments.

"Two species of *S. apis* Maassen have been isolated from affected larvae taken from several different cases of European foulbrood; one of these hydrolyzes both casein and gelatin, the other does not. In other respects these species appear to be identical."

It is concluded from this and earlier work that so-called European foulbrood may not be a single disease with one well-defined etiological agent as is

American foulbrood but is, perhaps, a nonspecific, mixed bacterial infection of the brood of bees, especially of the brood of weak colonies. However, this conclusion must be regarded as temporary pending further investigation.

A list is given of 22 references to the literature.

Poisoning of honeybees by rotenone-derris dusts, R. S. FILMER (*Jour. Econ. Ent.*, 30 (1937), No. 1, pp. 75-77).—Tests conducted by the New Jersey Experiment Stations, here briefly reported, indicate that rotenone dusts are as toxic to honeybees as the arsenical dusts, and that the use of rotenone-derris dusts on agricultural crops may be another serious source of poisoning to honeybees.

On the occurrence in England of the pear fruit saw-fly *Hoplocampa brevis* Klug., I. THOMAS (*Ann. Appl. Biol.*, 23 (1936), No. 3, pp. 633-639, pl. 1, figs. 3).—Although *H. brevis* has been a serious enemy of pears in some continental countries, it is recorded for the first time as a source of injury in England, having been found attacking pears in two gardens in Cambridge. Brief reference is made to a preliminary study of its biology, with descriptions of its immature stages.

Further experiments on the control of the hop red spider mite *Tetranychus telarius* L., S. G. JARY (*Ann. Appl. Biol.*, 23 (1936), No. 3, pp. 606-611).—In further small-scale experiments with a number of spray fluids to combat the common red spider on hops (*E. S. R.*, 74, p. 675), "lime sulfur at a concentration of 1:80 proved very toxic to the mites, but a second application had to be made to deal with those which hatched subsequently from eggs. Emulsions of a 'water white' petroleum oil at 2- and 1-percent concentrations were very toxic to the mites but caused marked edema. Whale oil-potash soap at 1- and 0.5-percent concentration; cottonseed oil emulsion, 6 pt. of oil per 100 gal. of wash; derris extracts of 0.005 percent rotenone and 0.002 percent rotenone content; and a pyrethrum extract of 0.0025-percent content of pyrethrins I and II were all without appreciable toxic effect upon the mites. Lime-sulfur at 1:80, to which a wetter of the sulfonated loral type was added, proved successful in the field for the control of *T. telarius* on hops. No injury to the plants resulted from the use of bordeaux mixture on the same plants."

ANIMAL PRODUCTION

Feeds and feeding, F. B. MORRISON (*Ithaca, N. Y.: Morrison Pub. Co., 1936*, 20. ed., pp. VI+1050, pls. 95, figs. 4).—The twentieth edition of this well-known text (*E. S. R.*, 48, p. 680) retains essentially the same arrangement as earlier editions, but has been entirely rewritten and considerably enlarged. The extensive appendix tables have been revised, and all information on the average composition and the content of the digestible nutrients and mineral and fertilizing constituents of important American feeding stuffs brought together into a single complete and convenient table.

[Investigations with livestock in Florida], A. L. SHEALY, W. M. HENLEY, W. M. NEAL, R. B. BECKER, O. D. ABBOTT, R. W. KIDDER, L. O. GRATZ, W. F. WARD, W. G. KIRK, N. R. MEERHOF, E. F. STANTON, and M. W. EMMEL (*Florida Sta. Rpt. 1936*, pp. 50, 51, 52, 54-56, 57, 70, 138, 139, 143, 144, 145, 146, 155, 156, 158-161, fig. 1).—The results obtained in tests with beef cattle are reported on the use of purebred sires with native cows for grading up herds of cattle; dried grapefruit refuse and fresh cannery run refuse for steers; the efficiency of the trench silo for preservation of forage crops as measured by utilization of the nutrients of the silage by cattle; beef and dual-purpose cattle investigations at the Everglades Substation; the feeding value of sorghum silage,

peanut hay, and cottonseed hulls as roughages in fattening steers at the North Florida Substation; and beef and dual-purpose cattle studies at the West Central Florida Substation.

Swine studies yielded results on a comparison of Spanish peanuts and other grazing crops with dry-lot feeding for pork production, fattening fall pigs for spring market, deficiencies of peanuts when used as a basal ration for swine; and comparisons of gains made by swine on various grazing crops, and fattening fall pigs for the spring market at the North Florida Substation.

A comparison of the adaptability of Columbia and native sheep was made at the North Florida Substation.

In tests with poultry, information was obtained on lecithin synthesis in hens on a vitamin A- and lipoid-free diet; a comparative study of corn and liquid milk v. a grain and mash ration in feeding for egg production; a comparative study of the value of meat scrap, fish meal, and milk solids as sources of protein for egg production; lights v. no lights for egg production on Single Comb White Leghorn pullets and hens; and at the West Central Florida Substation on the use of peanuts and peanut products in rearing turkeys; confinement v. range rearing of chicks; importance of range rotation in poultry production; egg production and mortality of pullets reared under confinement v. range conditions; comparative study of the value of milk solids, ground peanuts with hulls, meat meal, and fish meal in fattening broilers and fryers; and all-night lights v. no lights on Single Comb White Leghorns.

[Investigations with livestock in Georgia] (*Georgia Coastal Plain Sta. Bul. 26 (1936), pp. 38-59, figs. 3*).—Continuing pasture investigations (E. S. R., 75, p. 238), data are reported on the returns secured by beef cattle from both lowland and upland permanent pastures, and various temporary grazing crops including kudzu, *Lespedeza sericea*, oats followed by common lespedeza, Austrian winter peas, hairy vetch, and oats followed by Sudan grass, soybeans, and cattail millet. Beef cattle studies gave information on the production of veal calves and feeder calves, wintering feeder calves, rations for fattening steers, improvement of stock through the use of purebred bulls, and use of a trench silo. Results are noted on the feeding and management of spring and fall litters of pigs.

[Investigations with livestock in Oklahoma] (*Oklahoma Sta. [Blen.] Rpt. 1935-36, pp. 69, 70, 77-97, 141-163, figs. 2*).—Beef cattle studies yielded results on the comparative cost of finishing creep-fed v. noncreep-fed calves, by L. E. Hawkins, O. S. Willham, and B. R. Taylor; a comparison of prairie hay, alfalfa hay, cottonseed hulls, and kafir silage as roughages in the fattening ration of steer calves, by W. L. Blizzard; and the management of native pastures, by Blizzard, Hawkins, and B. F. Kiltz.

Swine studies reported include the value of grinding wheat and kafir for hogs, by C. P. Thompson; the influence of protein intake on reproduction, by Thompson and W. McMillan; and inbreeding v. outcrossing in swine production, by W. A. Craft and Willham.

Results of sheep tests are noted on the comparative value of alfalfa hay, prairie hay, and wheat pasture for fattening lambs, by Willham and H. F. Polson; the influence of nutrition on the physiology of reproduction in sheep, by A. E. Darlow and Hawkins; and methods of curing lamb, by J. A. Beall and D. I. Purdy.

Poultry studies gave results on the value of dried grasshoppers in turkey feeding, by L. Morris; an inexpensive evaporation cooler for preserving eggs over short periods, by R. B. Thompson and C. Roberts; the effect of forcing breeding hens on hatchability, low protein v. high protein for egg production,

and the influence of fiber in the ration of chicks, by R. Penquite; capon production from low cost chicks, by Penquite and Roberts; the influence of time of hatching on young and adult characteristics, by Morris and Thompson; soybeans for laying hens, and feeding for egg yolk color, both by Thompson; the incidence and prevention of perosis and the influence of variety, dam, and sex on weight and feathering of broilers, both by Penquite and V. G. Heller; crossbreeding studies, by R. G. Jaap and Morris; and feed and egg costs since 1929, by F. Z. Beanblossom.

Nutrition studies gave results on the hair loss in albino rats due to gossypol, and various supplements to cottonseed meal for laboratory animals, both by W. D. Gallup and R. Reder.

[Livestock investigations in Pennsylvania] (*Pennsylvania Sta. Bul. 336 (1936)*, pp. 23-25, 26, 35-37, fig. 1).—Results of experiments with livestock are reported on digestion coefficients of feeds for cows and sheep, by E. B. Forbes et al.; the utilization of energy-producing nutriment and protein as affected by individual nutrient deficiencies (the effects of the plane of protein intake), by Forbes, R. W. Swift, A. Black, and O. J. Kahlenberg; hothouse lamb production, by W. L. Henning, P. T. Zeigler, and P. C. MacKenzie; curing pork on the farm, by R. C. Miller and Zeigler; and sweetclover and rape for swine, by T. B. Keith and M. A. McCarty.

Reports of poultry tests include factors affecting quality in eggs, by J. E. Hunter, D. R. Marble, and W. J. Rudy; the relation of nutrition to perosis in poultry, by Hunter and H. C. Knandel; the nutrition of turkeys, by Marble and Hunter; breeding for increased livability, by Marble; and the propagation of ring-necked pheasants, by E. W. Callenbach, Hunter, and R. R. Murphy.

[Livestock investigations in South Carolina] (*South Carolina Sta. Rpt. 1936*, pp. 51-54, 61, 69-72).—Results of experiments under the leadership of E. D. Godbey, L. V. Starkey, E. D. Kyzer, and T. M. Clyburn are briefly reported on methods of feeding cottonseed meal and hulls to fattening steers, the effect of the ration on the quality of beef produced, flax husks v. cottonseed hulls in the ration for wintering beef cattle, rye v. sorghum silage for wintering yearling steers, creep-feeding beef calves, the effect of various treatments on the beef-producing capacity of Coastal Plains pastures, a comparison of summer forage crops for fattening hogs, protein supplements for fattening hogs when grazed on rye forage, the inheritance of the early lambing character, and breed performance in early spring lamb production.

Poultry studies by R. C. Ringrose, C. L. Morgan, and J. H. Mitchell gave results on factors affecting the physical quality of eggs, and the balance between intake and outgo of certain elements in the nutrition of the hen.

[Investigations with livestock in South Dakota] (*South Dakota Rpt. 1936*, pp. 11, 12, 13, 14, 34-37, 38-43).—Information obtained in a test on the value of protein supplements for fattening beef steers, by J. W. Wilson, is reported.

From swine tests results are noted on the use of proso for fattening pigs, the feeding value of low-grade barley, and rations for spring pigs after weaning, all by Wilson.

Poultry studies yielded data on the value of corn, oats, and millet grains in poultry rations; alfalfa leaf meal as a vitamin A supplement to red proso millet and amber cane; the relative values of common grain varieties and their effects upon egg quality and poultry carcass quality; ground wheat as a substitute for bran and middlings; the utilization of corn, wheat, oats, and barley in turkey rations; turkey egg hatchability; and the practicability of caponizing cockerels in South Dakota, all by W. E. Poley.

[Experiments with livestock in Utah] (*Utah Sta. Bul.* 276 (1936), pp. 11-19, figs. 3).—Tests with beef cattle under the leadership of E. J. Maynard, H. H. Smith, J. E. Greaves, R. J. Becraft, and L. A. Stoddart gave information on the influence of calcium-phosphorus ratios on the rate and economy of gain in fattening cattle, the occurrence of phosphorus deficiency as the cause of low gain in summer range cattle, and phosphorus supplements for sugar beet byproducts rations.

Sheep studies reported include the use of sugar beet molasses and corn silage in lamb rations, and corn and cottonseed cake as supplements for wintering sheep on desert range, both by Maynard and A. O. Esplin; and the effect of locality and management on the production and shrinkage of wool, by Esplin.

From swine studies the relative values of tankage, skim milk powder, and semisolid skim milk proteins for fattening swine when fed with ground barley or ground wheat in dry lot and on alfalfa pasture are reported by Smith and Maynard.

Poultry studies gave results on the desirability of forced summer molt in Leghorn hens, optimum levels of animal protein supplement in the laying ration, and the comparative values of soft white wheat v. hard red wheat and barley v. corn for hens, and the costs of feeding turkeys, all by B. Alder.

[Livestock investigations in Wyoming] (*Wyoming Sta. Rpt.* 1936, pp. 7, 8, 9, 11, 21, 22, 24, 26, 28, 29).—Results are noted from studies with sheep on the wool production and market value of lambs resulting from crossing grade fine wool ewes with purebred rams of different breeds; a comparison of alfalfa, Sudan grass, and crested wheatgrass hays in the winter ration of lambs at the Gillette Substation; lamb feeding tests at the Torrington Substation; and the carrying capacity of sweetclover pasture for lambs and ewes, and beet pulp and beet tops in the lamb ration, both at the Worland Substation.

Other livestock studies reported include calcium and phosphorus supplements for beef cattle at the main station, and a comparison of grain rations for hogs at the Lyman Substation.

Poultry studies yielded information on the relation of pauses in winter egg production to the number and size of eggs produced, the use of rye in the chick ration, the use of soybean meal as a partial substitute for meat meal in the chick ration, the relation of the shape of roosts to breastbone deformity in turkeys, and cod-liver oil, alfalfa meal, and long alfalfa as supplements to a basal ration for pullets. Chemical studies gave information on the calcium and phosphorus content of Russian-thistles, sagebrush, willow leaves, grasses, rushes, and sedges.

[Livestock investigations at the Wyoming State experiment farms] (*Wyoming Sta. Bul.* 219 (1937), pp. 20, 24, 26, 27, 33, 34, 39, 40, 43, 45).—Sheep studies are reported from the Gillette Substation on the value of Sudan grass and alfalfa in home-grown rations for lambs, from the Sheridan Substation on a comparison of crested wheatgrass and native grass pasture for sheep, and from the Worland Substation on the returns secured from grazing sheep on alfalfa and on an improved permanent grass pasture, and self-feeding v. hand-feeding of concentrates to lambs in relation to death losses from heavy concentrate rations. Swine tests are reported from the Lyman Substation on a straight barley ration v. a barley (60) wheat (40) mixture for fattening pigs, and the value of skim milk as a supplement to a mixture of barley and oats, and from the Sheridan Substation on pasture feeding v. dry-lot feeding for fattening swine. Studies in progress at the Torrington Substation include the use of beet byproducts and soybean meal for fattening rations

for steers, feeding lambs entirely in panels, dipping lambs for ticks, and experiments with poultry on lights for egg production, milk for growing chicks, and vitamin supplements for laying hens.

U. S. graded and stamped meat (*U. S. Dept. Agr. Leaflet 122 (1936), pp. 7, figs. 9*).—This is a brief description of the methods employed in grading and stamping meats under the Government meat inspection service, with a list of official grades for beef, lamb and mutton, and veal.

The utilization of energy producing nutriment and protein as affected by sodium deficiency, O. J. KAHLENBERG, A. BLACK, and E. B. FORBES (*Jour. Nutr.*, 13 (1937), No. 1, pp. 97–108, fig. 1).—Continuing earlier work⁶ the Pennsylvania Experiment Station has compared a sodium-deficient diet (0.007 percent of sodium) and a sodium-supplemented diet (0.502 percent of sodium) by means of a 10-week growth, metabolism, and body analysis study with 12 carefully selected pairs of young albino rats, with feed intake carefully controlled by the paired method.

No significant differences were noted between the two groups in the digestibility of protein, digestibility or metabolizability of the energy-producing nutrients, or body moisture content. The sodium-deficient ration unfavorably affected the appetite, the increase in weight, the storage of energy, and the synthesis of fat and protein, and resulted in significantly higher heat loss. Animals on the supplemented diet stored a larger amount of energy as fat and also stored decidedly more sodium in their bodies than pair mates on the deficient diet. At the same level of feed intake the supplemented diets supported average gains of 0.9 g per rat daily, which was approximately double that secured on the deficient diet.

The response of rats, chicks, and turkey poults to crystalline vitamin G (flavin), S. LEPKOVSKY and T. H. JUKES (*Jour. Nutr.*, 12 (1936), No. 5, pp. 515–526, figs. 6).—In experiments at the California Experiment Station young rats, chicks, and turkey poults were fed on highly purified synthetic basal diets adequate in all respects except vitamin G (flavine). The rats fed on such diets ceased to grow and developed a type of dermatitis adjudged as definitely different from that due to vitamin B₂ deficiency (E. S. R., 72, p. 282). Later symptoms were loss of weight, gastro-intestinal disturbances, diarrhea, and finally death. The addition of from 10 to 20 μ g (micrograms) of crystalline vitamin G to the daily diet following the appearance of dermatitis and diarrhea caused immediate improvement and a return to normal appearance in 20 days, although diarrhea frequently persisted and growth was irregular. The vitamin G deficiency in chicks was marked by slow growth, diarrhea, emaciation, and poor utilization of feed, but without evidence of a dermatitis. The addition of 2 mg of lactoflavine per 100 g of diet permitted fair growth and increased the efficiency of feed utilization. Vitamin G deficiency in turkey poults resulted in an acute dermatitis in spite of an abundance of the "filtrate factor" (E. S. R., 75, p. 681) which prevents dermatitis in chicks. Other symptoms in the poults were similar to those observed in chicks. The addition of 2 mg of lactoflavine per 100 g of ration prevented the occurrence of dermatitis and permitted rapid growth. These results are discussed in relation to previous investigations of the vitamin B complex.

The relative vitamin G content of alfalfa meal, H. S. WILGUS, JR., L. C. NORRIS, and G. F. HEUSER (*Poultry Sci.*, 15 (1936), No. 6, pp. 446–453).—Employing the method of assay as previously noted (E. S. R., 74, p. 682), the

⁶The utilization of energy producing nutriment and protein as affected by individual nutrient deficiencies.—III, The effects of protein intake. E. B. Forbes, R. W. Swift, A. Black, and O. J. Kahlenberg. *Jour. Nutr.*, 10 (1935), No. 5, pp. 461–479.

[New York] Cornell Experiment Station has determined the vitamin G potency of numerous samples of alfalfa meal, representing varying stages of maturity, curing conditions, and market grades, and has calculated the degree of correlation between the vitamin G potency and grade, protein, ether extract, and fiber analyses.

The average growth-promoting vitamin G content of sun cured and artificially dried alfalfa meals averaged approximately 60 percent and 85 percent, respectively, of that in dried skim milk, although considerable variation occurred in both types of meals, particularly the latter. Neither the percentage of leafy material, protein, ether extract, nor fiber in the meal was sufficiently correlated with vitamin G to establish them as reliable measures of vitamin G potency. In general, meals having a high percentage of leaf, protein, and ether extract and a low fiber content should tend to have a high vitamin G potency.

Factors which may affect the hardness of cottonseed cake, G. S. FRAPS and C. D. MARRS (*Texas Sta. Bul. 534 (1936), pp. 27, figs. 2*).—Continuing the studies on the hardness of cottonseed cake (*E. S. R., 75, p. 236*), certain factors in the composition and manufacture of the cake have been investigated in relation to the hardness of the product. Specimens from a single slab of cottonseed cake varied from 2,600 to 3,500 lb. in crushing strength, and no constant regions of hardness or softness were evident, hard spots and soft spots occurring in both the central and end portions of the slab. No definite relations were found between the chemical composition and hardness of the cake, although the fat content seemed to exert a slight influence in this respect. A pronounced and rapid change of moisture content of the cake (either an increase or a decrease) caused a lowering of the crushing strength. Unpressed meats of high moisture content and the use of relatively high temperatures in the press boxes each seemed conducive to soft waxy cake. Storage in a dry place for approximately 2 yr. did not increase the hardness of the product. The crushing test, as previously noted, was found to be a satisfactory measure of hardness, but a modified Brinell, schleroscope, abrasion, and impact tests each proved unsuitable. The rate of application of the crushing load had no apparent effect on the results, but the direction of the application of the testing load and the degree of smoothness of the test specimen each had considerable effect on the apparent hardness of the cake.

The digestibility of perilla meal, hempseed meal, and babassu meal, as determined for ruminants, A. H. FOLGER (*California Sta. Bul. 604 (1937), pp. 8*).—Continuing the study of the feeding value of feeds recently introduced on the market (*E. S. R., 71, p. 822*), the digestibility of the three above-named feeds has been determined in digestion trials with wether sheep. Perilla meal proved fairly palatable, contained deigestible crude protein 34.1 percent and total digestible nutrients 63.8 percent, and tended to solidify in the bag after short storage periods. Hempseed meal proved rather unpalatable, and considerable time was required in accustoming the sheep to it. A digestible crude protein content of 26 percent and a total digestible nutrient content of 43.8 percent was indicated. Babassu meal, readily consumed by the sheep, had a digestible crude protein content of 21.3 percent and a total digestible nutrient content of 79.7 percent.

The feeding of kapok meal was attempted, but it was found impossible to induce the sheep or some dairy cattle to consume a sufficient quantity of this product to permit a digestion trial.

Production and quality of meat from native and grade yearling cattle, E. H. HOSTETLER, J. E. FOSTER, and O. G. HANKINS (*North Carolina Sta. Bul. 307 (1936), pp. 36, figs. 10*).—The studies herein reported were conducted for

the purpose of comparing the offspring of native cows and a native bull with the offspring of native cows and a purebred Hereford bull with respect to the rate and efficiency of gain during the growth and fattening periods and the quality of the meat produced as determined by laboratory, cooking, and palatability tests. The production phase of this study was carried out in the tidewater region of northeastern North Carolina. The experimental animals were wintered as calves on native roughage and cottonseed meal, grazed principally on reeds during the second summer, placed in the fattening pens about November 15 as long yearlings, and finished on a ration of locally grown corn, soybean hay, and cottonseed meal. The grade Hereford animals excelled the native stock in rate of growth at all stages of the trial and, while the former consumed somewhat more feed per head daily, the latter group actually required 13.5 percent more concentrates and 17.4 percent more soybean hay per 100 lb. of gain. On the basis of feed prices used, the cost of gain was \$1.31 per hundredweight cheaper for the grade Herefords than for the native stock.

The various phases of the meat study were carried out in the laboratories of the U. S. Department of Agriculture. As feeder stock, slaughter animals, and dressed carcasses, the grade Herefords consistently graded higher than the native cattle, the 4-yr. average carcass grade being low good and medium, respectively. The grade cattle dressed 0.53 percent higher, were fatter, and produced a higher percentage of edible meat and a lower percentage of bone than the native cattle. In cooking tests rib roasts from the grade cattle showed more loss from drippings, less loss from evaporation, and more total cooking loss than like cuts from native cattle, the average difference being 0.5 percent. Both mechanical tests and palatability tests indicated that the meat from the grade animals was more tender than from the native cattle, but no other significant differences between the two lots were brought out in palatability studies.

The influence of castration on the growth and fattening in cattle, Y. HABU and M. ISHIHARA (*Imp. Zootech. Expt. Sta., Ohiba, Japan, Bul. 32 (1935), pp. 22+14, pls. 14, fig. 1*).—In a study extending over a 480-day rearing and fattening period no significant differences were noted in the weight growth, growth in height at withers, or economy of feed utilization between lots of native Japanese male calves castrated at 6 mo. of age and at 1 yr. of age and normal bulls. The steers castrated at 6 mo. showed almost complete finish at the end of the experiment, whereas the other lots were not completed at that time. Both steer lots gave carcasses of similar marbling and smoothness of the subcutaneous fat layer, and both were markedly superior to the bull carcasses in this respect. Both lots of steers were considered desirable beef type, whereas the bulls developed secondary sex characteristics and were of less desirable type.

Grazing and parasitical studies with cattle and sheep, M. G. SNELL (*Louisiana Sta. Bul. 279 (1936), pp. 38, figs. 6*).—This is a report of a series of grazing tests on permanent pastures established on rich alluvial soil designated as riverfront land. Five pasture areas were used according to the following plan of management and stocking: Lot 1, unimproved, grazed with cattle; lot 2, improved by disking and seeding, grazed with cattle; lot 3, unimproved, grazed with both cattle and sheep; lot 4, unimproved, grazed with sheep; and lot 5, improved as above and grazed with sheep. Five years' results for lots 1 and 2, and 3 years' results for lots 3, 4, and 5 are reported. The average per acre gains for the last 2 yr. of the trial, during which all areas were comparable, were: Lot 1, 225 lb.; lot 2, 335; lot 3, 340; lot 4, 12; and lot 5, 12 lb.; and the average marketable gains, that is, the gains made by calves and lambs,

were lot 1, calves, 151 lb.; lot 2, calves, 203; lot 3, calves and lambs, 219; lot 4, lambs, 12; and lot 5, lambs, 14 lb. These data indicate the marked increase in gains from improving pastures for cattle, the beneficial effect of grazing sheep and cattle together, and the futility of attempting to make economical gains from such pastures with sheep alone.

With regard to parasitic infestation, it is concluded that the plan of grazing cattle and sheep together was a more effective means of controlling intestinal parasites in lambs than biweekly drenching either with a 1-percent solution of bluestone or a solution containing 1 percent each of bluestone and nicotine sulfate at the rate of 1.2 cc per pound of live weight. Moreover, calves grazed in combination with sheep had fewer intestinal parasites than calves grazed in the regular cattle pasture.

The grazing system exerted a pronounced influence on the pasture flora, those grazed with cattle showing a preponderance of Bermuda grass, those grazed with both cattle and sheep showing a comparatively higher percentage of Dallis grass, and those grazed by sheep alone having a higher percentage of broomsedge, which the sheep refused to graze.

Technique of digestibility trials with sheep and its application to rabbits, S. J. WATSON and E. A. HORTON (*Empire Jour. Expt. Agr.*, 4 (1936), No. 13, pp. 25-35, pl. 1).—This contribution from the Agricultural Research Station, Jealott's Hill, Berkshire, presents a detailed description of the technic employed in conducting digestion trials with sheep, including methods of calculating digestion coefficients and the starch and protein equivalents of different feeding stuffs. The question of correcting the coefficient of protein digestibility to account for the metabolic nitrogen in the feces is discussed and reasons are offered in favor of retaining the uncorrected values.

In comparative digestibility trials with sheep and rabbits it is shown that the latter invariably digest fiber much less efficiently than the former. In trials with grasses satisfactory agreement was obtained only in the case of protein digestion, indicating that the values obtained with rabbits cannot be applied to sheep. The desirability of a satisfactory indicator substance for simplified digestibility trials is discussed, although no satisfactory technic for such procedure has been developed by the authors to date.

Fat lamb production: Sheep crossing experiments conducted at Askham Bryan, York, 1930 to 1935, G. C. A. ROBERTSON (*Univ. Leeds and Yorkshire Council Agr. Ed. [Pam.]* 183 [1936], pp. 52, figs. 16).—In a series of crossbreeding experiments with sheep for the production of market lambs, a satisfactory type lamb was produced by crossing Cheviot ewes with Ryeland, Shropshire, Southdown, or Suffolk rams. Practically all lambs in these lots were sufficiently fat to be marketed when weighing just over 70 lb. The Suffolk cross netted a substantially greater profit than Ryeland and Shropshire crosses, while the Southdowns were intermediate in this respect.

In a second series of experiments in which Masham ewes were crossed with Leicester, Oxford, and Suffolk rams it was found necessary to keep such lambs until they were approximately 10 lb. heavier than the former lots in order to fatten them properly for marketing. The Oxford and Suffolk crosses were about equal in net profit returned, both exceeding the Leicester cross.

The nutrition of the bacon pig.—I, The influence of high levels of protein intake on growth, conformation, and quality in the bacon pig, H. E. WOODMAN, R. E. EVANS, E. H. CALLOW, and J. WISHART (*Jour. Agr. Sci. [England]*, 26 (1936), No. 4, pp. 546-619, pl. 1).—In this extensive experiment three different levels of protein feeding have been employed, each level being tested with a lot of 10 carefully selected Large White bacon pigs fed individually

and with a similar lot of pigs fed by the group feeding plan. The high protein concentrates in the rations consisted of various combinations of white-fish meal, meat meal, and soybean oil meal. The ration fed lot 1 in each series contained 12 percent of protein-rich concentrate until the pigs had attained a live weight of 90 lb., 10 percent from 90 to 150 lb., and 5 percent from 150 lb. until slaughtered, while lot-2 rations contained 22, 20, and 15 percent, and lot-3 rations 32, 30, and 25 percent of protein concentrate during these three respective growth stages.

The lower level of protein proved adequate for normal growth in each series, no greater growth rate being attained at the intermediate protein level, while the highest level of protein feeding resulted in a slight depression in rate of growth and a slight increase in the amount of feed required per unit of gain. Slight differences in rate and economy of gain in favor of females over males were also noted. Of particular interest from the standpoint of experimental methods is the fact that the group feeding trials gave results generally supporting the individual feeding trial. However, owing to the relative insensitivity of the group feeding lay-out, it was not possible to show that the effects of different feeding treatments under this plan were statistically significant, whereas differences due to feeding conditions and to sex were statistically significant under the individual feeding plan.

From slaughter tests results are presented on the quality of the carcass, the thickness of back and belly fat, the percentages of fat and lean in various cuts, the composition of certain muscle tissue, the size of the kidneys, and the iodine value of the fat. In general, the different feeding methods had no significant influence on the quality and composition of the carcass. A lengthy discussion of numerous associated factors is presented.

Rations for weanling pigs, L. A. WEAVER (*Missouri Sta. Bul. 576 (1937), pp. 8, fig. 1*).—This is a report of a series of experiments to determine the value of various protein concentrates as supplements to corn in the ration of weanling pigs. The results indicate that pigs fed a corn and tankage ration in dry lot made relatively very poor gains as compared with pigs receiving the same ration and pasture. A ration of corn supplemented with a mixture of liver meal, dried skim milk or buttermilk, and alfalfa meal plus minerals in dry lot proved superior to the corn-tankage ration with pasture, while the latter gave better results than rations of corn and skim milk or corn, tankage, oil meal byproducts, and alfalfa meal in dry lot. A mixture of equal parts of tankage, linseed oil meal, fish meal, liver meal, dried skim milk, and alfalfa meal proved a more efficient supplement to corn than a mixture of three parts tankage, one part linseed oil meal, and one part alfalfa, although the advantage of the former was largely confined to the first 28-day period following weaning. In a final experiment to determine whether the dried skim milk, fish meal, or liver meal was responsible for the advantage noted in previous experiments, any of the three or combinations gave beneficial results, the liver meal proving more efficient than dried skim milk, which in turn was superior to the fish meal.

The use of wood sugar in pig fattening, H. BÜNGER (*Die Verwendung von Holzzucker in der Schweinemast. Berlin: Paul Parey, 1936, pp. [3]+226, figs. 6; also in Landw. Vers. Sta., 126 (1936), No. 1-6, pp. 1-226, figs. 6*).—This publication describes the manufacture of wood sugar under commercial conditions. The wood is treated with concentrated hydrochloric acid, the acid removed by distillation, and the sugar solution concentrated. About 67 kg of carbohydrates are obtained per 100 kg of wood. The hydrochloric acid is recovered along with acetic acid and other valuable byproducts. Normally the sugar sirup is neutralized with lime and fed by mixing with other dry feeding

stuffs. The product has a starch equivalent value of 62.1 kg per 100 kg of dry sugar, ranking it as about equal to cane sugar in nutritive value. Two parts of sugar can be mixed with one part of such feeds as crushed barley or dried potato flakes and stored for several months without deterioration and with little change.

In a series of feeding trials with pigs the starch value of a sugar-potato mixture was equal to that of potatoes alone, and a sugar-barley mixture was only slightly inferior to barley alone. Wood sugar (and wood sugar yeast as a source of protein) are considered potentially important feeding stuffs.

Feeding wood sugar yeast as a source of protein to working horses and the replacement of oats by dried beet slices or potato flakes and wood sugar yeast [trans. title], P. EHRENBURG and H. NIETSCHE (*Landw. Vers. Sta.*, 125 (1936), No. 5-6, pp. 301-339).—Wood sugar yeast, along with dried beet slices or potato flakes as a part of the usual feed for working horses, proved to be a satisfactory substitute for oats in the ration. The wood sugar yeast was unpalatable at first, but this was overcome by adding a small amount of molasses which was later omitted. The crude protein of the yeast had a digestibility of 94.3 percent (82.6 percent for pure protein). The yeast as delivered contained 41.4 percent digestible crude protein (33.3 percent digestible pure protein) and 89.6 percent dry matter.

The usefulness of winter and summer-fall egg yield records as criteria of poultry breeder selection, W. C. THOMPSON and F. P. JEFFREY (*New Jersey Stats. Bul.* 612 (1936), pp. 26, figs. 10).—In conducting this study, the first year egg yield records of 2,028 purebred Single Comb White Leghorn pullets, entered in New Jersey egg-laying contests during a typical year of operation, have been employed. The record year has been divided into three parts, namely, the winter season (October 1 to January 31), the spring season (February 1 to May 31), and the summer-fall season (June 1 to September 22). In comparing the winter egg production and the summer-fall egg production with annual egg yields it is shown that each of these seasonal yields bears a highly significant positive correlation to the annual yield, each being of curvilinear character and expressed by the regression equation $Y=136.24 \log X-30.79$ and $Y=133.22 \log X-31.62$, respectively, in which Y represents the annual and X the seasonal production. However, an insignificant degree of correlation was found to exist between winter yields and summer-fall yields, indicating that fowls inherit precocity or winter production tendency entirely separately from the factor of persistency or summer egg yield tendency. A combination of the winter and summer-fall records also bears a highly significant positive correlation to annual yield. This is a curvilinear relationship expressed by the regression equation $\log Y=0.8367 \log X+0.5653$. A remarkably close correlation was found to exist between the observed yield and computed annual yield by this method. It is concluded that trap-nest records for either the winter period or the summer-fall period may be employed with confidence in the selection of breeding stock and that the combined winter and summer-fall records are highly valuable in this respect, being possibly of somewhat greater accuracy for that purpose than the record of exact egg production performance over the full year.

Selecting poultry breeders by means of winter and summer-fall egg yield results, W. C. THOMPSON and F. P. JEFFREY (*New Jersey Stats. Hints to Poultrymen*, 24 (1936), No. 1, pp. [4]).—This is a popular summary of the above.

Measurements of quantity and quality of egg yield, W. C. THOMPSON, D. PHILPOTT, and H. C. PAGE (*New Jersey Stat. Bul.* 614 (1936), pp. 31, figs. 5).—This is a revision of Bulletin 528 (E. S. R., 66, p. 364) and presents essentially the same conclusions as those previously noted.

The constancy of the albumen index of eggs from individual hens, L. A. WILHELM and V. HELMAN (*U. S. Egg and Poultry Mag.*, 42 (1936), No. 12, pp. 750, 751, 761).—Employing the method for determining the albumin index of eggs previously noted (E. S. R., 76, p. 234), the Washington Experiment Station has studied the constancy of the albumin index for individual hens. In one group all eggs produced during a 30-day period were used, and in a second group all eggs laid during a 14-day period plus eggs collected at intervals during the succeeding weeks were included. For the periods of time and uniform environmental conditions prevailing during this study, hens have the individual characteristic of producing eggs which have a relatively constant albumin index.

Formation of the chalazae in the hen's egg, H. J. ALMQUIST (*Poultry Sci.*, 15 (1936), No. 6, pp. 460, 461).—In this study at the California Experiment Station the author has noted that, in 520 White Leghorn eggs in which both chalazae were normal, the chalaza at the large end of the egg invariably had a clockwise twist and the one at the small end a counterclockwise twist. As an explanation of this condition it is postulated that the egg is invariably located in the uterus small end caudad, that the egg as a whole rotates in a counterclockwise direction, and that the yolk rotates less frequently than its envelopes, thus causing the opposite twists in the mucin strands which comprise the chalaza. This condition, together with the syneresis in the firm albumin, results in these strands shrinking together into a twisted cordlike structure.

The association of certain measures of interior egg quality with hatchability, G. O. HALL and A. VAN WAGENEN (*Poultry Sci.*, 15 (1936), No. 6, pp. 501–506, fig. 1).—The [New York] Cornell Experiment Station has made correlation studies to determine the relation of hatchability of eggs to four measures of interior egg quality, namely, condition of firm albumin, percentage of firm albumin, percentage of outer thin albumin, and yolk index. The condition of firm albumin was found to be the only one of these factors significantly correlated with hatchability. Eggs showing a defective condition of the firm albumin suffered greater embryonic mortality, particularly during the second to the seventh day of incubation, than eggs which were satisfactory in this respect. Although it has not been demonstrated that the condition of firm albumin is a governing factor in hatchability, it appears that because of the existing relationship selection for high hatchability should tend to improve egg quality.

A hatchability study among Ohio hatcheries, G. S. VICKERS (*Poultry Sci.*, 15 (1936), No. 6, pp. 496–500).—In a summary of the 1935 reports from Ohio hatcheries, it is shown that sudden cold spells during the winter invariably cause a drop in hatchability of eggs, starting from 3 to 4 days after the onset of the cold spell and continuing for several days. A rather marked and constant difference in hatchability results was noted between hatcheries in the northern and southern parts of the State in favor of the latter group. These differences were greatest in the late winter and were of small consequence after April 21. The season's average for the highest percentage of hatchability noted each week was 76 and for the lowest 55.4, with the highest occurring in a hatchery in the southern part of the State in most cases.

Rearing chicks from the incubator to the laying pen or fattening crate, F. C. ELFORD and H. S. GUTTERIDGE (*Canada Dept. Agr. Pub.* 531 (1936), pp. 8, fig. 1).—A popular circular discussing methods in brooding and rearing, types

of poultry for market, finishing poultry for marketing, killing and plucking, and selecting the layers.

The distribution and properties of the anti-gizzard-erosion factor required by chicks, H. R. BIRD, O. L. KLINE, C. A. ELVEHJEM, E. B. HART, and J. G. HALPIN (*Jour. Nutr.*, 12 (1936), No. 6, pp. 571-582).—In this investigation at the Wisconsin Experiment Station the results indicate that the dietary factor preventing gizzard erosion in chicks is distinct from the antihemorrhagic factor, confirming the findings of Almquist and Stokstad (*El. S. R.*, 76, p. 88). At variance with these findings, however, the authors have found alfalfa and other leafy plant tissue to be generally unsatisfactory as a source of the anti-gizzard-erosion factor and also that this factor is insoluble in fat solvents. Pork lung, liver, and kidney tissue were found to contain an abundance of the factor, which followed the alkali-soluble, acid-precipitable proteins during fractionation. However, this method of fractionation was unsuccessful when applied to oats, indicating that the factor is not necessarily a part of a protein molecule. Cereals were ranked oats, wheat, and corn in order of the abundance of this factor. The possibility of identity of this factor with certain members of the B complex is briefly discussed.

The state and partition of the calcium and inorganic phosphorus in the serum of the fowl: Effect of growth and ovulation, D. M. GREENBERG, C. E. LARSON, P. B. PEARSON, and B. R. MURMESTER (*Poultry Sci.*, 15 (1936), No. 6, pp. 483-489, fig. 1).—The authors have made a comparative study of the partition of calcium and inorganic phosphorus in the blood serum of $\frac{1}{2}$ - to $5\frac{1}{2}$ -month-old growing chicks and of prelaying and laying hens from 6 to 8 mo. of age. In the growing chicks the total serum calcium remained relatively constant (from 11.3 to 12.9 mg per 100 cc) throughout the period, whereas the total serum inorganic phosphorus progressively decreased (from 10 to 5.5 mg per 100 cc) with increasing age. During the immediate prelaying and laying periods a very marked increase in serum calcium was noted, accompanied by a relatively small increase in the inorganic phosphorus level. The calcium increase was confined almost exclusively to the nondiffusible fraction, with experimental evidence that the calcium-combining capacity of the serum vitellin is sufficiently great to account for the excess nondiffusible calcium.

Some reasons for early sexual maturity including "staginess" of cockerels—its possible control discussed, N. F. WATERS (*U. S. Egg and Poultry Mag.*, 42 (1936), No. 11, pp. 664-668, figs. 6).—This contribution from the Iowa Experiment Station presents data on the growth rates and time of sexual maturity of light and heavy breeds of chickens and for the first and second generations of cross-bred strains. On the average sexual maturity is reached when the bird has attained approximately 90 percent of its mature body weight. Breeding and selecting for early maturing strains result in reducing the average mature size of the stock. Apparently a bird is early maturing sexually because it is small and not a small bird because it is early sexually maturing. The need for a constructive research program in poultry breeding with reference to the quality of market poultry is stressed.

Preliminary studies of a cerebral disorder of young chickens, J. P. DELAPLANE, H. O. STUART, and C. P. HART (*Science*, 84 (1936), No. 2183, pp. 396, 397).—This report from the Rhode Island Experiment Station notes the occurrence of a brain disorder in young chicks in the field under a wide variation of feeding and management practices, breeds, and strains. The faster-growing chicks from 3 to 6 weeks of age seem most susceptible. This disorder shows a close resemblance to that described by Pappenheimer and Goettsch.⁷ Cultural tests indi-

⁷ *Jour. Expt. Med.*, 53 (1931), No. 1, pp. 11-26, pls. 3, figs. 2.

cate that it is not of an infectious nature and is probably of a nutritional type. In controlled experiments with a number of rations only one group on a ration in which corn was the main ingredient developed the typical symptoms and brain lesions. It is believed that some factor or factors in the corn were responsible for or at least contributed to this disorder.

A field condition resembling nutritional encephalomalacia in chicks, E. JUNGHEER (*Science*, 84 (1936), No. 2190, pp. 559, 560).—This contribution from the [Connecticut] Storrs Experiment Station notes the occurrence of a brain disorder in brooder chicks, fed on a number of commercial and home-mixed rations, which is indistinguishable from nutritional encephalomalacia inducible on simplified diets as described by Pappenheimer and Goettsch, and noted above. Comparatively large fast-growing chicks from 14 to 59 days of age are most susceptible. Symptoms of the disorder are discussed. Histological examination of certain organs was necessary to distinguish this field encephalomalacia from other nonmicrobial paralytic disorders in growing chicks.

Chicken vices, D. C. KENNARD (*Ohio Sta. Bimo. Bul.* 184 (1937), pp. 33-39, figs. 2).—The most common causes of feather picking and cannibalism are discussed, and effective prevention and control methods are suggested. Debeaking, i. e., removing the tip of the upper beak, has proved the most satisfactory control procedure. The method whereby the beak tip is removed with comparatively little discomfort to the bird and practically no loss of blood is described.

A study of egg production in Bronze turkeys, S. J. MARSDEN (*Poultry Sci.*, 15 (1936), No. 6, pp. 439-445).—This study, conducted at the U. S. D. A. Range Livestock Experiment Station at Miles City, Mont., was undertaken to obtain information on the egg-laying habits and ability of turkeys. Single egg clutches constituted 37.65 percent and 42.19 percent of all clutches recorded for young hens and older hens, respectively. The average size of all clutches averaged 2.39 eggs and 2.23 eggs for these respective groups. The largest clutch recorded was 19 eggs laid by a young hen. It seems evident that turkeys, when fed and managed for maximum egg production, do not differ significantly from chickens in their laying habits.

Young hens in their first laying season produced an average of 39.9 eggs to May 31 without artificial lighting and 48.9 eggs with artificial lighting starting in February. Hens in their second laying season without artificial lights averaged 27.6 eggs from the beginning of the laying season to May 31, while hens in their third, fourth, and fifth laying seasons with artificial lights in each instance averaged 29.1, 23.7, and 14 eggs, respectively, over a like period. Annual egg production for a flock without artificial lighting averaged 55.8 eggs in 1930 and 59.7 in 1931.

Egg size in relation to growth of Narragansett turkeys, H. M. SCOTT and R. E. PHILLIPS (*Poultry Sci.*, 15 (1936), No. 6, pp. 435-438).—In this study at the Kansas Experiment Station 538 eggs ranging from 67.6 to 100.5 g in weight and representing approximately a normal frequency distribution were used for hatching. Correlating weight of turkeys at 24 weeks of age with egg weight showed a coefficient of correlation of 0.179 ± 0.046 for males and 0.119 ± 0.046 for females. It seems evident that egg weight in no way conditions the mature weight of turkeys, although a high correlation was noted between egg weight and day-old weight of poults.

The protein requirement of Ringnecked pheasant chicks, L. O. NORRIS, L. J. ELMORE, R. C. RINGROSE, and G. BUMP (*Poultry Sci.*, 15 (1936), No. 6, pp. 454-459, fig. 1).—In a series of feeding tests with ring-necked pheasant chicks, the protein content of otherwise adequate rations was varied from 15 to 33 percent. Maximum growth during the first 8 weeks of life was obtained by

feeding a 30 percent protein ration, and excellent growth was obtained from rations containing 21, 24, and 27 percent protein. A 24 percent ration is suggested as one which will give generally satisfactory results without danger of creating partial deficiencies of other essential nutritive elements.

Some elementary concepts in the theory of sampling, W. A. HENDRICKS (*Poultry Sci.*, 51 (1936), No. 6, pp. 462-465).—This contribution from the U. S. D. A. Bureau of Animal Industry discusses some concepts involved in the theory of sampling, with special reference to poultry experiments, and directs attention to the interpretation to be placed on some of the newer developments in the application of statistical technic to agricultural experiments.

DAIRY FARMING—DAIRYING

Dairying in Arizona, W. S. CUNNINGHAM (*Arizona Sta. Bul.* 155 (1937), pp. 27-67, figs. 18).—This deals with the characteristics of the various breeds of dairy cattle, the selection of individual animals, the composition and characteristics of feeds, feeding various classes of dairy animals, balancing rations, and general rules for feeding. Results of feeding experiments comparing hairy Peruvian v. common alfalfa hay and bud-stage v. one-third bloom alfalfa hay for milk production are also presented. No significant differences were found regarding the feeding value of the two varieties tested. A slight difference in favor of the bud-stage hay is reported.

[Investigations with dairy cattle in Florida], R. B. BECKER, W. M. NEAL, A. L. SHEALY, and P. T. D. ARNOLD (*Florida Sta. Rpt.* 1936, pp. 49, 50, 51, 53, 54).—Data obtained in studies with dairy cattle are reported on mineral deficiencies in feeds used in cattle rations, the ensilability of sugarcane and other Florida forage crops, the feeding value of crotalarias, and the digestible coefficients and feeding value of dried grapefruit refuse and dried orange refuse.

[Investigations with dairy cattle and dairy products in Oklahoma] (*Oklahoma Sta. [Bien.] Rpt.* 1935-36, pp. 5-25, 70, 71, 73-75).—Work was continued on most of the research projects previously noted (E. S. R., 73, p. 98), and brief results are presented on "cottonseed meal injury" an incorrect term, by A. H. Kuhlman, E. Weaver, and W. D. Gallup; the comparative value of good prairie hay and alfalfa hay in the dairy ration, by Kuhlman, Weaver, and A. Nalbandov; the digestibility and feeding value of mung bean silage, by Kuhlman, Weaver, Gallup, and Nalbandov; two types of blindness in cattle which are related to vitamin A deficiency, by Kuhlman, Weaver, and Gallup; influence of purebred sires in improving a scrub dairy herd, by P. C. McGilliard and Weaver; effects of cottonseed meal on dairy products, by J. I. Keith, Kuhlman, Weaver, and Gallup; factors involved in the development of oxidized and rancid flavors in milk, by Weaver, E. L. Fouts, Keith, and McGilliard; ionic equilibria in ice cream mixes and the manufacture of cream and Neufchatel cheese, both by Keith, Fouts, and Weaver; and a test for sediment in cream, by Fouts.

[Experiments with dairy cattle and dairy products in Pennsylvania] (*Pennsylvania Sta. Bul.* 336 (1936), pp. 12, 28-30).—Reports of dairy cattle investigations include the value of bonemeal in the ration of milking cows, by S. I. Bechdel; the deficiency of carotene in dairy calf rations containing large amounts of cottonseed meal, by Bechdel and S. R. Skaggs; and the effect of feeding poor quality hay to calves, by Bechdel and R. E. Ward.

In studies with dairy products results are reported on tallowy flavor in milk, by C. D. Dahle; a comparison of glass and paper bottles as containers for milk and dairy products, and standardization of the equipment and procedure for determining curd tension of milk, both by F. J. Doan; the relation

of the fat globule membrane to the whipping ability of ice cream mixes, by Dahle and D. V. Josephson; and vitamins in milk as related to fat content, breed characteristics, and stage of lactation, by N. B. Guerrant.

[Dairy cattle investigations in South Carolina] (*South Carolina Sta. Rpt. 1936, pp. 50, 54-60, fig. 1*).—Results are reported on the response of the individual cow to the milking machine, and various kinds of silage as the only roughage for milking cows, both by E. C. Elting and J. P. LaMaster; and factors affecting the carotene content of feeds grown in South Carolina, by J. H. Mitchell and LaMaster.

[Experiments with dairy cattle and dairy products], T. M. OLSON (*South Dakota Sta. Rpt. 1936, pp. 20, 21-25*).—Results obtained in tests with dairy cattle are reported on the effect of lack of direct sunlight on production and reproduction of dairy cows; a comparison of sweetclover, alfalfa, and Sudan grass pasture under South Dakota conditions; permanent pasture mixtures; variations in calcium and phosphorus content of cows' milk during the lactation period; the relation of vitamin D to the calcium and phosphorus retention of mature lactating cows as shown by balance trials; and a breed comparison in ability to transform and convert the vitamin D of the feed ingested to the milk produced.

Studies with dairy products yielded results on the effect of tankage on the flavor of milk; the relation of the amino nitrogen content to quality of cream and butter; variation in Ca and P content of milk during lactation; the relationship between the lipolytic and proteolytic micro-organisms in butter and the development of specific flavor defects in butter; and the influence of roughage on the vitamin D potency of milk.

[Dairy cattle investigations in Wyoming] (*Wyoming Sta. Rpt. 1936, pp. 8, 18*).—Results are briefly noted on roughage for dairy heifers, the quality of pasture and hay for dairy cows, and comparative milk yields with and without grain on alfalfa hay and irrigated pasture and with alfalfa hay v. native hay.

[Dairy cattle investigations at the Wyoming State experiment farms] (*Wyoming Sta. Bul. 219 (1937), pp. 4, 5, fig. 1*).—Studies at the Afton Substation yielded results on the comparative value of native meadow hay and alfalfa hay for milking cows, the increased milk yield resulting from adding ground barley to a ration of alfalfa hay and pasture, and open sheds v. modern barn stanchions for milking cows.

Milk yield dependent on ration (*Utah Sta. Bul. 276 (1936), p. 11*).—Studies by G. Q. Bateman and G. B. Caine are noted comparing rations of alfalfa hay and pasture and alfalfa hay, corn silage, and pasture for milking cows with an alfalfa hay, ground barley, and pasture ration.

Legume silage for dairy cows, C. C. HAYDEN, A. E. PERKINS, W. E. KRAUSS, C. F. MONROE, and R. G. WASHBURN (*Ohio Sta. Bimo. Bul. 184 (1937), pp. 21-27, fig. 1*).—This report discusses the possibility of ensiling untreated legumes, molasses-treated legumes, and legumes treated with mineral acid (A. I. V. process). Data are presented indicating that the feeding of the acid-treated silage supplemented with ground limestone results in a marked increase of urinary ammonia and a decrease of bicarbonates in the urine, although not to a dangerous extent. This feed proved superior to alfalfa hay in stimulating milk production and in maintaining a desirable carotene concentration in the butterfat during the winter feeding period. The carotene content of the legume plant was preserved nearly intact by this method.

Apparently a legume silage of good feeding value may be prepared by any of the three systems discussed, but only the treatment with acid offers a reliable way of preserving a high percentage of the carotene content of the crop.

The nutritive value of raw and pasteurized milk for calves: The assimilation and retention of nitrogen, phosphorus, and calcium. J. H. BLACKWOOD, S. MORRIS, and N. C. WRIGHT (*Jour. Dairy Res. [London]*, 7 (1936), No. 3, pp. 228-237, fig. 1).—This experiment involved a total of 16 Ayrshire male calves placed on experiment at 10 days of age and fed either raw or pasteurized milk at the rate of 10 percent of their body weight daily. Three series of trials are reported, in the first and third of which calves were fed by the double reversal method over three 24-day experimental periods, while in the second trial the calves were fed on the same diet continuously over a 42-day test period.

As measured by the rate of assimilation and retention of nitrogen, calcium, and phosphorus, no significant differences were found between the two types of milk. It appears that milk is relatively deficient in calcium and to a less extent in phosphorus when used as the sole diet for calves. The including of pasture grass or hay in the ration materially improves the nitrogen: calcium balance. No pathological conditions were encountered.

Nutritional anemia, calcium, phosphorus, and nitrogen balance and bone composition of rats fed raw versus pasteurized milk. H. A. LASBY and L. S. PALMER (*Jour. Dairy Sci.*, 18 (1935), No. 3, Sup., pp. 6).—This supplement presents an authors' correction of the original article (*E. S. R.*, 73, p. 377). Accordingly the last paragraph of the abstract should be changed to read:

Calcium and nitrogen retentions were slightly though not significantly greater on the raw milk. Phosphorus retentions were the same on the two diets. The bones of rats fed raw milk had a higher percentage of ash than those of rats fed pasteurized milk, the difference being statistically but not biologically significant and not explained on the basis of the better growth of the rats receiving the pasteurized milk. The mean calcium and phosphorus contents of the bones of rats on raw milk were slightly but not significantly higher than those on pasteurized milk. The mean calcium and phosphorus contents of the milk were the same before and after pasteurization.

Dairy goats in Missouri. C. W. TURNER, A. C. RAGSDALE, and E. R. GARRISON (*Missouri Sta. Bul.* 375 (1937), pp. 23, figs. 11).—This bulletin consists of a series of questions and answers dealing with the characteristics of the various breeds of dairy goats, breeding, feeding, and management problems concerning the goat herd, and the composition and production of quality milk.

[**Proceedings of the ninth annual State College of Washington Institute of Dairying**] (*Wash. State Col., Inst. Dairying Proc.*, 9 (1936), pp. [3]+144, figs. 9).—The following papers were presented at the meeting held at Pullman, March 2-7, 1936 (*E. S. R.*, 74, p. 90): New Research on the Utilization of Dairy By-products for Poultry Feeding, by V. Heiman (pp. 3, 4); Problems of the Cheese Industry, by L. A. Rogers (pp. 4-12); Trends in Butter Manufacture—Meeting the Consumer's Demand, by M. Mortensen (pp. 12-17); Some Factors Affecting Butter Consumption, by N. S. Golding (pp. 17-23); Hedging Practice—Price—Price Insurance, by H. E. Van Norman (pp. 23-26); Standardization of Butter and the Value of Graphic Chart, by M. Mortensen (pp. 26-35); Physical Defects of Retail Cream, by N. S. Golding (pp. 36-46); The Dairy By-products Problem, by L. A. Rogers (pp. 47-53); Uses of Dairy Products by the Baker, by C. A. McDuffee (pp. 53-57); Practical Pointers on Plant Mechanics, by R. Monahan (pp. 57-59); Three Years of Educational Butter Scoring Work at the State College of Washington, by H. A. Bendixen (pp. 60-63); What Economic System Does Business Want? by R. B. Heflbower (pp. 69-71); The Function of the Laboratory in the Dairy Industry, by L. A. Rogers (pp. 71-79); Plant Engineering Problems in the Manufacture of

Dairy Products, by B. O. Opitz (pp. 79-85); Sodium Alginate Products in Ice Cream and Chocolate Milk, by S. E. Briggs (pp. 85-90); Recent Research Developments in Ice Cream Manufacturing, by D. R. Theophilus (pp. 91-96); Dairy Research of the State College of Washington, by E. V. Ellington (pp. 96-99); Refrigeration of Milk Delivery Units, by M. Matthews, Jr. (pp. 100-108); New Developments in Milk Plant Equipment, by E. N. Muzzy (pp. 108-116); Milk and Citrus Juices, by D. S. Courtney (pp. 117-120); Problems of the Fluid Milk Industry, by L. A. Rogers (pp. 120-129); Artificial Insemination in Dairy Cattle, by T. C. Webster (pp. 129-131); The Herd Test, by E. W. Van Tassell (pp. 131-133); and The Color, Carotene, and Vitamin A Content of Milk as Influenced by the Feed, by R. E. Hodgson (pp. 133-136).

Judging quality in dairy products, P. A. Downs (*Nebraska Sta. Circ. 54* (1937), pp. 44, figs. 11).—This circular presents score cards, outlines methods of procedure, and discusses terms applicable to common defects, for the judging of milk, cream, butter, Cheddar cheese, and ice cream. Suggestions for conducting a dairy products judging contest are offered.

The comparative values of the plate count and the modified methylene-blue reduction test as routine methods for grading milk, A. A. NICHOLS and S. J. EDWARDS (*Jour. Dairy Res.* [London], 7 (1936), No. 3, pp. 258-270, fig. 1).—Based on experimental results as reported, the authors conclude that the results obtained by the modified methylene blue reduction test (1) show reasonable agreement with, and are less variable than, those obtained by the plate count, (2) show as good an agreement with other measures of cleanliness as does the plate count, and (3) are not invalidated by the presence of abnormal milk. Consequently they regard the methylene blue reduction test as having outstanding advantages for the general purpose of classifying milk according to bacterial quality.

Van Oijen modification of the Frost Little plate method: A critical investigation of Van Oijen's test for the bacterial content of milk samples, H. BARKWORTH (*Jour. Dairy Res.* [London], 7 (1936), No. 3, pp. 244-257).—This report is based on a statistical examination of the results obtained on the bacterial content of 31 low-count milk samples (3,000 to 30,000 per cubic centimeter) and 31 high-count milk samples (30,000 to 300,000 per cubic centimeter), each tested in quintuplicate by both the Van Oijen and the standard plate count methods, employing standardized technic as outlined. The former test is shown to be significantly more accurate than the latter, although the average count by the Van Oijen method is 1 to 3 percent log lower than the average plate count. The effect of the size of samples on reproducibility of results is discussed.

A critical study of some of the growth-promoting and growth-inhibiting substances present in brilliant-green bile medium, C. N. STARK and L. R. CURRIS (*Jour. Bact.*, 32 (1936), No. 4, pp. 375-384).—In this report from the [New York] Cornell Experiment Station 0.00133 percent of brilliant green in a 1-percent peptone 1-percent lactose medium completely inhibited growth of all members of the *Escherichia-Aerobacter* group. The addition of 2-percent dried oxgall to this medium materially reduced the toxicity of the brilliant green, permitting the growth of certain cultures which could be responsible for false tests by means of "synergism". Additional protein in the form of 1 cc of sterile milk to 14 cc of the medium permitted growth of even larger numbers of the above cultures and also resulted in growth of some sporulating false test organisms. These findings are regarded as having special significance in the use of brilliant green bile medium to test milk for the presence of the *Escherichia-Aerobacter* group.

Increased growth and gas production by *Escherichia-Aerobacter* organisms in brilliant green bile medium containing sodium formate, C. N. STARK and L. R. CURTIS (*Jour. Bact.*, 32 (1936), No. 4, pp. 385-391).—Continuing the above line of investigation, the addition of 0.5 percent of sodium formate to the brilliant green bile medium resulted in larger numbers and increased growth rate of *Escherichia-Aerobacter* organisms. It caused an earlier production of gas, and the formation of from two to three times as much gas, while failing to influence materially the growth of organisms which may be responsible for false tests.

Hemolytic streptococci in market milk, J. E. SIMMONS (*Jour. Bact.*, 32 (1936), No. 4, pp. 469, 470).—This note from the Oregon Experiment Station reports the isolation of 101 cultures, showing definite evidence of hemolysis, from samples of market milk. Forty-one of these proved to be long chain streptococci, the characteristics of which are described. Most of the organisms could be placed in two large groups having the general characteristics of *Streptococcus mastitidis* and *S. infrequens*.

The vitamin and nitrogen requirements of the lactic acid bacteria, S. ORLA-JENSEN, N. C. OTTE, and A. SNOG-KJÆR (*K. Danske Vidensk. Selsk. Skr., Naturv. og Math. Afd., 9. ser., 6* (1936), No. 5, pp. 52; also in *Zentbl. Bakt. [etc.]*, 2 Abt., 94 (1936), No. 19-23, pp. 434-477).—With regard to the vitamin requirements of lactic acid bacteria, it is shown that by treating skim milk with activated charcoal certain substances are adsorbed which render the milk unsuitable as a medium for these organisms. To reactivate the milk into a suitable medium it is necessary to add lactoflavine and also a thermostable alkaline substance which appears to be identical with pantothenic acid, the main constituent of bios. It is further shown that not only true lactic acid bacteria of milk but all other lactic acid bacteria have a definite requirement for bios and lactoflavine, while other forms, e. g. the coli and aerogenes bacteria, thrive as well in charcoal-treated milk as in the untreated.

Peptones used in bacterial media contain sufficient lactoflavine for lactic acid bacteria but are too low in bios for a normal development of lactic acid rods, although generally sufficient for the streptococci. The proteolytic enzymes in addition to supplying lactoflavine and bios apparently contain other activators favorably influencing the lactic acid rods.

It is also shown that lactic acid bacteria have a high requirement as regards their nitrogen food, and in some cases this appears to be even more specific than in the case of higher animals. Even the streptococci which grow with ammonium salts as their only source of nitrogen respond favorably to additions of histidine, leucine, creatine, and nucleic acid.

A pigment-producing organism (*Pseudomonas* sp.) isolated from discoloured butter, E. R. HISCOX (*Jour. Dairy Res. [London]*, 7 (1936), No. 3, pp. 238-243).—This report describes an organism isolated from discolored areas in butter which was capable of reproducing the color in artificial cultures. A brown color produced by the organism diffused through the medium, while a blue-black insoluble pigment, produced only at low temperatures, was concentrated in and around the bacterial cells. Other cultural characteristics are described. The organism is regarded as a species of *Pseudomonas*, but its identity is not fully established and no specific name is assigned.

Milk production and control, W. C. HARVEY and H. HILL (*London: H. K. Lewis & Co., 1936*, pp. VIII+555, pls. 2, figs. 180).—A treatise on the problem of the fluid milk supply in England. Successive chapters deal with composition and food value of milk, milk and disease, the cow, the cow shed, the dairy,

clean milk production, distribution, designated milks, the treatment of milk by heat, laboratory and other control, legislation, and the future of the milk industry.

The effect of ingested cottonseed meal upon the distribution of the constituent fatty acids of goat milk, R. W. RIEMENSCHNEIDER and N. R. ELLIS (*Jour. Biol. Chem.*, 114 (1936), No. 2, pp. 441-447).—It is reported from the U. S. D. A. Bureau of Animal Industry that after cottonseed meal feeding the butterfat constants of goat milk fat indicate a decrease in butyric and unsaturated acids and an increase in acids concerned in the Polenske values.

A study of the fatty acid distribution by the methyl ester distillation method substantiated the general information obtained from the butterfat constants, and indicated, specifically, an increase in capric, lauric, myristic, and stearic acids at the expense chiefly of palmitic and oleic acids as a result of the inclusion of cottonseed meal in the ration. No evidence of the presence of linoleic acid was observed, although acids of the arachidonic type were found.

Vitamin C in pasteurized milk, P. F. SHARP (*Science*, 84 (1936), No. 2186, pp. 461, 462).—This report from the [New York] Cornell Experiment Station discusses various factors affecting the vitamin C content of milk. Pasteurization at 63° C. for 30 min. only slightly weakened the enzyme causing oxidation of ascorbic acid, whereas heating to 77° even momentarily almost wholly destroys it. It is shown that milk which does not come in contact with copper or copper-bearing alloys at any stage of the handling process may be pasteurized by the holder method and still maintain essentially the same ascorbic acid content as raw milk of the same age, and flash pasteurization at 77° results in greater ascorbic acid potency than raw milk of the same age. The presence of 0.13 p. p. m. of copper in milk caused a marked decrease of ascorbic acid content under the former method of pasteurization, but has little effect when milk is pasteurized at the higher temperature.

New developments in the field of vitamin D milk, W. E. KRAUSS and R. M. BETHEKE (*Ohio Sta. Bimo. Bul.* 184 (1937), pp. 3-12).—This article discusses the various methods available for increasing the vitamin D content of milk, with an indication of the additional cost involved per unit of milk fortified and the vitamin D content practically attainable by the different methods. The problems involved in adequate control of fortified milks, the clinical evidence of the value of vitamin D enrichment, the possibility of fortification of other dairy products, and the future outlook for vitamin D milk are each treated briefly.

Testing cream and milk for butterfat, J. D. FOSTER (*Kentucky Sta. Regulat. Ser. Bul.* 9 (1936), pp. 28, figs. 3).—This presents a detailed description of the standard methods for conducting the Babcock test in testing cream and milk for butterfat and sets forth the provisions of the Kentucky Creamery and Testers License Law.

Discoloration and corrosion in canned cream, C. J. JACKSON, G. R. HOWAT, and T. P. HOAR (*Jour. Dairy Res. [London]*, 7 (1936), No. 3, pp. 284-290, pl. 1).—From a study of certain defects observed in samples of canned cream after several months' storage it is shown that the most common defect, designated as "purpling" of the can, is produced by excessive time and temperature of sterilization due to the liberation of active sulfur compounds which attack the tin. The addition of sodium bicarbonate as a stabilizer up to 5 g per gallon of cream exerts a slight beneficial effect.

A more serious defect observed was pitting of the can, associated with the formation of black patches causing discolored cream and black specks in the body of the cream. These black patches consist of ferrous sulfide, stannous

oxide, or both, and under experimental conditions they were observed only in cans in which the steel was deliberately exposed.

Factors influencing the loss of butterfat in churning. J. LYONS and M. O'SHEA (*Roy. Dublin Soc. Econ. Proc.*, 3 (1936), No. 1, pp. 1-18, figs. 4).—A high proportion of small fat globules in the cream, employing relatively high churning temperatures, churning cream very high or very low in butterfat content, underloading the churn, and the use of small diameter churns, all contribute to loss of butterfat during the churning process. The lower the temperature to which cream is chilled after pasteurization the lower the churning temperature, and the more completely the churn is loaded (up to rated capacity) the less is the loss in butterfat during churning but the greater is the time required for churning.

A study of the body and texture of butter. S. T. COULTER and W. B. COMBS (*Minnesota Sta. Tech. Bul.* 115 (1936), pp. 39, figs. 13).—This bulletin presents the results of a long-time study dealing particularly with that type of butter commonly graded as crumbly by Federal butter graders. The methods employed in the taking of trier samples and the apparatus employed in determining hardness, resistance to slicing, standing-up properties, and spreading qualities of butter are described. This defect, most commonly observed in winter butter, was found to be associated with, although not directly dependent upon, the composition of the butterfat. It is more correctly described by the terms "sticky" or "sticky-crumbly." In taking samples for judging a low temperature of both the trier and the butter tends to emphasize this defect, and the condition becomes increasingly less apparent as the temperature of either the trier or the butter, or both, is raised. The rapid cooling of cream, cooling to a very low temperature, churning at a low temperature, and the use of relatively warm wash water are concluded to be the main factors causing increased hardness of butter. The general quality of winter butter may be improved by avoiding excessive cooling of cream, churning at a temperature not lower than necessary to secure exhaustive churning, and washing the butter with water at from 40° to 50° F.

The influence of physical and mechanical treatment on the firmness of butter. J. LYONS (*Roy. Dublin Soc. Econ. Proc.*, 2 (1935), No. 34, pp. 541-558, figs. 2).—The temperature at which cream is pasteurized by the flash method has little or no influence on the firmness of butter, but immediate cooling after pasteurization and holding at low temperatures for from 2 to 3 hr. markedly increases the firmness of butter over that from cream which is not so cooled, and the lower the holding temperature the firmer is the butter. Increasing the holding time to 16 hr. or more is no more effective than from 2 to 3 hr. When cream has been properly cooled and held at low temperature, variation in the churning temperature (within limits) does not affect the firmness of the butter to any marked extent. Low temperature wash water adds slightly to firmness, but either underworking or overworking results in a degree of firmness below the maximum attainable by working to the correct point. Storing butter at 16° F. over long periods does not improve its firmness.

The influence of chemical composition of butterfat on the firmness of butter. J. LYONS (*Roy. Dublin Soc. Econ. Proc.*, 3 (1936), No. 2, pp. 19-33, figs. 5).—Tests conducted in the course of this study show that New Zealand and Australian butters are much firmer than either Danish or Irish butters. Other determinations included the moisture content, melting point, and Reichert-Meissl, Polenske, saponification, and iodine numbers for butter samples from each of the above sources. The relatively low unsaturated fatty acid content and the high stearic acid content are believed to be the main causes of the

exceptional firmness of the New Zealand and Australian samples. From determinations of seasonal variation in the composition of Irish butter it is concluded that the great decrease in firmness of this butter at the beginning of the season and the increase with advance of season cannot be fully attributed to variations in chemical composition.

Changes in the acetylmethylcarbinol plus diacetyl content of butter, W. L. SLATTER (*Natl. Butter and Cheese Jour.*, 27 (1936), Nos. 20, pp. 20-21; 21, pp. 18, 20, 22, 24-26).—This report from the Iowa State College indicates that acetylmethylcarbinol plus diacetyl is commonly produced in unsalted butter made with butter culture, but ordinarily is not produced in salted butter similarly made even though very little salt is added. The production of this substance was greater when 10, 15, or 20 percent butter culture was added than when 5 percent was used, and the addition of citric acid fermenting bacteria to the cream along with the butter culture increased its production in some cases, though not invariably. Higher storage temperatures and low pH in the butter favored its development. Unsalted butter regularly decreased in pH at higher holding temperatures, and the acetylmethylcarbinol plus diacetyl content declined following the point of maximum production, whereas salted butter maintained a relatively constant pH at various storage temperatures and showed little decrease in the content of this product.

Vitamin A activity of butter fat, T. S. SUTTON and W. E. KRAUSS (*Guernsey Breeders' Jour.*, 50 (1936), No. 10, pp. 906, 907, 924).—The Ohio Experiment Station has made a comparative study of the vitamin A activity and carotene content of the butterfat from Ayrshire, Guernsey, Holstein, and Jersey cows. Butterfat produced under winter feeding of alfalfa hay, silage, and grain was biologically assayed for vitamin A potency, using both curative and preventive methods with rats. Carotene determinations are reported both for winter-produced butterfat as above and for summer-produced samples when the animals had access to pasture. In all assays of vitamin A potency Guernsey and Holstein butterfats proved very similar in effect and somewhat superior to Jersey and Ayrshire butterfats, the latter two showing no significant differences in effect.

In an 8-week curative trial at relatively high fat intake and in an 8-week preventive trial all fats gave similar results, and only in the case of a 5-week curative trial at a relatively low fat intake did Holstein and Guernsey butterfat show marked superiority over Jersey and Ayrshire samples. On the basis of carotene content of butterfat under both winter and summer conditions, the breeds ranked as follows: Guernsey, Jersey, Holstein, and Ayrshire. Lack of correlation between carotene content and vitamin A activity is apparently due to inherent breed characteristics which regulate the degree of transformation of the food source of vitamin A (carotene) into the colorless form of vitamin A during the process of milk fat formation.

Tests of woods for butter containers with reference to imparting odor and flavor, E. M. DAVIS and G. C. MORBECK (*U.-S. Dept. Agr., Misc. Pub. 250* (1936), pp. 4, figs. 2).—In a study conducted at the Forest Products Laboratory, Madison, Wis., 14 species of native woods were tested under normal butter storage conditions over a 14-day period. Each species was tested when containing 6, 12, and 20 percent of moisture, both plain and paraffined. Butter samples were scored after 2, 7, and 14 days' storage. The various species in order of freedom from imparting odor and flavor to butter were white ash, white fir, soft maple, hackberry, sycamore, aspen, beech, yellow poplar, elm, black gum, basswood, cottonwood, red gum, and magnolia. The tendency of wood to impart odor and flavor to butter increased with increased storage time, and also

with increased moisture content of the wood. No species of wood having as much as 20 percent of moisture can be recommended for butter containers. The use of paraffin retarded but did not prevent the development of woody odors and flavors.

Bacterial flora in skimmilk powders, W. V. HALVERSON and F. MLEYNEK (*Northwest Sci.*, 10 (1936), No. 4, pp. 5, 6).—This brief report from the Idaho Experiment Station gives the results of the examination of 30 samples of skim milk powder, including 13 spray process, 8 vacuum process, and 9 roller process lots, for bacterial flora. Molds were found in practically all samples, the numbers ranging from 0 to 30 per cubic centimeter of 10-percent solution. Yeasts were found in only two of the samples. Total bacterial count on standard nutrient agar ranged from 3,000 to 401,000 per cubic centimeter. Acid formers were present in all but two cases, while peptonizing bacteria and *Escherichia coli* were isolated in a few instances. The most recently prepared samples were generally higher in bacterial content.

Observations on the ripening of cheeses made from raw and pasteurized milk, I. R. SHERWOOD (*Jour. Dairy Res.* [London], 7 (1936), No. 3, pp. 271-283, figs. 5).—Continuing the study of factors affecting the ripening of cheese (E. S. R., 76, p. 96), the proteolytic action of rennet, pepsin, and trypsin on milk pasteurized at various temperatures has been investigated. It is shown that within a pasteurization range of from 140° to 160° F., and particularly between 150° to 160°, certain changes occur in the milk leading to increased proteolytic action of these enzymes. Further tests indicate that this condition is not due to alteration of the protein itself but is probably due to some change in the nonprotein constituents of milk. Applying these results to cheese-ripening studies, the difference in nitrogen partition as observed between cheeses made from raw milk and from pasteurized milk and ripened in the absence of bacteria can be largely accounted for on the basis of chemical alteration produced in the milk constituents by heat treatment.

The manufacture of blue cheese (roquefort type) from homogenized cows' milk, C. B. LANE and B. W. HAMMER (*Iowa State Col. Jour. Sci.*, 10 (1936), No. 4, pp. 391-393).—This paper presents preliminary results of trials in manufacturing roquefort-type cheese from homogenized cows' milk, both in small laboratory lots and on a commercial scale. By employing certain modifications in the manufacturing process as described a satisfactory cheese is produced which ripens in a short time and regularly has a white color and a desirable soft, flaky body.

Significance of laboratory tests in the control of ice cream, F. J. BABEL (*Ice Cream Trade Jour.*, 32 (1936), No. 9, pp. 35-37).—In the microbiological analysis of ice creams, a comparison of media for determining the total bacterial count showed for tryptone-glucose-skim milk agar average counts approximately 2.5 times greater than those obtained by the standard method and also larger colonies. The average count and size of colonies obtained on standard agar plus 1 percent sucrose slightly exceeded those obtained by the standard method. Violet red bile agar proved superior to either sodium desoxycholate agar, formate ricinoleate broth, or brilliant green lactose peptone bile in the detection of the *Escherichia-Aerobacter* group. A direct relationship was noted between the total bacterial count and the yeast and mold content of ice cream.

Sodium alginate as a stabilizer for ice cream, M. J. MACK (*Ice Cream Rev.*, 20 (1936), No. 4, pp. 60, 62, 64; also in *Ice Cream Trade Jour.*, 32 (1936), No. 11, pp. 33, 34).—The Massachusetts Experiment Station presents experimental evidence that sodium alginate is a satisfactory cream stabilizer. The desired viscosity of the mix is attained without aging, thus permitting prompt freezing.

The mixes whipped readily to the desired overrun, and the finished ice cream possessed smooth texture and desirable melting characteristics. Methods for incorporating this product into the mix are outlined.

VETERINARY MEDICINE

[Report of work in animal pathology by the Florida Station] (*Florida Sta. Rpt. 1936, pp. 53, 56, 57*).—Investigations of hemorrhagic septicemia in cattle and swine, by D. A. Sanders; the effect of feeding colon organisms and dried whey on the bacterial flora of baby chicks affected with pullorum disease and the etiology of fowl paralysis, leukemia, and allied conditions in animals, both by M. W. Emmel; and plants poisonous to livestock in Florida, particularly *Crotalaria* (E. S. R., 75, p. 842), by Sanders, Emmel, and E. West, are referred to in this report of the work of the year (E. S. R., 75, p. 690).

The gizzard-worm and its transmission to chickens in Hawaii, J. E. ALICATA (*Hawaii Sta. Circ. 11 (1937), pp. 7, figs. 4*).—Although invertebrate carriers of the gizzard worm of the chicken (*Cheilosporira hamulosa*) were previously unknown in Hawaii, recent investigations by the author have shown the flour beetle *Tenebrio:des nana* and the sand hopper *Orchestia platensis*, collected from poultry farms, to be naturally infested with infective larvae of this parasite.

In experimental work 2 of 8 laboratory-raised chickens that were fed upon 2,300 grasshoppers collected in an endemic area became infested with the parasite. Three species of grasshoppers (*Conocephalus saltator*, *Atractomorpha ambigua*, and *Oxya chinensis*), a species of sand hopper (*Orchestia platensis*), and 10 species of beetles (flour beetles—*Tribolium castaneum*, *Tenebroides nana*, and *Carpophilus dimidiatus*; beetles found around poultry manure—*Dactylosternum abdominale*, *Palorus ratzeburgi*, *Typhaea stercorea*, *Litargus balteatus*, and *Euxestus* sp.; and weevils—*Oxydema fusiforme* and the rice weevil) have been experimentally determined to serve as intermediate hosts.

The findings suggest that frequent removal of chicken manure from the poultry yards and prevention of fowls from eating beetles, grasshoppers, and sand hoppers are the basis of control measures for the gizzard worm.

Coccidiosis in chickens and other birds, A. J. DURANT (*Missouri Sta. Bul. 372 (1936), pp. 12, figs. 4*).—A practical summary of information on methods applicable in combating coccidiosis in poultry and other fowl.

The immunizing value of commercial hemorrhagic septicemia aggressins, L. VAN ES and J. F. OLNEY (*Nebraska Sta. Res. Bul. 87 (1936), pp. 16*).—In the course of tests to determine their immunizing value, 13 samples prepared by 7 different concerns were examined, rabbits as well as fowls being used as test animals. The aggressin doses were administered subcutaneously and each series of test animals was divided into 3 groups, the groups receiving the injections 1 week apart. The virus, consisting of 24-hour-old bouillon cultures of *Bacillus bipolaris*, was injected intravenously to all test animals 1 week after the last group had been treated with the aggressin. This arrangement was adopted in order to determine any possible influence exercised by the length of time between the aggressin treatment and the exposure to the virus.

"The injection of hemorrhagic septicemia aggressin failed to induce an adequate protection against a subsequent inoculation with *B. bipolaris*. The average mortality rate of the treated rabbits was higher than that of the corresponding virus controls. Animals inoculated with the virus 3 weeks after the aggressin treatment showed on the average a higher death rate than the virus controls, whereas that of the groups similarly inoculated 1 and 2 weeks after receiving aggressin treatment approached the mortality rate of the control

rabbits. No substantial advantage was gained by treating the test animals with aggressin more than once. The only influence of aggressin treatment consisted of an apparent tendency to prolong the survival periods of the animals dying within 120 hr. and of a greater number surviving beyond that space of time as compared with corresponding virus controls.

"Aggressin-treated rabbits which survived the inoculation with a *B. bipolaris* of greatly reduced virulence showed a conspicuously higher mortality rate than the original corresponding virus controls when 3 weeks later the entire group was again injected with a larger dose of the same virus.

"The treatment of fowls with hemorrhagic septicemia aggressin failed to induce an adequate protection against a subsequent inoculation with the fowl cholera bacillus. In fowls treated with aggressin a marked influence on mortality or survival periods by the length of time elapsing between the aggressin treatment and the administration of the virus could not be observed. The injection of more than one dose of aggressin into fowls failed to bring about a degree of protection different from that of the birds treated only once. An adequate degree of immunity was not induced in aggressin-treated fowls exposed to fowl cholera by swabbing their palatine clefts with virulent material. In one group of fowls exposed to fowl cholera in the manner indicated the aggressin-treated birds showed a markedly lower mortality rate than the virus control birds, although their degree of protection cannot be regarded as adequate. Of the aggressin-treated fowls which were exposed to fowl cholera infection from 22 to 29 days and had survived, 50 percent were shown to still harbor the virus; whereas, of the corresponding virus control birds, only 23.8 percent were shown to harbor the infection.

"There is no reason to believe that the hemorrhagic septicemia aggressins of commerce can be depended on as a means of protection of livestock actually exposed to *B. bipolaris* infection."

The comparative study of nine presumptive test media, M. A. FARRELL (*Jour. Amer. Water Works Assoc.*, 28 (1936), No. 5, pp. 611-622; abs. in *Pennsylvania Sta. Bul.* 356 (1936), p. 31).—This is a more detailed account of comparisons between the newly suggested test media of the coli-aerogenes group of bacteria in water made by the station than that previously noted (E. S. R., 74, p. 847). See also a later note (E. S. R., 75, p. 688).

[Work with livestock diseases and parasites by the South Dakota Station] (*South Dakota Sta. Rpt.* 1936, pp. 13, 15-19, 33, 34, 37, 46).—The work of the year (E. S. R., 75, p. 691) is referred to as follows: The properties of oil of chenopodium, by J. W. Wilson and T. J. Le Blanc; alkali disease or selenium poisoning, by A. L. Moxon and W. E. Poley; and hemorrhagic septicemia, by C. C. Lipp.

A comparison of the minimum fatal doses of selenium, tellurium, arsenic, and vanadium, K. W. FRANK and A. L. MOXON (*Jour. Pharmacol. and Expt. Ther.*, 58 (1936), No. 4, pp. 454-459).—A study was made by the South Dakota Experiment Station of the relative toxicity of elements in addition to selenium that occur in the selenium areas known to produce toxic vegetation. "Rats were given intraperitoneal injections of Na_2SeO_3 , Na_2SeO_4 , Na_2TeO_3 , Na_2TeO_4 , Na_2HAsO_3 , Na_2HAsO_4 , NaVO_3 , and $(\text{NH}_4)_2\text{MoO}_4$. The minimum fatal doses were taken as the smallest doses which would kill 75 percent or more of the animals in less than 2 days. The minimum fatal doses as found are as follows: (1) Se as Na_2SeO_3 , 3.25-3.5 mg Se per kilogram; (2) Se as Na_2SeO_4 , 5.25-5.75 mg Se per kilogram; (3) Te as Na_2TeO_3 , 2.25-2.5 mg Te per kilogram; (4) Te as Na_2TeO_4 , 20-30 mg Te per kilogram; (5) As as Na_2HAsO_3 , 4.25-4.75 mg As per kilogram; (6) As as Na_2HAsO_4 , 14-18 mg As per kilogram; (7) V as

NAVO₂, 4-5 mg V per kilogram; [and] (8) Mo as (NH₄)₂MoO₄, above 160 mg Mo per kilogram. No deaths were caused by injecting Mo in doses up to 160 mg per kilogram."

Locoine, the poisonous principle of loco weed (*Astragalus earlei*), G. S. FRAPS and E. C. CARLYLE (*Texas Sta. Bul. 537 (1936), pp. 18, figs. 2*).—An account is given of the isolation of the toxic principle of *A. earlei* in comparatively pure form, to which the name "locoine" is given. It has been found to be precipitated by phosphotungstic acid and to be recovered from the precipitate by treatment with barium hydroxide. "The base can be acetylated by acetic anhydride and the toxic principle recovered by extracting the water-insoluble material with chloroform, evaporating off the chloroform, and saponifying with sodium hydroxide. The base forms salts with acids. The tartrate, citrate, chloride, and oxalate have been prepared. The tartrate and citrate were toxic to cats; the oxalate was not tested. When precipitated by alcohol, the citrate and tartrate were not crystalline. They could be crystallized by dissolving in a little water and adding about four volumes of acetone. Small microscopic rhomboidal crystals were formed. Locoine is not precipitated by silver or mercury salts. The results of tests with a large number of alkaloidal reagents are described.

"The locoine was tested for selenium and none was found."

[Work in animal pathology by the Utah Station] (*Utah Sta. Bul. 276 (1936), pp. 7-10, 71, figs. 2*).—The work of the biennium 1935-36 (E. S. R., 72, p. 382) not previously noted includes the finding that immunity from Bang's disease through natural exposure may be transitory, by D. E. Madsen; that iritis is not transmitted by F₁ progeny of breeding hens, by Madsen and B. Alder; and that inconclusive results were obtained as to the relationships of soft-curd milk to subclinical mastitis, by R. L. Hill.

[Report of work in animal pathology by the Wyoming Station] (*Wyoming Sta. Rpt. 1936, pp. 12, 13, 14, 15*).—The work of the year referred to (E. S. R., 75, p. 103) includes a study of the presence of selenium in the soil and various plants, of poisonous constituents in the ground lichen (*Parmelia molliuscula*) and *Zygadenus gramineus*, the diagnosis of blackhead of turkeys, stiff lambs, roup in chickens, and cooperative work in the eradication of Bang's disease.

The curative treatment of surra in bovines, S. K. SEN (*Indian Jour. Vet. Sci. and Anim. Husband., 6 (1936), No. 3, pp. 215-233, pl. 1, figs. 3*).—In experimental work with bovine surra the administration of Naganol proved successful in seven of nine cases treated. It is considered desirable to repeat the dose once, and, if possible, even twice, at intervals of 1 mo., particularly when the animal is intended for export to countries known to be free from this disease.

Report of the veterinary division, 1935, H. V. M. MEYER (*Trinidad and Tobago Dept. Agr. Rpt., 1935, pp. 44-46*).—The occurrence of and work of the year with livestock diseases are reported upon.

Ridding pasture of *Taenia saginata* ova by grazing cattle or sheep, W. J. and H. B. PENFOLD and M. PHILLIPS (*Jour. Helminthol., 14 (1936), No. 3, pp. 135-140*).—Experiments conducted in which a sheep and 2 calves were drenched with 3 doses each of 100,000 eggs of *T. saginata* led the authors to conclude that in all probability sheep will not acquire *Gyosticercus bovis*. It appears that by grazing sheep or cattle under certain conditions pasture contaminated with *T. saginata* ova can be freed from this parasite. In a pasture cleaning experiment the degree of accessible contamination of the experimental pasture at various times of testing was reduced from 849 to 2, representing a reduction of effective accessible eggs to 0.6 percent of the original number.

Histologic features of the intradermic reaction to tuberculin in cattle, W. H. FELDMAN and C. P. FITCH (*Arch. Path.*, 22 (1936), No. 4, pp. 495-509, figs. 10).—This contribution from the Mayo Foundation and the Minnesota Experiment Station cooperating reports upon a histological study of the later phases of the intradermic reaction to tuberculin in cattle, in which experimental and clinical material was used. "In 70 cases tissue was excised from the reactive areas of the caudal fold, and sections were prepared for histologic study. It was found (1) that the reaction to tuberculin is a rather definitely cellular reaction, predominantly histiocytic, and that it shows a predilection for the perivascular and perineural areas of the derma; (2) that while the local reactive process is confined in most instances to the papillary and reticular zones of the derma it may, if the inflammatory response is severe, extend into the tissues of the subcutis; (3) that there is no correlation between the intensity of the histologic alterations and the results of the tuberculin test as observed clinically; (4) that there are no distinguishing criteria in the histologic picture to indicate whether demonstrable lesions of tuberculosis are present in a given animal; and (5) that in all cattle in which these characteristic changes occur the uniformity of the reaction suggests the possibility of the existence of a common or closely related sensitizing agent."

Observations on Yellowstone elk, H. B. MILLS (*Jour. Mammal.*, 17 (1936), No. 3, pp. 250-253).—The results of a study of the parasites, diseases, etc., of elk made during the course of the reduction of the Yellowstone herd undertaken early in 1935 are reported upon. Of the 11 diseases and parasites observed, the transmission of 9 is greatly aided by overcrowding and by feeding on overgrazed range.

Studies of physical properties and agglutinability of Br. abortus plate antigens from several sources, C. P. FITCH and C. M. THOMPSON (*Cornell Vet.*, 26 (1936), No. 3, pp. 222-230).—Studies of plate antigens for the diagnosis of Bang's disease, conducted at the Minnesota Experiment Station over a number of years, have shown that there is a wide variety of products prepared in various ways. The results of tests of 13 antigens obtained from various sources, including official laboratories and commercial antigens purchased on the open market, are here reported upon, the details being given in seven tables. "Since these data were collected we have studied additional plate antigens from other sources and have found just as wide a variation. This study indicates the need of some method for the preparation of plate antigen which will insure a more uniform product for the diagnosis of Bang's disease. Some years ago nearly as wide a variation occurred with test tube antigen, but this has been corrected. . . . Some States are employing the plate test. It is also being used quite extensively in making diagnoses for interstate shipments in the private practice of many veterinarians, and for official work in some commonwealths. We firmly believe that the results of this study show clearly the necessity of using more uniform plate antigens than are now being employed for the diagnosis of Bang's disease."

The differential diagnosis of equine abortion, with special reference to a hitherto undescribed form of epizootic abortion of mares, W. W. DRMOCK and P. R. EDWARDS (*Cornell Vet.*, 26 (1936), No. 3, pp. 231-240).—Following a brief history of the occurrence of and work with abortion in mares in the United States, the authors report upon further work by the Kentucky Experiment Station (*El. S. R.*, 69, p. 433). The finding that the abortions met with in mares immunized against *Salmonella abortivo-equina* are due to a filtrable virus is reported. On the basis of present knowledge abortion among mares is grouped under four headings: (1) *Salmonella* abortion, (2) streptococci

abortion, (3) virus or epizootic abortion, and (4) abortion due to miscellaneous causes. Transmission experiments with virus abortion in which mice, rabbits, guinea pigs, and mares were used are reported upon. In a number of outbreaks a convalescent serum obtained 30 days following abortion was injected intravenously or subcutaneously. Administered as a preventive for virus abortion, it has not protected mares already infected. It was observed in the field that no abortions occur after from 14 to 21 days following injection of the serum.

For the prevention and control of abortion in brood mares it is recommended that (1) all the pregnant mares be vaccinated against *Salmonella* abortion each year, 2 or 3 mo. following the close of the breeding season; (2) only healthy mares be mated to healthy stallions and kept under scrupulous cleanliness to prevent streptococcal abortion; (3) the brood mares be kept in small groups so as to minimize the possibility of the spread of epizootic abortion and other infectious diseases; and (4) that the brood mares be kept healthy, reasonably free of parasites of the digestive tract, and fed a ration of hay and grain that contains all the essential elements of nutrition.

The incidence and types of streptococci in first-calf heifers at parturition, W. T. MILLER (*Cornell Vet.*, 26 (1936), No. 3, pp. 241-248).—In the studies reported samples of colostrum were collected immediately after parturition from each quarter of the udders of 100 first-calf heifers from a herd containing cows affected with chronic streptococcal mastitis.

"Streptococci were found in the first samples from one or more quarters of 27 animals. Second samples were not obtained from 7 of these cases. In the remaining 20 cows, streptococci were not present in 12 at the second examination. Altogether, 38 strains of streptococci were isolated. These strains fell into 20 different groups according to their behavior in differential media. Many of the strains resembled streptococci which can be found on the skin of the animal or in the stable and litter. *S[treptococcus] agalactiae* was found in 3 animals at the first examination."

Two cases of infection due to *Clostridium histolyticus* in the horse, E. R. FRANK and J. P. SCOTT (*Cornell Vet.*, 26 (1936), No. 3, pp. 252-257, figs. 3).—Reports are contributed from the Kansas Experiment Station on two cases of infection with *C. histolyticus* recently treated.

How mastitis has been controlled in New York State dairy herds, D. H. UDALL (*Cornell Vet.*, 26 (1936), No. 4, pp. 324-330).—A review of the results obtained in the control of mastitis in dairy herds in New York, with special reference to the methods employed.

Report of investigations of cattle poisoning around Payne Lake, Jefferson County, New York, W. M. EVANS (*Cornell Vet.*, 26 (1936), No. 4, pp. 337-341).—Investigations made of the loss of dairy cattle from poisoning due to algae or other organisms consumed in lake water are reported upon. A list is given of 10 forms of blue-green algae, protozoa, and green algae found present. The symptoms observed in the affected animals were similar to those described by Fitch in his report of "water bloom" poisoning in Minnesota (*E. S. R.*, 71, p. 241).

A case of tetany with hypomagnesemia in a dairy cow, H. J. METZGER (*Cornell Vet.*, 26 (1936), No. 4, pp. 353-356).—A case report contributed from the Kentucky Experiment Station.

Pathogenicity and virulence of certain bacteria, C. A. BRANDLY and B. GRAHAM (*Science*, 84 (1936), No. 2179, p. 315).—In continuation of earlier work by Brandly at the Kansas Experiment Station with filtrable viruses (*E. S. R.*, 74, p. 399; 75, p. 546), the authors report upon observations in Illinois of the

effect of introducing several species of bacteria into developing eggs of the chicken and other domestic fowl.

"With given strains of freshly isolated *S[almonella] pullorum* the extent and severity of the lesion produced as well as the survival time of the embryo were quite definitely and uniformly correlated with the quantity of the inoculum and the virulence of the culture for baby chicks.

"These results suggested the possible adaptability of the method of egg inoculation for determining the pathogenicity and for ascertaining the virulence of various strains and species of bacteria. In investigating this hypothesis the preliminary observations here recorded were confined to inoculations upon the chorioallantoic membrane of eggs incubated 10 to 15 days prior to treatment. The cultures used represented four strains of *Brucella abortus* var. *boris* and *suis*, three strains of diplococci of equine origin, three strains of hemophilic bacteria isolated from the upper respiratory tract of young chickens, eight species of *Salmonella*, and three species of *Pasteurella*. Eggs employed as controls were injected with the sterile suspending medium or with suspensions of the various bacteria killed by heat. Proof of infection of the embryo and/or its membranes was established by the production of gross lesions and direct pure culture isolation of the organism inoculated.

"The cultures of diplococci and hemophiles appeared virtually devoid of pathogenicity for the developing egg even in the relatively large quantities employed (as much as 0.2 cc of the undiluted 15- to 24-hr. broth cultures). These two groups of organisms in other trials were not proved to possess specific pathogenic properties for the homologous host. *Brucella*, *Pasteurella*, and *Salmonella* cultures were lethal to the embryo in very dilute concentrations, while the control suspensions of dead organisms produced no more than slight local injury to the extra-embryonic tissues and were seldom associated with the death of the embryo.

"Marked differences in virulence for developing eggs were manifested between smooth stock and freshly isolated cultures of *Salmonella* and *Pasteurella*. Simultaneous comparative titrations with *Pasteurella* cultures on 2- to 10-day-old chicks revealed a correlation in results, although much less definite and uniform than in the egg inoculation method. The *P. avicida* culture, when inoculated subcutaneously, killed chicks in dosages 10 times smaller than were required with the *P. equiseptica*, while *P. cuniculicida* required larger doses than *P. equiseptica*. For eggs the *P. equiseptica* and *P. cuniculicida* required dosages approximately 10 times greater than did *P. avicida* to kill chicken embryos within 48 hr. Intracranial inoculations of the *P. avicida* and *P. equiseptica* strains into a group of nine horses gave results which could be interpreted as validating the titrations upon eggs and chicks. However, the more uniform and accurate measurements of virulence obtained by egg inoculation as compared to animal inoculation emphasize the superiority of the new method.

"The delicacy with which differences of pathogenicity and/or of virulence among strains of certain bacteria may be determined by inoculating the developing avian egg suggests that this method may also be utilized to detect alterations in these characters among variants of a certain strain."

The relative value of methods of examination for chronic mastitis of the bovine [trans. title], G. J. HUCKER and P. A. HANSEN (*Lait*, 14 (1934), Nos. 133, pp. 226-248, pl. 1, figs. 2; 134, pp. 337-356, fig. 1).—This contribution from the New York State Experiment Station deals with the methods that have been proposed for the detection of chronic mastitis. Reports of earlier work by Hucker have been noted (E. S. R., 74, p. 258).

On the treatment of undulant fever with Fouadin, C. Z. NEUMAN (*Lancet* [London], 1936, I, No. 18, pp. 1001, 1002).—A report is made of eight cases of undulant fever due to *Brucella* which were treated by intramuscular injection of Fouadin (antimony bispyrocatechin disodium sulfonate), in the gluteal region with (in adults) 1.5 cc on the first day, 3.5 on the second day, followed by from 4.5 to 5 cc on alternate days. In the treated cases there were no waves of fever after the first, although such waves are one of the characteristics of the disease. It was found that Fouadin apparently does not influence the onset of certain complications or sequelae such as arthritis.

Undulant fever treated with Fouadin, G. M. TANFER (*Lancet* [London], 1936, II, No. 12, pp. 684, 685).—A case report on undulant fever resulting from *Brucella* infection treated with the new antimony preparation Fouadin in the manner described by Neuman, above noted, in which there was no unfavorable reaction and the temperature began to subside after the second dose, complete recovery taking place in 8 weeks.

Annual report of the veterinary department for the year ended 31st December 1935, R. L. L. HART ET AL. (*Uganda Vet. Dept. Ann. Rpt., 1935, pp. 20*).—Included in this report (E. S. R., 74, p. 540) are accounts of the occurrence of and control work with infectious diseases of livestock and with *Glossina morsitans*.

The development of Theileria dispar in the bovine and in the tick Hyalomma mauritanicum [trans. title], E. SERGENT, A. DONATLEN, L. PARROT, and F. LESTOQUARD (*Ann. Inst. Pasteur*, 57 (1936), No. 1, pp. 30–55, pl. 1, figs. 6; also in *Arch. Inst. Pasteur Algérie*, 14 (1936), No. 3, pp. 259–294, pl. 1, figs. 10; abs. in *Rev. Appl. Ent.*, 24 (1936), Ser. B, No. 10, pp. 246, 247).—An account of the biology of the causative organism of Mediterranean coast fever, a form of bovine piroplasmiasis, and in *H. mauritanicum*, the tick vector. A list is given of 38 references to the literature.

The sylvatic plague committee, K. F. MEYER, (*Amer. Jour. Pub. Health*, 26 (1936), No. 10, pp. 961–969).—This report relates to the purpose and duties of a committee on plague among wild rodents, authorized by the western branch of the American Public Health Association in July 1935.

Two types of epizootics give rise to correspondingly different human epidemics. The form for which wild rodents serve as the great reservoir (72 species definitely known to suffer from spontaneous plague) spreads slowly from colony to colony, invariably independent of man's lines of communication, and is, as a rule, located in deserts or steppelike countries. It is epidemiologically rural plague, and so different from rat plague that the name sylvatic plague has been applied to it by R. Jorge.

Enzootic haematuria (haematuria vesicalis) of cattle in South Australia, L. B. BULL, C. G. DIKINSON, and A. T. DANN (*Austral. Council Sci. and Indus. Res. Pam.* 33 (1932), pp. 24).—An account is given of this affection as it occurs in a restricted area in South Australia.

The distribution of the gastro-intestinal parasites of sheep in Queensland, F. H. S. ROBERTS (*Queensland Agr. Jour.*, 46 (1936), No. 1, pp. 30–37, fig. 1).—In this discussion of the occurrence of intestinal parasites of sheep in Queensland, a table is given recording the frequency with which the 23 helminths considered were found in the 122 viscera specimens examined.

Vaccination of sheep: Technique adopted, R. N. WARDLE (*Jour. Dept. Agr. Victoria*, 34 (1936), No. 10, pp. 537–540, figs. 5).—A description is given of the method employed in the vaccination of sheep against black disease and of sheep or lambs against enterotoxemia (pulpy kidney).

Report of the division of entomology and pathology, A. F. BELL (*Queensland Bur. Sugar Expt. Stas. Ann. Rpt.*, 36 (1936), pp. 19-27, fig. 1).—The work of the year (E. S. R., 75, p. 808) referred to relates particularly to the gray-back cane beetle *L[epidoderma] albohirtum*, the New Guinea sugarcane weevil, armyworms, and wireworms (*Lacon variabilis*). Brief reference is made to the introduction of the giant toad *Bufo marinus* from Hawaii.

[Pullorum disease (bacillary white diarrhea) in Australia], T. G. HUNGERFORD (*Agr. Gaz. N. S. Wales*, 46 (1935), No. 8, pp. 469-471, figs. 2; 47 (1936), No. 11, pp. 648-650, fig. 1).—A brief practical account is given, in the first contribution, of this disease in New South Wales, where, because of the loss caused, some commercial poultry farmers have found it impossible to continue in business. The later account considers some of the more important features of the disease among chicks and reports upon it as a disease of adult fowl.

Control black disease in sheep by using bluestone for snail destruction (*Agr. Gaz. N. S. Wales*, 47 (1936), No. 7, p. 364).—Reference is made to the control work with black disease in sheep, due to *Clostridium oedematiens*, through the use of copper sulfate for the destruction of the intermediate snail host of the liver fluke.

Mastitis from the standpoint of a practitioner, C. H. CASE (*Jour. Amer. Vet. Med. Assoc.*, 90 (1937), No. 2, pp. 137-153, figs. 5).—A discussion of the importance and the practical application of the newer knowledge in the detection, treatment, and control of mastitis in the dairy herd.

Pyelonephritis of cattle and horses, W. L. BOYD and L. M. BISHOP (*Jour. Amer. Vet. Med. Assoc.*, 90 (1937), No. 2, pp. 154-162, figs. 2).—This practical summary of information, based upon a review of the literature and observations at the Minnesota Experiment Station, considers the etiology, symptoms, diagnosis, pathology, and treatment of pyelonephritis as found in cattle and horses.

Control of parasites in sheep, J. H. RIEZT (*Jour. Amer. Vet. Med. Assoc.*, 90 (1937), No. 2, pp. 163-170).—A practical discussion of the sheep parasite control problem, based upon work at the West Virginia Experiment Station.

The use of acidophilus milk in the treatment of dysentery of young animals, J. N. SHAW and O. H. MUTH (*Jour. Amer. Vet. Med. Assoc.*, 90 (1937), No. 2, pp. 171-175).—Contributing from the Oregon Experiment Station a brief account is given of the successful treatment of lambs, calves, colts, and pups for dysentery through the use of milk soured by *Lactobacillus acidophilus*. It is pointed out that the milk to be effective must be properly made and cared for.

Field observations on the incidence of fowl leukosis in hatching eggs and chicks, B. A. BEACH (*Jour. Amer. Vet. Med. Assoc.*, 90 (1937), No. 2, pp. 194-202).—A brief report is made of studies of fowl leucosis conducted on 14 Wisconsin farms where it had not appeared until the spring of 1935. In all cases the symptoms first appeared in chicks. In 12 instances the chicks came from three hatcheries, while in the 2 others they were hatched from eggs produced on the farm. One of the flocks was shown to be infected, while in the other flock the source of the infection was not determined.

Observations on anaplasmosis in Idaho, G. W. STILES, JR. (*Jour. Amer. Vet. Med. Assoc.*, 90 (1937), No. 2, pp. 212-214).—A report is made of the occurrence of anaplasmosis in a herd of adult grade Herefords, this being the first record of its occurrence in Idaho. It is now known to occur in 19 States of the Union.

[Contributions on Bang's disease] (*Jour. Amer. Vet. Med. Assoc.*, 90 (1937), No. 3, pp. 268-305).—The following contributions on Bang's disease were presented at the annual meeting of the United States Live Stock Sanitary Association at Chicago in December 1936 (E. S. R., 75, p. 101): Progress in the Federal-State Bang's Disease Program, by A. E. Wight (pp. 268-272); Area Work in Bang's Disease Control, by H. C. Givens and R. E. Brookbank (pp. 273-284); The Attitude of the Breeder and the Milk Producer Toward the Control of Bang's Disease, by W. S. Moscrip (pp. 287-291); and Experiences in the Control of Bang's Disease in California, by K. G. McKay (pp. 292-301). The contributions are followed by a Report of the Committee on Bang's Disease, by C. P. Fitch et al.

Experiments with crystal-violet hog cholera vaccine, T. W. MUNCE (*Jour. Amer. Vet. Med. Assoc.*, 90 (1937), No. 3, pp. 307-319).—A report is made of preliminary experimental work, the details of which are given in five tables. It is pointed out that the work reported is not sufficiently comprehensive to justify definite conclusions regarding any phase of the subject yet investigated.

Progress of hog cholera control with tissue vaccine, W. H. BOYNTON, G. M. WOODS, and F. W. WOOD (*Jour. Amer. Vet. Med. Assoc.*, 90 (1937), No. 3, pp. 321-325).—The authors have found (E. S. R., 70, p. 534; 74, p. 542) that the tissue vaccine method produces an adequate immunity, markedly reduces the possibility of losses from pneumonia or enteritis, and therefore can be satisfactorily substituted for the simultaneous method. It is pointed out that the progress obtained with this method, which does not introduce active virus into the field, suggests the brightest outlook for hog cholera control thus far.

Swine pox, C. MURRAY (*Jour. Amer. Vet. Med. Assoc.*, 90 (1937), No. 3, pp. 326-330).—A brief report of a study of a few pigs in Iowa from a herd showing a high incidence of swine pox infection.

Anthrax in swine, L. VAN ES (*Jour. Amer. Vet. Med. Assoc.*, 90 (1937), No. 3, pp. 331-340).—A summary of anthrax as met with in swine.

A discussion of factors influencing the course of coccidiosis, E. E. TRYZZER (*Jour. Amer. Vet. Med. Assoc.*, 90 (1937), No. 3, pp. 341-346).—In the course of this discussion the nature and etiology of chronic coccidiosis and some of the problems having to do with certain aspects of coccidial infection, concerning which very little is known, are taken up.

[Contributions on bovine tuberculosis eradication work] (*Jour. Amer. Vet. Med. Assoc.*, 90 (1937), No. 3, pp. 353-373).—The following contributions on bovine tuberculosis eradication were presented at the annual meeting of the United States Live Stock Sanitary Association at Chicago in December 1936 (E. S. R., 75, p. 101): Progress and Status of Cooperative Tuberculosis Eradication Work, by A. E. Wight (pp. 353-358); Reaccreditation of Range and Semi-Range Modified Accredited Tuberculosis-Free Areas, by W. J. Butler (pp. 359-363); Problems and Policies in Completing Tuberculosis Eradication, by H. R. Smith (pp. 363-369); and Report of Committee on Tuberculosis, by J. L. Axby et al.

The epidemiology and control of equine encephalomyelitis, E. RECORDS (*Jour. Amer. Vet. Med. Assoc.*, 90 (1937), No. 3, pp. 373-380).—A contribution presented at the annual meeting of the United States Live Stock Sanitary Association at Chicago in December 1936.

Experimental vesicular exanthema of swine, A. B. CRAWFORD (*Jour. Amer. Vet. Med. Assoc.*, 90 (1937), No. 3, pp. 380-395, figs. 2).—The findings in experimental studies of an exanthematous disease in hogs resembling foot-and-mouth disease, but which occurs only in California, are reported. Four strains of

virus (A, B, C, and D) from different sources in the outbreaks of 1933 and 1934 were studied. Each of these strains appeared to be a distinct type, causing an immunity to the homologous type but not to the other three. Two of the types (B and D) were infectious only for swine, while the other two types (A and C) were infectious for horses as well. Cattle, sheep, goats, guinea pigs, and hedgehogs were not found to be susceptible to any of the four types of virus. Experimentally, this disease was communicable as a result of direct infection, but relatively only slightly so as a result of indirect infection. Hogs recovered from vesicular exanthema are susceptible to vesicular stomatitis as well as foot-and-mouth disease. Studies of vesicular exanthema suggest a closer relationship to vesicular stomatitis than to foot-and-mouth disease, but definitely indicate vesicular exanthema to be a separate though closely related disease.

Paratyphoid infection of fowls, P. R. EDWARDS (*Jour. Amer. Vet. Med. Assoc.*, 90 (1937), No. 3, pp. 403-408).—This contribution from the Kentucky Experiment Station reports on some of the newer developments in the knowledge of paratyphoid infection of fowls and calls attention to the direction which study of the problem is taking. It is concluded that, since four types of *Salmonellas* are definitely known to be transmitted through the egg in several species of domestic fowls, there can be little doubt that other species may be egg-borne.

Fowl-pox vaccination of day-old and older chicks.—Second report, R. E. LUBBEHUSEN and J. R. BEACH (*Jour. Amer. Vet. Med. Assoc.*, 90 (1937), No. 3, pp. 430-446).—This further contribution (E. S. R., 75, p. 110) reports upon a comparison of the effects of vaccination of chicks at the ages of 1 and 27 days and of the weight gains and mortality of chicks vaccinated at the age of 1 day with those of nonvaccinated controls to the age of 10 weeks, the vaccination of chicks at the ages of 1, 18, and 28 days compared on the basis of weight gains and mortality with nonvaccinated controls, and the vaccination of chicks at the ages of 1, 21, and 42 days and of groups of chicks at the ages of 1, 75, 89, 108, and 117 days, the details being given in five tables.

Vaccinating day-old and older chicks, R. L. LUBBEHUSEN and J. R. BEACH (*Nulaid News*, 14 (1937), No. 11, pp. 35-37, 63).—This practical contribution is based upon the work above noted, which is summarized as follows:

"(1) Fowl pox vaccinations of day-old chicks resulted in a systemic reaction sufficient to cause a temporary inhibition of growth gains and a lowering of vitality for variable periods thereafter. During the period of lowered resistance, exposure to unfavorable environment or concurrent disease may result in excessive mortality. (2) Vaccination between the ages of 2 and 6 weeks was followed by a systemic reaction of slower onset and one that became less and less severe as the age at vaccination increased, compared with the reaction of day-old vaccinated groups. (3) Vaccination between the ages of 75 and 117 days, even though the birds were vigorous, was followed by a systemic reaction which became increasingly severe as the vaccination age increased. This systemic reaction caused a temporary inhibition of growth gains. In birds vaccinated at these ages, as in those vaccinated between the ages of 1 and 42 days, the mortality following vaccination shock is largely dependent upon the vigor of the birds and the unfavorable factors to which they may be subjected."

Fowl cholera, L. VAN ES (*Jour. Amer. Vet. Med. Assoc.*, 90 (1937), No. 3, pp. 446-450).—A practical summary of information on fowl cholera.

[Annual administration report of the Madras Civil Veterinary Department for the years 1934-35 and 1935-36], P. T. SAUNDERS ET AL. (*Madras Civil Vet. Dept., Ann. Admin. Rpts.*, 1934-35, pp. II-37+3, pl. 1; 1935-36, pp.

II+52+8).—Accounts of the occurrence of and control work with diseases and parasites of livestock are included in these annual reports (E. S. R., 73, p. 537).

Variation in animal viruses: A review, G. M. FINDLAY (*Jour. Roy. Micros. Soc.*, 56 (1936), No. 3, pp. 213-299).—In this review, which is presented with a 15-page list of references to literature, more than 30 animal viruses are considered. "The variants observed are of two types: (1) Variants associated with pathological lesions unlike those produced by the parent strains, but without any great antigenic difference; (2) variants associated with pathological lesions like those produced by the parent strains, but with considerable antigenic difference, the antigenic differences being, as a rule, quantitative rather than qualitative in character.

"Both types either occur naturally or can be produced artificially under laboratory conditions. If a variant virus exhibits a high degree of antigenic difference and at the same time produces new pathological lesions an apparently new disease entity has arisen. Virus variants may appear as a result of growth in (1) the same species and the same tissue, more commonly either in (2) the same species and a different tissue or in (3) a different species and a different tissue. When virus variants appear in the same species and the same tissue no explanation is forthcoming as to why the variants should become dominant. No essential difference is to be found between the variations of animal viruses and those occurring in unicellular and multicellular organisms. It is suggested that certain virus variants are true mutations, others are akin to *Dauermodifikationen*, though in viruses, where there seems little or no possibility of contrasted parts corresponding to nucleus and cytoplasm, the distinction between Lamarckian and genetic variation virtually breaks down. The occurrence of virus variants throws light on the nature of animal viruses, for it is difficult to explain the variations observed except by regarding viruses as organized living entities."

AGRICULTURAL ENGINEERING

[Agricultural engineering investigations by the Florida Station], B. S. CLAYTON and A. DAANE (*Florida Sta. Rpt. 1936*, pp. 125-127).—The progress results are briefly presented of a cooperative study with the U. S. D. A. Bureau of Agricultural Engineering relating to the effect of water control on peat and muck soils.

[Agricultural engineering investigations by the Pennsylvania Station] (*Pennsylvania Sta. Bul. 336* (1936), pp. 17-19).—Progress results are briefly presented of investigations on electric refrigeration on dairy farms, by R. U. Blasingame and J. E. Nicholas; stop hitches for tractors and corn and potato production with mechanical power, both by Blasingame and A. W. Clyde; artificial curing of alfalfa and other forage crops, by Clyde and C. O. Cromer; temperature distribution as a function of electric brooder performance, by Nicholas and E. W. Callenbach; and a vacuum milk cooler, by Nicholas.

[Agricultural engineering investigations by the South Dakota Station], R. L. PATTY and T. M. OLSON (*South Dakota Sta. Rpt. 1936*, pp. 5-8, 19).—Progress results are briefly presented of investigations on field machinery hitches for tractors and large horse teams (E. S. R., 75, p. 406), rammed earth for farm building walls (E. S. R., 75, p. 708), corn harvesting machinery, protective coverings and life of steel fence posts, rammed earth walls in poultry house construction, and making ice in an insulated well.

[Agricultural engineering investigations by the Utah Station] (*Utah Sta. Bul. 276* (1936), pp. 49-54, figs. 3).—Progress results are briefly presented of investigations on drainage and irrigation conditions in Millard County, snow

surveys, effect of deep cultivation on water penetration, and irrigation efficiency, especially methods of irrigation and the needs for corn.

Groundwater law in Arizona and neighboring States, G. E. P. SMITH (*Arizona Sta. Tech. Bul.* 65 (1936), pp. 48-91, figs. 5).—This bulletin discusses ground water law in Arizona and neighboring States to aid in the proper consideration of any further litigation, to stimulate widespread discussion to precede any new legislation, and to give ground water users an understanding of the nature of water rights.

Determining flood discharges from small watersheds, D. L. YARNELL (*Agr. Engin.*, 18 (1937), No. 1, pp. 18, 14, figs. 4).—In a brief contribution from the U. S. D. A. Bureau of Agricultural Engineering a graphic method of representing the direct relationship between the amount of rainfall and flood discharges is described. This makes it apparently possible to predict flood magnitudes and frequencies from fragmentary or short-period data.

Supplemental irrigation in the humid region (*Agr. Engin.*, 18 (1937), No. 1, p. 28).—This is the report of the committee on supplemental irrigation of the American Society of Agricultural Engineers. Data are presented for 33 States indicating total acres irrigated amounting to 947,292, of which 26,623 are irrigated by sprinkling systems and 841,351 by surface-flooding methods.

Terrace cross sections as influenced by soil, crops, land slopes, and farm machinery, A. T. HOLMAN (*Agr. Engin.*, 18 (1937), No. 1, pp. 5-8, fig. 1).—This contribution from the U. S. D. A. Bureau of Agricultural Engineering outlines some of the factors that seem important in terrace design and points out some of the variations of terraces in size, shape, and capacity.

It is concluded that although difference in soil type eventually may influence the design, construction, and operation of terraces, present information does not justify radical departure from conventional terrace design and specification. The rate and quantity of run-off from terraced land vary materially for different crops, but equally large variations in run-off and erosion occur for the same crop in different stages of its growth and for different seasons and climatic conditions. Present data indicate that it is an unsound practice to lower the standard of terraces on the assumption that cover crops, including legumes and small grains, and rotations and strip cropping will greatly reduce run-off and erosion from the most damaging rains.

The degree of land slope continues to be the dominant factor in determining the spacing of terraces and in limiting the width of terraces. Present data and experience indicate that conservative spacing of terraces should be continued.

Terrace construction should be accomplished in a manner that prevents the development of a furrow at the base of the terrace on the lower side. Tillage and maintenance practice should be so accomplished that a uniform slope of soil will develop from the crown of a terrace to the bottom of the channel of the next lower terrace. A net terrace height of 13 in. has conveyed flows of 6.1 sec.-ft., but the cross section and channel were large. New terraces should have a minimum height of 18 in., if the spacing, length, and grade are normal.

Good terraces have been effective in preventing from 80 to 85 percent of the erosion occurring for different crops. The conservative design of terrace cross sections requires ample channel area to prevent overtopping and adequate size and stability of the ridge to prevent breaking.

The fundamental approach to tillage and traction research problems, R. W. TRULLINGER (*Agr. Engin.*, 18 (1937), No. 1, pp. 17-19).—In a brief contribution from the U. S. D. A. Office of Experiment Stations a historical review of accomplishments in tillage and traction is presented as a background

for an exposition of some of the soil dynamics problems involved in the development of these practices and means for their solution.

Rubber for roadless tractors and trailers, A. HAY (*Rubber Growers' Assoc., Rubber and Agr. Ser. Bul. 3* (1936), pp. 13, figs. 11).—The use of rubber in the traction mechanisms of track-laying type tractors is briefly described and illustrated.

The development of a low cost hay drier, J. W. WEAVER, JR. (*Agr. Engin., 18* (1937), No. 1, pp. 25–27, 46, figs. 7).—This paper reports the progress results of investigations conducted by the Tennessee Valley Authority on combination natural field curing and artificial curing of hay. The studies have related primarily to the development of low-cost equipment for artificial drying to supplement the conventional field drying. These have included tests of various devices, including the introduction of warm or heated air under pressure into entire haymows of barns.

The barn tests showed that the kilowatt-hour consumption of electricity per dry ton varied greatly throughout, dependent largely upon initial moisture content of hay, variety of hay used, air conditions, and the need for observations requiring power beyond that necessary to complete the normal drying cycle. Further observations are necessary before any definite average figure can be given, and then it will vary with the variety of hay being dried.

Little difficulty was experienced in drying clean hay of the small stem varieties, such as alfalfa and lespedeza. The higher the grass content in the hay the more difficult it was to dry. The large stem varieties of hay, such as Mammoth Yellow soybean, proved difficult in that the drying was slow and drawn out over a long time. Present indications are that drying is as rapid with intermittent blowing as with continuous blowing, but further observations are needed to find the extent to which this is true. Indications with this plan of drying are that a barn with a haymow of from 20- to 40-ton capacity can be equipped for drying the season's hay crop with an investment of about \$300.

Most of the tests conducted to date dealt with hay of above the average grass and weed content. Weather conditions were at times adverse, though a period of 3 or 4 days of rain and high humidity is yet to be encountered during the critical drying period of from 8 to 10 tons of hay. Further observations are believed necessary before this system can be declared entirely successful.

Distribution and costs of steam, electrical power, and labor in representative Idaho creameries, J. B. RODGERS, D. R. THEOPHILUS, H. BERESFORD, and J. L. BARNHART (*Idaho Sta. Res. Bul. 12* (1936), pp. 35, figs. 8).—The results of a cooperative investigation are presented on the basis of equipment and costs per unit of each product processed. The study was conducted during the months of June, July, and August, one full month being spent in each creamery.

The boiler capacity at two creameries was 620 and 675 boiler horsepower, and the boiler efficiency averaged 74.8 percent. The cost of generating steam averaged 33 ct. per 1,000 lb. of steam where an average of 294,659 lb. was generated per day. The average steam consumption of the driers was 1.42 lb. per pound of milk evaporated. Steam consumption of the straightaway can washer was 2.9 lb. per can as compared with 2.2, 1.62, and 1.42 for the rotary washers.

The boiler horsepower required for the operation of the 720-can capacity straightaway can washer was 36.8 as compared with 11.96, 14.79, and 16.10 for the 360-can capacity rotary can washers. The average quantity of steam required to pasteurize 100 lb. of cream was 8.84 lb. The driers used 65 and 80 percent of the total steam generated at two creameries. The direct method of preheating milk for the driers required less steam than indirect heating and

decreased the capacity of driers, as the milk was diluted by the amount of steam condensed. Average steam used per 1,000 lb. of milk and cream received was 1,792.5 lb., or a cost of 59.1 ct.

Electrical power peaks can be eliminated by staggering power operations. A synchronous motor correctly operated will raise the plant power factor and lower power costs. A maximum demand limiting device aids in lowering power costs. Some pasteurizing vats were found to be overmotored. Churn motors operate under various degrees of load during a churning cycle, ranging from negative loads to overloads. Churns operated at rated capacity require less power per 100 lb. of butter churned than when operated below rated capacity. The long-barrel, small-diameter churn used less power per 100 lb. of butter than the short-barrel, large-diameter type of churn. The electrical energy required to churn fresh cream was 23.1 percent greater than was required to churn aged cream. Only one-half as much power was required to drive the drier rolls for buttermilk as was required for skim milk. The straightaway can washer used 1.83 kw.-hr. per 100 cans as compared with 0.93, 1.31, and 0.91 kw.-hr. for the rotary washers. The average energy consumption per 1,000 lb. of milk and cream received was 10.38 kw.-hr. when the average daily quantity received was 174,900 lb. The average energy cost per kilowatt-hour was 1.46 ct. when an average of 51,477 kw.-hr. per month was used.

Steam, electricity, and labor averaged 28.35, 13.45, and 58.20 percent, respectively, of the total energy cost of manufacturing butter and 78.55, 9.15, and 12.30 percent, respectively, of the total energy cost of manufacturing milk powder. Labor represented 70.9 and 68.84 percent, respectively, of the total energy cost of manufacturing ice cream and popsicles. The cost of electrical energy for manufacturing ice cream and popsicles averaged 29.95 percent of the total cost. The average total cost of steam, electricity, and labor used in manufacturing butter was 55.95 ct. per 100 lb. of butter, in manufacturing milk powder \$1.52 ct. per 100 lb. of powder, manufacturing 1 gal. of ice cream 12.72 ct., and in manufacturing 1 doz. popsicles 3.218 ct.

Poultry house construction, F. C. ELFORD and H. S. GUTTERIDGE (*Canada Dept. Agr. Pub. 506 (1936), pp. 47, figs. 45*).—This is a revision of a bulletin previously noted (E. S. R., 64, p. 81).

Tests of chick brooders, E. T. SWINK (*Virginia Sta. Bul. 306 (1936), pp. 16, figs. 9*).—This bulletin reports the results of a series of tests on several types of brooders. The object was to determine (1) the fuel consumption of each type of brooder as a basis of comparing operating costs, (2) the comparative brooding results obtained, and (3) the most practical type of electric brooder for use on Virginia farms.

Six brooder houses approximately 9 by 12 ft. in dimensions were used. They were not insulated, had single thickness tongue and grooved floors, and their design was similar to the standard V. P. I. portable colony houses. The same principle of ventilation was used in all houses, and a uniform exposure was obtained.

The following brooders were selected: (1) Standard 56-in. electric with natural ventilation, (2) standard 56-in. electric with forced ventilation unit, (3) home-made electric using a 52-in. metal hover from a discarded fuel-type brooder, (4) home-made electric 72 by 30 by 9.5 in. constructed of wood, (5) commercial coal brooder, (6) commercial kerosene brooder, and (7) commercial wood stove. All electric brooders used in the test had "black heat" or low temperature heating elements.

The results of the tests show that probably too much stress has been placed on maintaining as uniform brooding temperatures as possible under the hover or canopy. Good brooding results may be had from electric, kerosene, coal, or wood brooders when properly operated. Where the labor item will not be considered in the cost of operating brooders, the most economical brooder will depend on the comparative cost of fuels at the place where the brooder is to be operated.

The ventilation of the brooder and brooder house is as important as the maintenance of a uniform brooding temperature. In the fuel-heated house the open fire removes large quantities of oxygen from the air and this must be replenished. In the electric brooder house no effort is made to heat the room and good ventilation is necessary to assist in keeping the litter in good condition.

The operating results with the converted electric brooder indicated that there is nothing to be gained by trying to convert old hovers into electric brooders. The increased current consumption soon makes up for the lower cost of rebuilding the brooder.

The home-made electric brooder, a plan of which is included, gave good brooding results with an average current consumption. The tests indicate that the principle on which this brooder operates is a good one. The design is such that good ventilation is assured and the distribution of heat under the brooder is uniform. The total cost of a brooder of this type is approximately \$10, exclusive of labor.

No particular advantage could be noted in the operation of the commercial fan-type brooder over the standard commercial brooder. Although the mortality rate was slightly lower and the average weight per broiler produced was higher, these factors do not offset the increased investment and cost of operation.

During the coldest weather the floors under the litter, and especially under the hovers of the electric brooders, had a tendency to become damp. This was probably due to the prolonged damp weather and to insufficient ventilation during these periods. No ill effects on the chicks were noted as a result of this condition.

The firing of the wood and coal brooders, together with the handling of fuel and ashes, required considerably more time and labor than did other brooders. The kerosene brooder was second in labor requirements, but it was necessary to dismantle it twice during each of the three trials to remove soot.

The lowest temperature during the tests was 7° F. below zero, and the average outside temperature for the 10-week period was 29.7°. This test indicates that a well-insulated electric brooder will give good brooding results in an unheated brooder house in the coldest weather that is likely to occur in Virginia.

Methods of heating hotbeds, G. J. STOUT, J. E. NICHOLAS, W. B. MACK, and D. C. SPRAGUE (*Pennsylvania Sta. Bul.* 338 (1936), pp. 22, figs. 10).—This summarizes experiments conducted for 3 yr. on the heating of hotbeds by electricity, anthracite coal, kerosene, manufactured gas, and fermenting manure.

Vegetable plants of satisfactory quality were grown in hotbeds heated by each of these means, and all are deemed practicable if properly installed. The most important differences were economic, in cost of installation and operation and in convenience and dependability. Proper insulation and weather stripping of electrically heated frames reduced energy consumption approximately one-half as compared with similar frames not insulated or

weather-stripped. Electrical energy consumption differed nearly 400 percent among the several methods of installation studied.

Coal heating is probably better adapted for the use of large commercial gardeners than for home gardeners and small commercial growers because of the cost of installation and because the commercial heaters are larger than is necessary for hotbeds less than 200 sq. ft. in area. The advantages of this method of heating are a relatively low cost of fuel and convenience of maintenance.

The commercial use of kerosene or gas must await the development of burners suitable for this purpose.

Manure is probably the cheapest means of hotbed heating for many farmers, especially where the fertilizing and soil improving value of the spent manure is considered. It is generally available on farms and, when properly managed, supplies plant food and maintains a steady heat. The chief disadvantage is that considerable care and skill are required for its most efficient use.

Effect of treatment on fence posts, J. C. WOOLEY (*Missouri Sta. Bul. 374* (1937), pp. 12, figs. 4).—This bulletin presents the results of tests of 21 posts of 27 different varieties of post timber which were begun in 1913. Six different treatments were used.

Setting in screened gravel increased the serviceable life of fence posts 10 percent, although 22 varieties failed. Some varieties were more favorably affected than others. Honeylocust showed an increase of 100 percent, red oak 90, and black locust 59 percent, while white oak, black walnut, and a few other varieties were unfavorably affected by the treatment.

Charring for a distance of 4 ft. up from the base resulted in an increase of 4.4 percent in the serviceable life of the posts. Black locust showed an increase of 90 percent, but the oaks and walnuts seemed to be unfavorably affected by charring. On the whole, the practice did not show sufficient gains to make it worth while.

There was an average increase of 55.4 percent in the serviceable life of posts painted with 2 hot coats of carbolineum. The varieties showing the greatest gain from the treatment were honeylocust 218 percent, red oak 166, hackberry 160, ironwood 160, black oak 131, and black locust 89 percent.

On painting with 2 hot coats of creosote, honeylocust showed a gain of 59 percent, white oak 15 percent, and other common varieties practically no gain from the treatment. Very little penetration was secured with the creosote applied with the brush.

Submergence to a depth of 4 ft. for an hour each in boiling and cold creosote resulted in an average gain in 21 varieties of 10.7 percent. The gain on the varieties most favorably affected with the percentage gain over the check was willow 300 percent, black ash 238, red oak 230, ironwood 227, honeylocust 176, river birch 166, hickory 155, cottonwood 150, black walnut 112, and white oak 21 percent. The real test, however, was the cost per post year, and many of these varieties showed too high a post year cost to be economical.

The average gain in 19 varieties from submergence for 2.5 hr. each in hot and cold creosote was 131.3 percent. The varieties most favorably affected were red oak 300 percent, willow 312, ironwood 300, black ash 293, hackberry 230, hickory 228, river birch 222, cottonwood 140, honeylocust 135, black walnut 89, and white oak 30 percent.

Osage-orange posts were economical without treatment, although they are not well adapted for board fences on account of difficulty of nailing. Catalpa and white cedar posts also proved economical without treatment.

Black locust posts cost slightly less per year without treatment, but about the same for the post year when treated with carbolineum. White oak was

found satisfactory without treatment, but was most economical with the carbolineum. Sassafras was found satisfactory without treatment but showed some increase in economy with the carbolineum. White walnut should be given the carbolineum treatment to give sufficient life to be economical. White elm proved economical only when given the carbolineum treatment, and honeylocust was economical only when treated with carbolineum or creosote.

Electric fence as a control for livestock (*Oklahoma Sta. [Blen.] Rpt. 1935-36, pp. 175, 176*).—Progress results of investigations are briefly presented.

A study of the southern farm home in relation to comfort, J. W. SIMONS and F. B. LANHAM (*Agr. Engin., 18 (1937), No. 1, pp. 9, 10, 14, figs. 2*).—This is a brief description of the plan of a study which is being conducted cooperatively by the U. S. D. A. Bureau of Agricultural Engineering and the University of Georgia to develop more satisfactory types of low cost construction for farmhouses. The immediate objectives are to determine temperature, humidity, air motion, and lighting conditions in farmhouses; to evaluate the absorption of solar radiation and atmospheric heat by farm buildings; and to devise inexpensive structural means, including the utilization of agricultural byproducts and wastes, for maintaining satisfactory temperatures, humidity, and air-motion conditions in farmhouses and farm buildings.

AGRICULTURAL ECONOMICS

Proceedings of conference on statistical methods of sampling agricultural data (*U. S. Dept. Agr., Bur. Agr. Econ., 1936, pp. 82*).—Included are the following papers or summaries of papers presented at the conference of the Bureau and the departments of agricultural economics and mathematics and the statistical laboratory of Iowa State College, held at Ames, Iowa, July 14-17, 1936: Need for an Annual Sample Census of American Agriculture and Type of Data Desired by the Farm Credit Administration, by O. A. Day (pp. 3, 4); Sample Census of American Agriculture Type and Need From Census Standpoint, by Z. R. Pettet (pp. 4-7); Sample Census of American Agriculture, by W. W. Wilcox (pp. 7-9); Sample Census of American Agriculture—the Type of Data Required and the Need for an Annual Sample Census, by J. A. Becker (pp. 9-11); Problem of Selecting the Sample—Experience of Iowa State College in Selecting Farms, Sampling Used, and Results Obtained, by T. W. Schultz (pp. 11-14); Statistical Problems of an Annual Sample Census of American Agriculture, by C. F. Sarle (pp. 14-21); A Sample Farm Census in Alabama, by H. H. Schutz (pp. 21-27); Rural Carrier Acreage Survey in Ohio, by C. F. Sarle (pp. 28-31); Assessor's and Rural-Carrier Acreage Data in Iowa, by L. M. Carl (pp. 32, 33); Summarization of Experience of Division of Crop and Livestock Estimates With Individual Farm Data, by J. A. Becker (pp. 33, 34); Sample Census of American Agriculture, by W. H. Ebling (pp. 34-36) and by M. M. Justin (pp. 36, 37); Problems of a Sample Census, by G. W. Snedecor (p. 38); Problems of Assessor Enumerations—Iowa Experience, by C. D. Reed (pp. 39-43); Wisconsin's Experience With Assessors' Enumerations, by W. H. Ebling (pp. 43-46); Kansas Assessors' Enumeration, by H. L. Collins (pp. 46-48); Indiana Assessors' Enumerations, by M. M. Justin (pp. 49, 50); Problems of Assessors' Enumerations (pp. 51-53) and Air Photographs (pp. 53, 54), both by Z. R. Pettet; Objective Measurements in Crop and Livestock Estimation—Crop Meter, Cotton Boll Count, Measurement of Size of Cotton Boll, etc., by J. A. Becker (pp. 54-60); and Problems Arising in Connection with Taking an Annual Sample Census of American Agriculture, by C. F. Sarle (pp. 61-80).

The report and recommendations of the conference are included.

[Investigations in agricultural economics by the Florida Station, 1935-36] (*Florida Sta. Rpt. 1936*, pp. 30-35).—Results of investigations not previously noted are included as follows: Tables showing costs by items, returns, and other data for midseason oranges for the years 1932-33, 1933-34, and 1934-35, found by C. V. Noble, Z. Savage, and B. McKinley in a study of cost of production and grove organization of Florida citrus; some preliminary data as to methods of sales, prices, and cost of marketing found in a study of the effects of precooling and refrigeration on cost of marketing, quality, and price of citrus fruits, by A. H. Spurlock, Savage, and McKinley, in cooperation with the U. S. Farm Credit Administration; a table by Noble showing by years, 1928-32, the number of farms, acreage, assessed valuation, and amount of delinquent taxes in six counties; and the principal conclusions arrived at in regard to citrus, trucking, and general farming areas and specialized dairy and poultry farms in a study of farm adjustments and type-of-farming areas from the standpoint of agricultural adjustment and planning, by Noble and McKinley, in cooperation with the U. S. D. A. Agricultural Adjustment Administration and Bureau of Agricultural Economics.

[Investigations in agricultural economics by the Maine Station, 1935-36] (*Maine Sta. Bul. 38½* (1936), pp. 408-427).—In addition to results previously noted, data are included on the condition of buildings, type of roads, slope and utilization of lands, use of electricity, number of telephones, and classification of land, as found in a study of local market areas by C. H. Merchant and A. E. Watson; the costs of producing potatoes in Aroostook County (E. S. R., 75, p. 411); and as to the cost in 1934 of maintaining work horses and standard and general-purpose tractors on 90 central-Maine potato farms.

[Investigations in agricultural economics by the Oklahoma Station, 1934-36] (*Oklahoma Sta. [Blen.] Rpt. 1935-36*, pp. 121-138, figs. 5).—Results not previously noted include tables and text showing the average yearly labor income and rate earned by Garfield County farmers, 1929-35; effects of tenure status of operators on farm organization in the Stillwater Creek soil conservation project; relation of New York and Liverpool prices of cotton and of cotton prices to demand; relation of volume of business and number of patrons to net income and the side line business to the success of cooperative elevators; and numbers and amounts of farm chattel mortgages filed in 11 counties during the year ended October 31, 1934, and in Payne County, 1927-36, and the relation of the latter to farm cash income.

Current Farm Economics, [February 1937] (*Oklahoma Sta., Cur. Farm Econ.*, 10 (1937), No. 1, pp. 24, figs. 2).—In addition to the usual tables of index numbers, articles are included as follows: Rural Zoning as a Means of Land Use Control in Oklahoma, by M. M. Blair (pp. 2, 3); Comparative Tax Load on Adjacent Farm Lands in Oklahoma and Surrounding States, by L. D. Melton (pp. 4-7); The New York Price of American Cotton is Closely Related to Prices at Other Futures Exchanges, by T. R. Hedges (pp. 7-13); Information on Soil Conservation, by P. Nelson (pp. 13-15); Possibilities of Cutting the Profit Margin Through Cooperative Enterprises, by A. L. Larson (pp. 15-17); Marketing Progress of One-Variety Cotton in Oklahoma and Other States, by C. B. Barre (pp. 17-20); and The Agricultural Situation, by T. R. Hedges (pp. 21, 22).

[Investigations in agricultural economics by the South Carolina Station, 1935-36] (*South Carolina Sta. Rpt. 1936*, pp. 9-15, figs. 3).—Included are findings as to (1) average labor income on the best farms and typical farms in a survey of farms in Greenville and Spartanburg Counties, by J. L. Fulmer; (2) some comparisons of the number of persons paying and amounts paid, and

the percentage of income absorbed by direct and income taxes in the years 1929-34, inclusive, and of the relation of assessed and actual value of farm real estate, by G. H. Aull and E. Riley; (3) the amount per acre of accumulated unpaid delinquent taxes on farm real estate in each year 1928-32 in 18 representative counties, found by Aull and Riley in a study in cooperation with the U. S. D. A. Bureau of Agricultural Economics and the Federal Emergency Relief Administration; and (4) a chart, by H. A. White, showing the percentages of various staple lengths of cotton produced in South Carolina, 1928-35.

[Investigations in agricultural economics by the Utah Station, 1934-36] (*Utah Sta. Bul.* 276 (1936), pp. 75-79).—In addition to results previously noted, brief summaries are given of some of the findings by W. P. Thomas, W. U. Fuhrman, and G. T. Blanch in a study of types of farming best adapted to Utah, and by Thomas and Fuhrman in a study of rural tax delinquency.

Foreign Agriculture, [January and February 1937] (*U. S. Dept. Agr., Bur. Agr. Econ., Foreign Agr.*, 1 (1937), Nos. 1, pp. 50, figs. 11; 2, pp. 51-100) — This monthly review of foreign farm policy, production, and trade will include "primarily the kind of material that has been embodied in the feature articles formerly appearing in *Foreign Crops and Markets*. The field that will be covered by these articles will, in general, fall within three broad classifications, (1) foreign government policies relating to agriculture, (2) foreign agricultural production, and (3) international trade in agricultural products." The articles "will consist largely of the results of special research or investigation conducted by the Washington staff or foreign field offices of the Bureau of Agricultural Economics and other bureaus of the Department of Agriculture, and adaptations from outstanding reports from American Consular offices. In addition, each issue will include a number of brief notes on outstanding developments in the foreign agricultural economic field."

No. 1 includes articles on Recent Developments in Soviet Agriculture, by L. Volin (pp. 3-28); Cotton Production in the State of Sao Paulo, Brazil, adapted from a report by P. O. Nyhus (pp. 29-42); and Agriculture in the German-Canadian Trade Agreements, based on a report by L. V. Steere (pp. 43-47); and miscellaneous notes on the results of dairy relief measures in the Netherlands, German fats and oils program, crop and livestock insurance in Bulgaria, and proposed distribution in Panama of land to poor farmers.

No. 2 includes articles on Danish Land Legislation, an Appraisal of Recent Trends, adapted from a report by J. W. Gannaway, Jr. (pp. 53-66); South African Agricultural Policy, by A. T. Murray (pp. 67-86); and Farm Relief Measures in the Netherlands, by H. E. Reed (pp. 87-97); and notes on adoption in Germany of new livestock regulations, proposed collective bargaining for French agricultural workers, and land tenure and agricultural labor in Chile.

A graphic summary of farm tenure (based largely on the census of 1930 and 1935), H. A. TURNER (*U. S. Dept. Agr., Misc. Pub.* 261 (1936), pp. [2]-52, figs. 71).—This is one of a projected series of 10 publications prepared under the general direction of O. E. Baker for the purpose of bringing the graphic summary of American agriculture (*El. S. R.*, 66, p. 477) up to date. These publications will be based on the 1930 and 1935 census reports and annual estimates of the Bureau of Agricultural Economics and will devote more attention to the economic and social conditions than the previous publications.

This publication was prepared in cooperation with the Resettlement Administration.

Land transfers in Cass County, North Dakota, 1875-1935, a period of sixty-one years, J. W. PORTER (*North Dakota Sta.*, 1936, pp. [13], figs. 4).—This study was made in cooperation with the U. S. D. A. Bureau of Agricultural Economics. Consideration was given to 33,430 deeds involving over 9,000,000 acres of land.

The number of transfers per year varied from 1,042 in 1882 to 263 in 1915. The transfers by different types of deeds were warranty 59.7 percent, quit claim 14.2, patents 17.2, sheriff's deeds 4.3, final decrees of distribution 3.2, and other 1.4 percent. Increasing population had little effect on average price per acre. There was little relation between size of purchase for full and true consideration and price per acre. No significant correlation between business activity in the United States and average price per acre during the period was noted.

Acquiring farm ownership by payments in kind, O. R. JOHNSON (*Missouri Sta. Bul.* 378 (1937), pp. 12, figs. 4).—A plan is outlined "to permit tenants to buy farms through annual product payments."

Incidence of the processing taxes under the Agricultural Adjustment Act: A selected list of references, compiled by L. O. BERCAW (*U. S. Dept. Agr., Bur. Agr. Econ., Agr. Econ. Bibliog.*, 68 (1937), pp. IV+46).—"This is an annotated, classified bibliography of selected references to books, pamphlets, and periodical articles on the incidence of the processing taxes imposed under the Agricultural Adjustment Act." The classification is made by commodities.

Rural tax delinquency in Pennsylvania, 1928-1932, P. I. WHIGLEY (*Pennsylvania Sta., Jour. Ser. Paper* 703 (1935), pp. [21]; *abs. in Pennsylvania Sta. Bul.* 336 (1936), p. 17).—In cooperation with the U. S. D. A. Bureau of Agricultural Economics and the Civil Works Administration, complete records for 45 counties and partial records for 5 counties were obtained of the rural tax delinquency, 1928-32. In the analysis the counties are grouped by geographical location and character of the region, productivity of land, and average farm income.

In general, counties with the most intensive agriculture had the least delinquency both in proportion to the value of land and number of farms but a greater percentage of increase. In May 1933, approximately 20 percent of the farms were tax-delinquent and delinquency was 6½ times as great as in May 1929. The average delinquency in 1932 was approximately \$20 per farm for all farms assessed.

The correlation of soil erosion and tax delinquency in the Piedmont area of South Carolina, B. M. LATHAM (*U. S. Dept. Agr., Soil Conserv. Serv.*, 1936, *SCS-RB-1*, pp. 22, figs. 2).—Surveys were made in selected rural school districts in 13 counties in the Piedmont section of the State. The lands in each district were divided into two groups—the less and the more or badly eroded soils. Tables and charts show for each district for each group for the years 1928-32, inclusive, the percentages of properties, acres, and taxes delinquent, assessed valuation per acre, and the average (1928-32) number of properties, size of farm, and taxes paid per farm. The surveys for each county showed a positive correlation between soil erosion and tax delinquency.

Crop insurance: Selections and excerpts (*U. S. Dept. Agr., Bur. Agr. Econ.*, 1936, pp. [21]+26).—Included are excerpts from the bulletin previously noted (*E. S. R.*, 46, p. 787) on the history prior to 1922 and principles involved in crop insurance; an article by V. N. Valgren in 1925 on Insurance and the Farm Hazards;* and an address by the Secretary of Agriculture, H. A. Wallace, July 22, 1936. Also included are the letter of President Roosevelt

* *Jour. Land and Pub. Util. Econ.*, 1 (1925), No. 2, pp. 189-197.

to Secretary Wallace on September 19, 1936, appointing a committee to prepare a report and recommendations for legislation providing a plan of "all risk" crop insurance; and an address of R. M. Green on October 13, 1936, outlining the history of the crop insurance movement since 1922 and dealing with some of the problems involved.

The farm outlook for 1937 (*U. S. Dept. Agr., Misc. Pub. 255 (1936), pp. IV+44, figs. 18*).—Continuing the series (*E. S. R., 74, p. 554*), "this publication summarizes the principal facts and conclusions of the thirteenth annual Agricultural Outlook Report prepared by the Bureau of Agricultural Economics in cooperation with representatives of the State agricultural colleges." The general outlook as regards domestic and foreign demand for farm products, prices for farm products, farm credit, taxes, farm labor, prices of building materials, farm machinery, and fertilizer, and farm family living is discussed. More detailed analysis is made of the outlook for cotton, wheat, tobacco, fruits, truck crops, sweetpotatoes, potatoes, rice, flaxseed, clover and alfalfa seed, peanuts, dry beans, tree nuts, feed grains, hay, pastures, commercial feedstuffs, hogs, beef cattle, sheep and lambs, wool, mohair, dairy products, chickens and eggs, turkeys, and horses and mules.

Agricultural outlook charts, 1937 (*U. S. Dept. Agr., Bur. Agr. Econ., 1936, [1], pp. [6]+17, figs. 22; [2], pp. [6]+27, figs. 29; [3], pp. [5]+13, figs. 25; [4], pp. [6]+53, figs. 32; [5], pp. [3]+27, figs. 13; [6], pp. [6]+26, figs. 21; [7], pp. [6]+19, figs. 22; [8], pp. [53], figs. 68; [9], pp. [4]+15, figs. 15; [10], pp. [6]+35, figs. 45; [11], pp. [54], figs. 32; [12], pp. [4]+11, figs. 14; [13], pp. [4]+21, figs. 21; [14], pp. [4]+19, figs. 17; [15], pp. [37], figs. 31; [price list], pp. 32*).—These books of charts which supplement the outlook report above noted "have been selected by the Outlook Committees as those best adapted for presenting graphically the economic background for the respective commodities." The series includes beef cattle; cotton; dairy products; demand, credit, and prices; farm family living and summaries; feed crops (corn, oats, barley, hay) and total livestock; flaxseed, soybeans, peanuts, and cottonseed; fruits and nuts; hogs; potatoes and truck crops; poultry and eggs; rice, dry beans, and broomcorn; sheep, lambs, and wool; tobacco; and wheat and rye.

A price list of charts on different subjects suitable for outlook meetings and field meetings of farmers is also included.

An analysis of agriculture on the Valier irrigation project, P. L. SLAGS-VOLD (*Montana Sta. Bul. 330 (1936), pp. 47, figs. 19*).—This study was made to obtain an inventory of the physical and economic resources of the project and to suggest a method of farm organization analysis which may be helpful in bringing about a more stable agriculture. The development and present status of the project and its physical and economic characteristics are described. Analysis is made of the trends in crops grown, yields, number of livestock, farm ownership and tenancy, etc., on the project. Suggested budgets are included for an 80-acre and a 160-acre farm.

A land classification program for the agricultural lands of Oregon ([Salem]: *Oreg. Planning Council, 1934, pp. [1]+24*).—Procedure is suggested for collecting and analyzing the physical and economic data necessary as a basis for a land classification program. Tables show the estimated cost of a 5-yr. program and the status in 1934 of the different studies.

Cattle ranching and range utilization in western North Dakota, M. B. JOHNSON and R. D. JENNINGS (*U. S. Dept. Agr., 1937, pp. 96, figs. 7*).—This study, which is cooperative with the North Dakota Experiment Station and Extension Service, supplements that previously noted (*E. S. R., 63, p. 884*), and was made to ascertain the organization of beef cattle ranches and the ownership and use of grazing and croplands in western North Dakota. It is based on data secured

regarding 35 ranches in 1931 and 30 in 1932 and a study of 3 sample areas containing 864 sq. miles. The variations in ranch organization are discussed, and examples of representative ranches in the 3 classes of ranches are described. Range management and land utilization and range control in the area are discussed.

Some characteristics of cultivatable land in the sugar cane area of Louisiana, R. J. SAVILLE and A. L. DUGAS (*Louisiana Sta. Bul.* 280 (1936), pp. 47, pl. 1, figs. 3).—“This report, largely statistical in content, presents some characteristics of the land and its present and potential uses as found by a survey in 13 parishes forming the heart of the ‘Sugar Bowl.’” The data were obtained through interviews with the owners and operators of 6,872 tracts, the work being done in cooperation with the Emergency Relief Administration of Louisiana and the Works Progress Administration. In making the analysis of land use, size of tracts, cultivatable acreage, present sugarcane acreage, yields, production, man-labor and work stock efficiency, regular and extra workers, etc., the tracts were divided into three classes on the basis of percentage of cultivatable land idle in 1934 and into size groups of from 1 to 99.9 acres, 100 to 999.9 acres, and 1,000 acres or more. Land ownership and milling and transportation facilities in the area are described.

Of the cultivatable land, 20 percent was idle in 1934. Sugarcane was the last previous crop on 49 percent of the idle land, rice on 15 percent, and cotton on 1.2 percent. In the period 1925–29, 49.1 percent became idle, and 19.3 percent in the period 1930–34. A desired acreage increase in sugarcane of 95.9 percent (198,188 acres) was shown by the reports obtained in the study, the proportions of increase for the different classes of land being no idle land 16 percent, all idle 14 percent, and partly idle 70 percent. The average yields of sugarcane per acre were 12, 12.8, and 13.3 tons, respectively, on the small, medium size, and large tracts. The yields were highest on tracts having no idle land. An increase in acreage of sugarcane to the desired level would require an increase of approximately 13,459 regular workers, an increase of 125 percent of the extra workers required for hoeing, and of 91 percent of those for harvesting. A considerable expansion in capital goods, mostly local products, would also be required.

Grade and staple length of cotton produced in Louisiana, 1928–34, W. B. LANHAM, C. C. McWHORTER, and L. M. SKINNER (*U. S. Dept. Agr., Bur. Agr. Econ.*, 1936, pp. [2]+41, figs. 16).—This study was made in cooperation with the Louisiana Experiment Station. Tables, maps, and charts are included and discussed, showing the grades and staple lengths produced in the United States and each of the 4 sections and 16 subsections of Louisiana, the quality of cotton ginned in Louisiana during different periods of the cotton season, and the premiums and discounts for grade and staple length in central and local markets.

About 77 percent of the Louisiana cotton during the period was extra white or white in color and middling or better in grade and 42 percent was 1 in. or longer in staple length, as compared with 69 and 26 percent, respectively, for the United States. Of the ginnings prior to October 1, 37 percent were extra white middling or better as compared with 26 percent of the ginnings after January 15. The percentages of ginnings 1 in. or more in length were: Prior to October 1, 44; October and November, 38; December 1 to January 15, 40; and after January 15, 50. New Orleans market quotations per bale for the year beginning August 1, 1934, for good middling white $\frac{3}{8}$ -in. cotton averaged \$2.25 higher than for middling $\frac{3}{8}$ -in. and \$9.85 higher than for good ordinary cotton. Middling white $1\frac{1}{8}$ -in. cotton was worth \$8.85 per bale more than $\frac{3}{8}$ -in. and \$10.85 more than $1\frac{3}{8}$ -in. similar cotton.

Wheat futures (*U. S. Dept. Agr., Statis. Bul. 54* (1937), pp. 108, figs. 4).—This bulletin continues the series previously noted (*E. S. R.*, 70, p. 708) by presenting data on the volume of trading, open commitments, and prices from January 3, 1933, to December 31, 1935.

Cost of production of tomatoes: Data from studies in 20 States, selected years, 1913-34, compiled by H. W. HAWTHORNE (*U. S. Dept. Agr., Bur. Agr. Econ., 1936*, pp. 43).—Data pertaining to cost of production found in studies by the Department, State experiment stations, and other agencies in 20 States from 1913 to 1934, inclusive, are presented.

Cost of production of citrus fruits: Data from studies in California and Florida, selected years, 1917-35, compiled by H. W. HAWTHORNE (*U. S. Dept. Agr., Bur. Agr. Econ., 1936*, pp. 60).—Data are compiled from reports of the Bureau of Agricultural Economics as to the average production, 1930-34, of different citrus fruits in different States; as to number of trees and acreage by age groups in Arizona, Florida, and Texas in 1934 or 1935; and as to costs of production found in studies made by the Department, State experiment stations, and other agencies from 1917 to 1935.

Florida truck crop competition.—I, Inter-State and foreign, C. V. NOBLE and M. A. BROOKER (*Florida Sta. Bul. 224, Sups. (1934)*, pp. [26]; (1935), pp. [27]; (1936), pp. [25]).—These supplements (*E. S. R.*, 65, p. 886) include tables showing the weekly carlot shipments during the 1933-34, 1934-35, and 1935-36 crop seasons for different truck crops.

Charleston as a market for fruits and vegetables, W. W. ARMENTROUT (*West Virginia Sta. Bul. 279* (1937), pp. 40).—This study was made to secure data concerning opportunities for marketing fruits, vegetables, and other farm produce as a guide in formulating agricultural production plans in connection with the Red House Homestead, a resettlement colony of the West Virginia Relief Administration. Analysis is made of the daily freight receipts for the years 1931-33, inclusive, and from January 1 to October 31, 1934, and of the sales and prices in the Patrick Street market during the summer of 1934. Tables show by semimonthly periods the receipts of the principal products by State of origin and other data. No attempt is made to predict future demand.

The Philadelphia fruit and vegetable market, F. P. WEAVER and F. F. LININGER (*Pennsylvania Sta. Bul. 336* (1936), p. 16).—A brief statement is made as to findings in regard to the proportion of produce not passing through the Dock and Callowhill Streets wholesale markets and the produce sold by farmers through commission men.

Produce marketing in Reading and Wilkes-Barre, Pennsylvania, R. B. DONALDSON and J. GAUSS (*Pennsylvania Sta., Jour. Ser. Paper 720* (1936), pp. [2]+34; *abs. in Pennsylvania Sta. Bul. 336* (1936), p. 17).—This is a study of the sources of supply, methods of transportation, and types of outlets to consumers in the two areas during 1932.

Marketing problems in the apple industry.—Preliminary considerations (*U. S. Dept. Agr., Agr. Adjust. Admin., Gen. Crops Sect., 1936*, pp. [2]+35, figs. 6; pp. [2]+19, figs. 3; pp. [2]+10, fig. 1; pp. [2]+20, figs. 5).—These four studies discuss the trend in production and prices, competition of different sections and with other fruits, storage, foreign trade, factors affecting prices, etc. The first, by N. L. Gold, deals with the national situation; the second, by R. P. Callaway, with the eastern situation; the third, by C. I. Tod, with the central situation; and the fourth, by Gold, with the western situation.

An economic study of milk production costs in herds of producer-distributors in Maine, G. F. DOW (*Maine Sta. Bul. 385* (1936), pp. 51, figs. 4).—This bulletin is based on data regarding production costs for the year ended April 30, 1935, from 108 producer-distributors in the Portland, Waterville, and

Bangor areas. Analysis is made of the effects on production costs of feed costs, man labor, use of buildings and dairy equipment, production per cow, size of herd, cow replacements, breed of cattle, butterfat content of milk, purebred v. grade cows, depreciation on cows, etc. The areas, utilization of milk, and dairy farm organizations are described and comparisons made of the production costs of producer-distributors and producer-wholesalers in the Portland area, and of production costs in the areas studied and the areas supplying Boston.

The average net cost of production in the Portland area was \$2.55 per hundredweight of milk and \$2.20 in the three areas combined. The costs for the Portland market are approximately 0.5 ct. higher per quart than in the areas supplying Boston.

Of the total production costs, feed comprised 58.2 and man labor 22.3 percent. Total costs increased about 0.25 ct. per quart for each increase of 0.3 percent in the butterfat test. Cows producing 5,000 lb. of milk annually were fed on the basis of 1 lb. of grain to every 2.8 lb. of milk produced, those producing 8,000 lb. on the basis of 1 lb. to 3.2 lb. of milk. The costs per hundredweight of 4 percent milk in 15 herds producing less than 5,000 lb. of milk per cow was \$2.69 as compared with \$1.68 in 10 herds producing over 9,000 lb. per cow. Costs decreased from \$2.28 per 100 lb. of milk in herds of 20 or more cows to \$2.06 in herds of under 15 cows.

Transportation of milk and cream to the New York market, H. R. VARNEY ([*New York*] *Cornell Sta. Bul.* 655 (1936), pp. 79, figs. 15).—This study was made to ascertain the volume of milk and cream moving from country plants to plants in the New York metropolitan area, the methods of transportation used, the changes in such methods, the costs of hauling by truck, and some of the factors affecting such costs. The increase in the use of trucks and of tank cars and tank trucks and the advantages of such uses are described.

The receipts of milk by rail increased from 1885 to 1930, then decreased approximately 50 percent to 1935. Receipts by truck increased nearly 600 percent from 1930 to 1935 and in the latter year were approximately 85 percent of the receipts by rail. Production in the metropolitan area decreased over 54 percent from 1885 to 1930 and 1935. Receipts of cream and plain condensed milk by rail increased rapidly from 1885 to 1930, then decreased over 40 percent to 1935. Receipts by truck in 1935 were approximately 3.5 percent of those by rail. The average daily per capita consumption in the metropolitan area in 1934 and 1935 was 0.65 pt. of milk and 0.04 pt. of cream. The seasonal variations in the receipts of milk were about 16 percent in the period 1910-14 and 11 percent in the period 1930-34. Over 98 percent of the milk and 95 percent of the cream during the period 1927-35 was from New York, Pennsylvania, New Jersey, and Vermont. From 1927 to 1934, inclusive, the percentage of milk from New York decreased from 79 to 66 percent, that from Pennsylvania increased from 10 to 17, that from New Jersey from 7 to 11, and that from Vermont from 2 to 4 percent. The average cost of operating trucks, average load 1,722 gal., was 15.5 ct. per mile, of which nearly one-third was drivers' wages, one-fifth depreciation and interest, and 14 percent gasoline. During the year ended June 30, 1933, over one-third of the rail shipments was in tank cars.

Cost of delivering milk in small cities with different types of conveyances, T. M. OLSON (*South Dakota Sta. Rpt.* 1936, p. 20).—A brief comparison is made of the costs of delivery with horses and with trucks in the city of Brookings.

Cost of operating farm motor trucks on grain farms (Northern Great Plains and Pacific Northwest, 1933), R. S. WASHBURN (*U. S. Dept. Agr., Bur. Agr. Econ., 1936, pp. 15, fig. 1*).—Data obtained from 1,674 farm operators, chiefly for the 1933 crop year, are analyzed and discussed. Tables show the number and size of, and crops produced on, farms with and without motor trucks by different types of farming areas, and the average costs by items in operating trucks of different sizes.

The farmer's share of the consumer's food dollar (U. S. Dept. Agr. Leaflet 123 (1937), pp. 11+6, figs. 2).—Tables and charts are included showing by years, 1913-35, the retail and farm values, percentage of retail value received by farmers and for transportation, processing, marketing, and distribution, and amounts spent by consumers and received by farmers for 58 food products; the retail prices and prices paid producers for selected products in 1935; and food margins and wage rates, 1913-35. The technical study was conducted by R. O. BEEN and F. V. WAUGH, and the leaflet prepared by C. B. SHERMAN. "In general it appears that the increased charges have been about in line with the increased costs, including processing taxes and higher wage rates."

Agricultural cooperative organizations in California (California Sta. Mimeogr. Rpt. 56, pp. [1]+16).—This is a list of these associations showing by counties the associations, their addresses, and commodities handled.

Farm value, gross income, and cash income from farm production, 1934-1935 (U. S. Dept. Agr., Bur. Agr. Econ., Crop Rptg. Bd., 1936, pp. [2]+100).—The data are shown by States and commodities.

Index numbers of production, prices, and income, J. I. FALCONER (Ohio Sta. Bimo. Bul. 184 (1937), p. 40).—This table (E. S. R., 76, p. 551) is brought down through October 1936.

Farm production and income from meat animals, 1924-1935 (U. S. Dept. Agr., Bur. Agr. Econ., 1936, pp. [2]+135).—"This report contains estimates of inventory numbers of meat animals and production, farm disposition, marketings, local prices, value, and income. The data are shown by States for the entire period, 1924 to 1935, for which such data are available."

Statistics relating to international trade in cotton and linters, 1921-1935, C. G. GILES and A. T. TURNER (U. S. Dept. Agr., Bur. Agr. Econ., 1936, F. S. 67, pp. [2]+89).—"This publication presents in detail the export and import trade in unmanufactured cotton from 1921-1935 for all countries in which such trade is significant. As of additional value, average exports and imports for 1909-1913 have also been included in the summary tables. . . . These statistics have been taken from the official publications of the various countries, supplemented in a few cases by reports from United States representatives abroad."

Cotton revisions: Acreage, yield, and production, crop years 1866-1935 (U. S. Dept. Agr., Bur. Agr. Econ., Crop Rptg. Bd., 1936, pp. [1]+34).—Tables prepared by the Crop Reporting Board show for the United States as a whole, by States, and for Lower California by years the acreages of cotton harvested, yields per acre, production of lint cotton and seed, and beginning in 1899 the ginnings reported by the Bureau of the Census.

Carlot shipments and unloads of nineteen important fruits and vegetables for the calendar years 1933 and 1934 (U. S. Dept. Agr., Statist. Bul. 53 (1936), pp. 206).—This bulletin supplements that previously noted (E. S. R., 72, p. 860) and shows the shipments by State of origin and by months, the relation of such shipments to shipments of all fruits and vegetables, and the unloads in 66 cities.

Relationships among watermelon prices, freight rates, production, and marketings, G. BUMMEISTER and T. HULTGREEN (U. S. Dept. Agr., Bur. Agr.

Econ., 1936, pp. 33, pls. 10).—Tables and charts present data by years, usually 1925-35, as to acreages and production of watermelons in the United States, prices in New York City and Chicago, and the freight charges to these cities from important growing areas. Other tables include data by years, usually 1928-35, as to acreages, production, average farm price and value, freight revenues, etc., of cabbage, potatoes, melons other than watermelons, onions, tomatoes, and berries.

Apples: Yields, prices, returns per acre, and trend in plantings of important varieties of apples grown in selected districts of the East (Virginia, West Virginia, Maryland, Pennsylvania, and Delaware), W. H. YOUNGMAN, R. P. MATTESON, C. J. BLAIR, JR., and J. A. P. SAUNDERS (*U. S. Dept. Agr., Bur. Agr. Econ.*, 1936, pp. 55, figs. 5).—This study was made in 1934 in cooperation with the U. S. Farm Credit Administration "to determine for each variety of major importance the yields, prices, and gross return per acre, as a basis for guiding growers in problems of orchard development and management."

Crops and Markets [January-February 1937] (U. S. Dept. Agr., Crops and Markets, 14 (1937), Nos. 1, pp. 20, figs. 2; 2, pp. 21-48, figs. 2).—Included are reports, summaries, charts, etc., covering crop and livestock estimates, market reports on livestock, livestock products, dairy and poultry products, feeds, seeds, grains, and cotton, and the price situation (No. 1 only) of important agricultural products. No. 2 includes the preliminary inventory as of January 1, 1937, of livestock on farms in the United States, with comparisons for 1935 and 1936.

RURAL SOCIOLOGY

Introduction to social research, E. S. BOGARDUS (*Los Angeles: Suttonhouse Ltd.*, [1936], pp. XI+237, figs. 17).—Various methods of social research are presented in convenient form.

[Investigations in rural sociology by the Oklahoma Station], O. D. DUNCAN (*Oklahoma Sta. [Bien.] Rpt. 1935-36*, pp. 138-140, fig. 1).—Data are given on the social aspects of farm life, size of farm family as a factor in living conditions, recent population movements in Oklahoma, and city to farm migration.

[Investigations in rural sociology by the Utah Station] (Utah Sta. Bul. 276 (1936), pp. 72-74).—Progress results are briefly reported on the historical background of the Utah village, the extent to which edge-of-town farm families use village agencies, and the dependence of social advancement on social qualities.

County planning and zoning: Lists of enabling acts and commissions, C. I. HENDRICKSON (*U. S. Dept. Agr., Bur. Agr. Econ.*, 1936, pp. 30, figs. 8).—This is an annotated list of the enabling acts and commissions for State, county, town, and township planning and zoning in the United States.

A preliminary report of land utilization of problem areas in North Dakota ([Fargo]: N. Dak. State Planning Bd., 1935, pp. [1]+9).—This is a brief general report by the consultant of the National Resources Board.

Preliminary report on State planning (Oklahoma City: Okla. State Planning Bd., 1936, pp. [12]+295, [pls. 83]).—This preliminary report includes chapters on the history, population, land use, occupations, industry, mineral resources, transportation, State public institutions, conservation by State departments, educational services by State departments, public improvements in Oklahoma, Federal agencies, relief, and planning in Oklahoma.

A compendium of maps and charts pertaining to State planning in Oklahoma (Oklahoma City: Okla. State Planning Bd., 1936, pp. 133, [pl. 1, figs. 65]).—This is a supplementary publication to that noted above.

The field of State planning, V. B. STANBERRY (*Portland: Oreg. State Planning Bd., 1936, pp. [2]+11*).—This paper was presented at the Third Pacific Northwest Regional Planning Conference at Spokane, Wash., February 13, 1936.

Social planning for Canada (*Toronto: Thomas Nelson & Sons, 1935, pp. [XV]+528, [fig. 1]*).—"Facts gleaned from many sources, not readily accessible to the public, have been assembled within the compass of one volume so as to give a comprehensive survey of conditions in Canada."

Social mobility in the farming occupation, B. O. WILLIAMS (*South Carolina Sta. Rpt. 1936, pp. 7-9*).—Data derived from a study of residential shifting among farmers in eight counties of the State are reported.

Rural population mobility in South Dakota, W. F. KUMLIEN (*South Dakota Sta. Rpt. 1936, pp. 44, 45*).—Some general findings in the study covering the years 1928-34, inclusive, in six counties representative of the more important types of farming areas are given.

Landlord-tenant relations and relief in Alabama, H. HOFFSOMMER (*[Auburn]: Ala. Relief Admin., 1935, pp. [3]+II+33, pl. 1*).—This report provides information on the relationships between landlords and tenants in the Alabama cotton region as of December 1933, especially as these relationships are associated with the administration of relief.

Roughly, 40 percent of the relief households were indebted to their landlords for debts of more than one year's standing. In a number of cases the exact amount of indebtedness was not known by the tenant. Over 90 percent of the 1,022 households questioned considered that they were better off on relief than they had been in recent years before the relief program was inaugurated. Current criticism that governmental programs designed to aid the sharecropper will ruin his powers of self-direction found no support in this survey, since the sharecroppers had already been pauperized more under the tenant system than would have been likely under any governmental arrangement.

The sharecroppers had profited little financially from agricultural adjustment payments since the bulk of the money received had passed on to the landlords in 60 percent of the cases.

Climbing the so-called "agricultural ladder" was largely a fiction for these families. Whereas only 9 percent of those who started out as croppers became owners, 8 percent of those who started out as owners became croppers.

The average tenure of sharecropper relief households was 3 yr. The Negro tenure was twice that of the white, and the average tenure of nonrelief tenants was longer than that of the relief.

Relation of education to social and economic status of farmers in Tennessee.—A preliminary report, C. E. ALLRED and B. D. RASKOFF (*Tennessee Sta., Agr. Econ. and Rural Sociol. Dept. Monog. 29 (1937), pp. III+84, figs. 17*).—In each of the counties studied the white farmers with high school and college education have smaller families than do those with less schooling. There is little relation between the size of Negro farm-owner families and the education of the family head, but among Negro tenants the better educated family heads have smaller families. Among the families studied Negro farmers have larger families than white farmers in every educational group. White farm operators with better education have more conveniences, literature, and music in the home than do farmers of little or no schooling. Negro farmers have little in the way of conveniences, literature, and music. In all but one county the better educated white and Negro farmers operate larger farms and have more capital invested, larger farm labor incomes, and a greater net worth than do farmers of little or no education.

Education of farmers' wives and children in four counties in Tennessee. C. E. ALLRED and B. D. BASKOFF (*Tennessee Sta., Agr. Econ. and Rural Sociol. Dept. Monog. 27* (1937), pp. IV+44, figs. 27).—In each of the four counties studied 66 percent or more of the wives of farm owners and tenants combined have not gone to high school and less than 7 percent have attended college. In Williamson County in 1920, 13.7 percent of the wives of white farm owners and 9.7 percent of the wives of white tenants reported no schooling, while in Madison County in the same year all the white farm owner and tenant wives had some schooling. In Overton County in 1936 about 7 percent of the wives of farm operators reported no formal education. Negro wives have less education than white wives of both farm owners and tenants, and Negro farm boys and girls have less schooling in every age group than white children. Children of white farm owners have superior education compared with children of white tenants, but among Negro farm children there seems to be little difference in educational status as to tenure.

Farm housing in Tennessee, with regional comparisons. C. E. ALLRED and W. E. HENDRIX (*Tennessee Sta., Agr. Econ. and Rural Sociol. Dept. Monog. 26* (1937), pp. II+45, figs. 25).—The average value of all farm dwellings in Tennessee in 1930 was \$602. Dwellings occupied by owners have an average value of more than twice that of tenant houses. The average number of rooms is 4.33. Nearly one-half of the houses are painted. White owners have an average of 5.02 rooms per dwelling compared with 3.92 for white tenants, 3.85 for colored owners, and 3.22 for colored tenants. A comparison indicates that "housing conditions in Tennessee are better than in either North Carolina or Arkansas. Farm dwellings in Iowa are better than those in the three southern States."

Rural youth: Activities, interests, and problems.—II, Unmarried young men and women, 15 to 29 years of age. W. A. ANDERSON ([*New York Cornell Sta. Bul. 661* (1937), pp. 36).—This second report (E. S. R., 75, p. 561) is based on data regarding 399 unmarried men and 359 unmarried women from 15 to 29 yr. of age, of whom 47 percent lived on farms, 34 percent in villages, and 19 percent in rural nonfarming territory.

Of the men, 40 percent were in school, 28 percent had full-time employment, and 22 percent part-time gainful work. For the women the percentages were 53, 15, and 8, respectively. More than 75 percent of the two groups had some high school or college training but about 75 percent had no vocational training for a specific occupation. Reading was the most important leisure-time activity. Membership in organizations averaged less than 1 for the men and slightly over 1 for the women. Of the men 56 percent and of the women 46 percent were not members of formal organizations. Forty percent of the entire group had no suggestions as to how the local communities could help young people.

Wisconsin rural youth: Education and occupation. J. A. JAMES and J. H. KOEHL (*Wisconsin Sta. Bul. 437* (1936), pp. 24, figs. 7).—Five sample counties were selected and studied during the fall and winter months of 1934 with regard to education and to occupation. In the five counties there were 10,250 persons in the age group 20-25 yr. in 1928, and education and school attendance information was secured for 9,279 in this group in 1934. Comparisons of the elementary education of the group indicate that 71 out of every 100 farm young men and 60 out of every 100 farm young women had not gone beyond an eighth grade education. Of the 5,217 persons who had an eighth grade education or less, 51.4 percent were farm boys and 37.6 percent were farm girls.

Farming and homemaking on the farm were the chief occupations of the rural youth who lived in the country in 1933, farming being followed by 73.6

percent of the farm young men whose homes were on the farm in 1928 and homemaking by 49.4 percent of the farm young women. Only 16.2 percent of the village young men and 8.8 percent of the village young women were similarly occupied. The data indicate that over half of the farm young women leave the farm for pursuits in village or city, 39.7 percent of whom are housewives and 25.7 percent are in domestic or personal service.

The opportunity and output of the rural high school and the influence of agricultural instruction in the high school are discussed.

AGRICULTURAL AND HOME ECONOMICS EDUCATION

Interpretive science and related information in vocational agriculture: Effective utilization of scientific principles and related information in organized agricultural instruction (*U. S. Dept. Int., Off. Ed., Vocat. Ed. Bul. 191 (1936), pp. V+27, pl. 1*).—"This publication is designed primarily to provide teachers of vocational agriculture with subject matter and illustrative material regarding the place and use of scientific principles and related information as interpretive material in the instruction process."

The three parts discuss the relationship between agriculture, science, and related information; organizing teaching content to provide for interpretive science and related information; and examples of some effective uses of interpretive science and related information during the instruction process.

A basis for a proposed course of study in agricultural economics and farm management for departments of vocational agriculture in Missouri, G. J. DIEFOLD (*Missouri State Bd. Vocat. Ed. Bul. 25 (1934), pp. 103, figs. 19*).—"The purpose of this study is to discover and report the outstanding problems in agricultural economics and farm management confronting farmers in Missouri in order that basis for a suitable course of study may be prepared for all day high school students in vocational agriculture." Data were obtained by questionnaires from teachers of vocational education, parents of students in such courses, all departments in the State having courses in agricultural economics and farm management, and former students in such courses. Expert opinions were solicited from agricultural economists in 12 States comparable to Missouri in agricultural conditions. Analysis is made of the replies of the economists, teachers, and farmers as to the importance of and from students as to the interest in the State objectives in pork, poultry, dairy, and beef cattle, sheep, fruit, corn, and wheat production and marketing, and of the replies of economists, teachers, and students as to the relative difficulty in State objectives in the different lines. Tables show the objectives in the several lines ranked on the basis of the findings in the analysis.

The general principles in course construction applied in the State are applied in the vocational departments in two cities representative of different situations. Teaching activities necessary to apply to the objectives set up in the study are discussed.

Dairy enterprises, J. C. McDOWELL and A. M. FIELD (*Chicago: J. B. Lipincott Co., [1936, rev. ed.], pp. VII+471, pls. 6, figs. [228]*).—This is a revised edition of the textbook previously noted (*E. S. R., 63, p. 889*).

The home economics omnibus, F. LAG. HARRIS and H. H. HUSTON (*Boston: Little, Brown & Co., 1935, pp. XIII+617, pl. 1, figs. 202*).—This volume covers the seven divisions of the standard home economics course in high schools, namely, foods and nutrition, clothing, home planning and furnishing, home management, child care and development, health, and family and other social relationships. To challenge the interest of the high school girl the text is written in an informal style and centers about the girl's life, with the subject matter presented under headings such as the well-fed family, the

well-dressed girl, and the well-bred girl and her social relationships. Suggestions for class activities are given at the end of each unit, and books and other references are listed at the end of each division.

The research and educational activities of the station as relating to agricultural trends in New Jersey, J. G. LIPMAN (*New Jersey Stat. Bul.* 616 (1936), pp. 20).—The participation of the stations in the economic and social life of the State during the author's connection therewith since 1896, and especially during the period from 1911 to date in which he was director of the stations, is described.

On the front lines with agriculture: A report of extension work in agriculture and home economics in 1934 (*U. S. Dept. Agr., Ext. Work Agr. and Home Econ. Rpt.*, 1934, pp. [2]+80).—In this report (E. S. R., 76, p. 269), the chief lines of work and the results obtained are discussed. Statistical tables (pp. 41-80) for finances and results are included, the former covering the year ended June 30 and the latter covering the year ended November 30, 1934.

The life and work of Seaman A. Knapp, R. CLINE (*Nashville, Tenn.: George Peabody Col. Teachers*, 1936, pp. [7]+110, pl. 1).—This biography (E. S. R., 24, p. 497) was prepared as a Ph. D. thesis in the George Peabody College for Teachers.

Workers in subjects pertaining to agriculture in State agricultural colleges and experiment stations, 1935-36, M. A. AGNEW (*U. S. Dept. Agr., Misc. Pub.* 234 (1936), pp. V+133).—This is the usual annual list (E. S. R., 73, p. 553) showing the workers in agriculture and home economics.

Workers in subjects pertaining to agriculture in land-grant colleges and experiment stations, 1936-37, M. A. AGNEW (*U. S. Dept. Agr., Misc. Pub.* 254 (1937), pp. V+135).—This is a list similar to that noted above.

FOODS—HUMAN NUTRITION

[Foods and nutrition studies at the Florida Station] (*Florida Sta. Rpt.* 1936, pp. 62, 63, 70-72, 79, 80).—In this annual report summaries, some of which cover an extension of work noted previously (E. S. R., 75, p. 717), are given by R. B. French on the vitamin C content of tomato, fresh celery leaves, and oranges; by H. W. Winsor on variations in the iron content of turnip and mustard greens grown on iron-deficient soils with and without fertilization; by C. F. Ahmann on the relation of growth to phosphorus, calcium, and lipid metabolism as influenced by the thymus and on the pathologic changes in the tissues of range animals suffering from "salt sick" and laboratory animals suffering from a deficiency of iron and copper before and after suitable therapy; by O. D. Abbott on the changes occurring in the white blood cells of adult rats in vitamin A deficiency and of malnourished adult humans before and after treatment with diets high in vitamin A and on the relation of anemia in the children of Alachua County to the iron content of home-grown foods; and by A. F. Camp and A. H. Stahl on the cold storage of citrus juices and quick-frozen citrus juices, strawberries, and Youngberries.

Foods and nutrition [studies at the Maine Station] (*Maine Sta. Bul.* 384 (1936), pp. 397-401).—This progress report (E. S. R., 75, p. 420) by M. M. Clayton includes some of the most outstanding results in the physical examination and diet survey of the food habits and nutritional status of children in selected communities in the State, and further data on the antiscorbutic value of home-canned pickles of various types.

Bread baking with dried yeast (*Wyoming Sta. Rpt.* 1936, pp. 13, 14).—A method developed at the station for bread making at high altitudes, using Wyoming hard wheat flour and dried yeast cakes, is described briefly.

The relative merits of the beater and whip and of size of mixing bowl on the results obtained with the A. A. C. C. basic cake-making method, H. R. FISHER (*Cereal Chem.*, 13 (1936), No. 5, pp. 603-606).—This paper and the three which follow are subcommittee reports on cake-baking tests.

The mixing bowls were of 3-qt. and 10-qt. capacities equipped with wire whips and bronze beaters and operated by a 3-speed mixer. A commercially milled cake flour and a fancy soft clear flour were used in the basic cake-baking formula in which the quantity of soda and cream of tartar had been reduced 16.6 percent to allow for the high altitude (3,780 ft.). Specific gravity determinations were made on the flour and on the batter during the mixing period. Baking tests were made after 1-, 5-, and 10-min. mixing periods.

A smoother batter was obtained with both kinds of flour when the 10-qt. bowl and wire whip were used. The lightest batter with the clear flour resulted from the use of the 3-qt. bowl and wire whip. The results would indicate that beaters and whips are not interchangeable, particularly in the 3-qt. bowl, and that the bowl size and beater specified in the standard cake-baking method must be adhered to for standard results.

The sugar and shortening tolerance of soft wheat flours for cake making, L. COOLEY and J. R. DAVIES (*Cereal Chem.*, 13 (1936), No. 5, pp. 609-613, figs. 5).—Following the standard cake-baking method, the authors tested two commercially milled flours—a fancy clear and a short patent—and one experimentally milled flour. The sugar content was increased 10, 20, and 30 percent and the shortening content 25 and 50 percent. In the baking tests the experimentally milled flour showed a sugar tolerance less than 10 percent, the fancy clear flour less than 20 percent, and the short patent flour less than 30 percent increase. The experimentally milled flour showed a shortening tolerance less than 25 percent and the fancy clear and short patent flours less than 50 percent increase. "With each increase in sugar the cakes became heavier, the grain coarser, the texture harsher, the crusts browner and flatter, until they finally fell. With each increase in shortening the cakes became heavier and greasier, the grain closer, and the crusts flatter."

Sugar tolerance in the A. A. C. C. basic formula for testing cake flours, W. E. STOKES and L. K. TRACK (*Cereal Chem.*, 13 (1936), No. 5, pp. 621-627).—Series of cakes were made in which dry sugar and sirup were added to the basic formula in 10-, 20-, and 50-percent increments. The flour used had a tolerance to dry sugar equal to a 20- to 30-percent increase and to sugar in sirup form equal to a 10-percent increase over the basic amounts.

The control cakes made with all dry sugar and all sirup were identical in volume, with the latter of slightly better texture, more even grain, and clearer color. When the sugar was added in sirup form, the volume, texture, and grain ratings were decreased and the dense structure of the cake prevented collapse, although the tolerance point was not extended. When the sugar and liquid contents were each increased 10 percent, the volume of the cake was less than that of the all-sirup cake containing a 10-percent increment of sirup. When dry sugar was used and the water content was increased at the rate of 10 percent of the sugar increments, the cake did not collapse until the 40-percent sugar increment had been reached. When the sugar was dissolved in the milk solution of the formula the product was similar to the all-dry sugar cake, but with increased amounts of the sugar-milk sirup the volume became larger, the grain less even, and the tendency to collapse increased. When the amount of leavening agent was increased 5 percent with each 10-percent increment of sugar or sirup, the results indicated that the limits of

sugar tolerance may be extended by adding the sugar in the form of sirup of the same density as the original sugar-liquid combination in the mix when the leavening agent is also increased. It is recommended that for the purpose of determining the sugar tolerance of a flour the dry sugar should be used without any variable as to the method of adding the increments to the amount of sugar in the basic formula.

The technique of photography for permanent records of baking studies, L. COOLEY and J. R. DAVIES (*Cereal Chem.*, 13 (1936), No. 5, pp. 613-620, figs. 13).—The authors demonstrate the use of photographs, as prepared by Harrel (E. S. R., 64, p. 281) as one of the best available means of permanently recording the results of baking research.

Chemical composition and fermentation studies of citron, C. R. FELLERS and E. G. SMITH (*Jour. Agr. Res. [U. S.]*, 53 (1936), No. 11, pp. 859-867, figs. 3).—In this investigation at the Massachusetts Experiment Station fresh unripe citron (*Citrus medica*) imported from Puerto Rico was subjected to fermentation and curing processes, and the fresh and cured products were analyzed for proximate and mineral composition and for vitamins A and C.

The fermentation process was similar to the commercial process followed with the Corsican citron, and the organisms isolated from the fermenting brine were the same, *Saccharomyces citri medicae* and *Bacillus citri medicae*. The fermented citron was found to soften and lose its characteristic flavor unless the brine was raised to a concentration of 10 or 12 percent after the fermentation was complete, or was treated with SO_2 or Na_2SO_3 in sufficient concentration to give from 200 to 500 p. p. m. of SO_2 . The peel was preserved by the usual process of desalting the citron and building up, by the addition of hot sirup, a sugar concentration from 15 to 20 percent at the beginning to about 75 percent. A combination of glucose sirup with sucrose was found to give much better results than sucrose alone. The mixture found most satisfactory contained 65 percent of sucrose and 35 percent of glucose and the preserved citron from 70 to 74 percent total sugars, with a final moisture content of between 17 and 19.5 percent. The data on the composition of the experimentally preserved fruit are as follows: Moisture 18.81 percent, ash 0.48, protein (N \times 6.25) 0.13, ether extract 0.33, crude fiber 1.37, total carbohydrate except fiber 78.85, calcium oxide 0.06, phosphorus pentoxide 0.038, and potassium oxide 0.021 percent and ferrous oxide 4.1 and cupric oxide 1.7 p. p. m.

The fresh green citron proved to be rich in vitamin C, 6 international units per gram, but there was little retention of the vitamin in the brined, fermented citron. The vitamin A content of the fresh green citron was estimated as from 0.8 to 1 international unit per gram on the basis of 1 Sherman unit being equivalent to 1.4 international units. The preserved citron contained slightly less vitamin A.

Nutrition in health and disease, R. MCCABRISON (*Brit. Med. Jour.* No. 3951 (1936), pp. 611-615).—In this paper, read before the Section of Nutrition of the British Medical Association, the author surveys the contacts established between nutrition and the other sections into which the clinical and scientific work of the association is divided.

Basal metabolism of girls, F. B. TALBOT (*Amer. Jour. Diseases Children*, 52 (1936), No. 1, pp. 1-15, fig. 1).—The author discusses the various physiological factors which influence heat production and points out that the lack of understanding of these factors may explain some of the errors of clinicians in the past. He attempts to find where possible errors may occur, coordinate the findings, and select the standard that will be consistent with clinical experience.

He accepts the theory, agreeing with physiological and clinical fact, that heat production is primarily dependent upon the amount of active protoplasmic tissue in the body.

The standard procedure should be based on two basal periods with values checking to within 4 percent, the kymographic curve should show a regular swing of the recorder and a gradual upward incline, and the pulse rate should be low. A statistical study of the collected data on 2,200 children shows that the level of heat production differs in different parts of the country and, therefore, the standard should be corrected for each community. The increase in weight does not correspond so closely with the increase in metabolism as does the increase in height. The menstrual cycle causes a variation shown by a premenstrual rise and a maximum fall of 5 percent during menstruation. The amount of protein ingested may be an important factor in affecting the basal metabolism level.

Comparing the new standard with other standards based on height, weight, and age, the author favors the assumption that weight standards more closely represent the clinical status. Select groups of children with cretinism and hyperthyroidism when tested demonstrated that the percentage deviation from the standard for weight was more consistent with the clinical status than was the percentage deviation from the standard for height. The conclusion is that the weight standard gives the most accurate clinical pictures, because the results obtained by it confirm clinical experience, the standard is statistically as accurate as other standards for older girls and is more accurate for young children, and it is also more accurate for pathological conditions and more consistent with the findings in cretinism and hyperthyroidism. The author urges clinicians to obtain actual basal data, know what a standard means and how it is constructed, and when they interpret findings to remember that there are normal physiological reactions which are capable of affecting the metabolism.

Menus and recipes for lunches at school, R. S. CARPENTER, H. N. HANN, and F. W. YRATMAN (*U. S. Dept. Agr., Misc. Pub. 246 (1936), pp. II-25*).—This publication contains information regarding the kind and amount of food to serve for the noon meal in nursery and day schools. Sample menus, large quantity recipes, and purchasing suggestions are given.

The relation of diet to the occurrence of gastric lesions in the rat, E. L. HOWES and P. J. VIVIER (*Amer. Jour. Path., 12 (1936), No. 5, pp. 689-700, pls. 2*).—Groups of young and adult rats, hooded and albino strains, were placed on a modified Pappenheimer-Larimore lesion-producing diet of flour and salt mixture (*E. S. R., 53, p. 165*). After 42 days 90 percent of the young rats developed stomach lesions, accompanied by anorexia, xerophthalmia, and failure to gain weight, while the adult rats remained free from these symptoms for 61 days. When the adult rats were starved every other day, 70 percent developed stomach lesions within 49 days. The young rats showed improved growth when adequate amounts of vitamins A and D were supplied, but 50 percent of them and 60 percent of the adult rats developed lesions. Carotene and butter supplements also failed to protect them. The addition to the diet of 5 percent whole yeast alone or in combination with 5 percent of cod-liver oil or 20 percent of casein protected the young rats, and an increased quantity of yeast the adult rats. When the amount of flour and salt mixture was restricted, 5 percent of whole yeast granted less protection than when a liberal amount of the diet was allowed or when other food factors were supplied. The addition of 10 percent of dried feces to the diet prevented the lesions. The ulcerations occurred in hypertrophied squamous epithelium in the rumen and glandular portions of the stomach. "There is no similarity between these lesions and peptic ulcer in man."

A technic for determining the rate of absorption of fats, M. H. IRWIN, H. STEENBOCK, and V. M. TEMPLIN (*Jour. Nutr.*, 12 (1936), No. 1, pp. 85-101, fig. 1).—In this contribution from the Wisconsin Experiment Station the authors describe a method of determining the comparative rate of absorption of fat from the alimentary tract of the rat. Adult male rats following a 48-hr. fast were lightly anesthetized, and by means of a urethral catheter 1.5 cc of melted fat was delivered directly into the stomach. In a similar manner 1.5 cc of fat was delivered into a beaker and weighed. When the desired time had elapsed, the animals were decapitated, and the stomach, small intestine, and cecum were immediately ligatured, removed, and separated, the intestine being cut into two parts and each section filled with distilled water. After 10 min. the contents were emptied into beakers. The sections were then filled with petroleum ether for 10 min. and after emptying, the organs were cut open and washed thoroughly. The contents were extracted in petroleum ether and the washings transferred to separatory funnels and extracted with petroleum ether. The four extracts were combined and anhydrous sodium sulfate added. The extract was then filtered and the sulfate washed thoroughly. After standing overnight the beakers were placed in a vacuum oven at from 92° to 95° C. for ½ hr. under a pressure of 610 mm of mercury and 2½ hr. under a pressure of 85 mm of mercury, cooled, and weighed.

To test the accuracy of the technic, groups of rats fed 1.5 cc of melted fat were immediately killed and between 95 and 100 percent of the ingested fat recovered. When a group of 7 rats was fasted 48 hr., killed, and the fat extracted by the above method, the mean weight of fat obtained was 0.0222 g, and this figure was applied as a correction to all calculations. Other tests demonstrated that age within the limits of the test, 4-7 mo., did not significantly influence the rate of fat absorption, and that the difference between the sexes was not statistically significant. Pregnancy was not a factor.

The chylomicron and the hemolipokrit methods for determining blood fat did not give comparable results, and neither method was found to be satisfactory for quantitative use. No definite correlations were found between the grams of fat absorbed and the body weight, body surface, or length of the intestines.

The comparative rate of absorption of different fats, H. STEENBOCK, M. H. IRWIN, and J. WEBER (*Jour. Nutr.*, 12 (1936), No. 1, pp. 103-111).—Employing the technic outlined above, various fats were fed to groups of 10 or more rats and the percentage of fat absorbed at 2, 4, 6, 8, and 12 hr. was determined for 342 individual experiments.

Partially hydrogenated vegetable oils were absorbed as readily as lard or corn oil. Butter, halibut liver, and cod-liver oils were absorbed uniformly at a more rapid rate than lard, corn oil, or partially hydrogenated fats.

When 1.5 cc of fat was fed, the 4-hr. absorption period was found to be the most suitable one for comparing the rate of absorption. Under these conditions fats were absorbed in the following descending order of percentage: Linseed oil, olive oil, whale oil, soybean oil, peanut oil, rancid lard, cottonseed oil, cacao butter, coconut oil, palm oil, and oleo stock.

The effect of coffee and decaffeinated coffee on oxygen consumption, pulse rate, and blood pressure, K. HOAST, R. J. WILLSON, and R. G. SMITH (*Jour. Pharmacol. and Expt. Ther.*, 58 (1936), No. 3, pp. 294-304, fig. 1).—In this further investigation (E. S. R., 72, p. 873), the subjects were 11 adults of both sexes, aged 23-28 yr., and 3 men aged 50, 57, and 73 yr., respectively. Caffeine was omitted from the diet for at least 2 weeks prior to the experiment and during the experimental period. The Benedict closed circuit helmet ap-

paratus was used in determining the basal oxygen consumption before the administration of coffee and decaffeinated coffee and $\frac{1}{2}$ and $1\frac{1}{2}$ hr. following their administration. Usually the two beverages were used on alternate weekly experimental periods on the same subject. The approximate caffeine content of the coffee was 1.15 percent and of the decaffeinated coffee 0.012 percent. The beverages were prepared by the dripulator method, 75-78 percent of the caffeine being extracted in the process. The following results were obtained from 26 experiments:

With caffeine-containing coffee the average increase of the percentage changes of oxygen consumption from the basal values was +8.3 for the $\frac{1}{2}$ -hr. tests and +9.27 for the $1\frac{1}{2}$ -hr. tests. With decaffeinated coffee the average values were +1.1 and -0.1, respectively. These results show a definite increase in oxygen consumption following the drinking of coffee and little, if any, change following the drinking of decaffeinated coffee. In the majority of cases the pulse rate was decreased and there was a slight rise in systolic and diastolic blood pressure following coffee administration, while negligent and inconstant changes were produced by decaffeinated coffee.

Further studies on copper and iron in metabolism, H. L. KELL and V. E. NELSON (*Jour. Lab. and Clin. Med.*, 21 (1936), No. 11, pp. 1119-1124).—Both male and female rats of the first and second generations on a diet of milk supplemented with iron as $\text{FeCl}_2 \cdot 6\text{H}_2\text{O}$ and copper as $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$ in varying proportions were examined to determine whether or not the sterility in the second generation on the supplemented milk diet is due to degenerative changes in the sex organs as suggested earlier by Waddell (E. S. R., 66, p 90). Metabolism studies were also conducted on the females.

No sterility or degeneration of the testes was observed in the male rats. The testicular weights of both first and second generation animals compared favorably with those on a stock diet. Motile sperm were found, and mating tests were positive. The average weights of paired ovaries from females on the supplemented milk diet were slightly lower than those of the controls on the stock diet, but the organs were normal, as judged by histological tests and by the successful mating of some of the animals with those on the stock diet. The ammonia nitrogen and creatine nitrogen values of the urine of animals on the supplemented milk diet were higher than the values obtained from animals on the stock diet or on milk alone. Creatinine nitrogen was also higher in the urines from animals on milk plus copper and iron than in the urines from animals on milk alone.

Calcium and phosphorus retention in growth, in relation to the form of carbohydrate in the food, M. SPEERS and H. C. SHERMAN (*Jour. Nutr.*, 11 (1936), No. 3, pp. 211-218).—Different forms of carbohydrate were mixed with twice their weight of an otherwise identical adequate control diet (Sherman diet B) and fed to young rats from 28 to 29 days old. At 60 days of age the rats were killed and analyzed for calcium and phosphorus. It was found that calcium retention and also phosphorus retention were essentially alike whether the carbohydrate added to the diet was dextrose, spray-dried corn sirup, dextrin, cornstarch, or sucrose. Within the limits of experimental error calcium utilization was alike on the experimental diets. The ratio of calcium : phosphorus was essentially the same for all animals, and at the end of the experiment the percentages of calcium and phosphorus in the bodies were essentially the same for the animals on the experimental diets as for those of the same age on the control diet.

Rickets in rats.—XV, The effect of low calcium-high phosphorus diets at various levels and ratios upon the production of rickets and tetany, A. T. SHOHL (*Jour. Nutr.*, 11 (1936), No. 3, pp. 275-291, fig. 1).—The author

extended and supplemented previous investigation of high calcium-low phosphorus diets (E. S. R., 68, p. 871) to include the low calcium-high phosphorus diets. During a 21-day period young rats were fed modifications of the Steenbock-Black diet 2965 consisting of 79 percent corn, 20 percent gluten, and 1 percent sodium chloride, with corn meal substituted for ground corn when lower phosphorus values were desired. By the additions of appropriate amounts of calcium and phosphorus, the calcium level was varied from 0.06 to 1 percent and the phosphorus level from 0.12 to 2 percent. The acidities of the diets were varied from +70 and +12 cc 0.1 N acid per 100 g of basal diets to from -365 to +495 cc 0.1 N acid per 100 g of diet. Galvanic electrical reactions to show the presence of tetany were determined weekly by the Shohl and Bing method (E. S. R., 60, p. 493). At the end of the experiment roentgenograms and histological examination of the bones, the latter by S. B. Wolbach, were made, and serum calcium and phosphorus, total nitrogen, and the percentage of ash in fat-free femurs were determined.

The results show that rickets may be present when the serum phosphorus or calcium, or both, are low, and that tetany occurs when calcium is low and phosphorus is high. As the calcium and phosphorus levels in the diet were increased at a given ratio, the serum calcium and phosphorus and the percentage of ash of the fat-free femurs also increased, while the rickets and tetany diminished. The nitrogen values remained fairly constant. In the absence of vitamin D it was found that rickets may be produced with low calcium-low phosphorus diets, as well as with low calcium-high phosphorus and high calcium-low phosphorus diets.

Vitamin studies on apples, I. A. MANVILLE, A. C. McMINIS, and F. G. CHUINAARD (*Food Res.*, 1 (1936), No. 2, pp. 121-140, fig. 1).—Following the same procedure and employing the method of determining the vitamin A potency on the basis of the minimal protective dose as discussed in the previous study (E. S. R., 72, p. 880), the authors derive the following values for apples: Vitamin A—Arkansas Black 36 units, Baldwin 15, Delicious 24, Gravenstein 14-17, Jonathan 24, Spitzenberg 36, and Winesap 36 units per ounce; vitamin B complex—the results obtained with Delicious, Gravenstein, and Spitzenberg showed that they cannot be considered good sources; vitamin C—Arkansas Black less than 2.5, Gravenstein 3.75, Baldwin 2.5-3, Delicious less than 2.5, Jonathan 1.5-2, Spitzenberg 7, and Winesap 3 units per ounce. Tests with Winesap and Delicious apples demonstrated very little if any loss of vitamin A during prolonged storage. The amount of vitamin C destroyed during prolonged storage appeared to vary with the kind of apple, no change being noted in the Delicious, a slight loss in the Jonathan, and a marked loss in the Baldwin. Peeling the apple did not result in a marked decrease in the vitamin C content. Further data are presented to substantiate the statement that the vitamin A and vitamin C values are associated with gene activity rather than chromosome number.

New developments in nutritional value of apples as the result of research and clinical experience, I. A. MANVILLE (*Better Fruit*, 31 (1936), No. 5, pp. 3-5, 16-18).—In this address, delivered at the annual convention of the International Apple Association in Boston, the author presents a review of his research studies during the past 4 yr. as noted above, and the findings of other investigators to show that the apple possesses great therapeutic advantages. The subject matter is concerned largely with the value of such food materials as the apple in maintaining normal balances in the stomach and intestine, supplementing the acid in the stomach when it is low, acting as a buffer and as a protective colloid in the intestine, and providing rich sources of materials for conjugation purposes so that the injurious effects of toxic

materials may be reduced. "Fruits such as the apple should be considered as being more than food. They are medicinal agents possessing both prophylactic and therapeutic powers."

The interrelationship of vitamin A and glucuronic acid in mucine metabolism, I. A. MANVILLE (*Science*, 85 (1937), No. 2193, pp. 44, 45).—The statement is made that by goblet cell counts of comparable areas of entire villi in the gastrointestinal tract a marked reduction has been shown in the number of mucus-secreting elements and an increase in the number of goblet cells in vitamin A deficiency. This exposes the lining of the tract to injuries produced by the solid components of the food or feces, resulting in capillary bleeding. "We believe that the occurrence of occult blood in the feces is the earliest evidence obtainable of a deficiency of vitamin A."

In an attempt to throw light on the mechanism of mucus production, rabbits on a diet of oatmeal and water were depleted of glycuronic acid by the administration three times daily by stomach tube of gradually increasing doses of menthol, which combines with glycuronic acid with excretion of menthol glycuronate in the urine. Animals which survived for from 2 to 4 days showed on autopsy ulcerative and erosive changes bearing close resemblance to those of vitamin A deficiency in the stomach, pylorus, gall bladder, and intestines.

It is suggested that the ulcerative and erosive changes in the gastrointestinal mucosa may be due to the presence in the body of toxins requiring conjugation with glycuronic acid for their detoxification, with consequent lowering in the amount of mucin formation. Vitamin A is considered to be involved in some way in this mechanism. "The fact that it does not seem probable that all the benefits enjoyed by vitamin A-deficient animals when fed whole apple [as indicated above] is due to vitamin A only is further evidence in this connection. More work is being done along this line, and it is hoped that more information will be provided in the near future."

The vitamin B complex, R. A. PETERS (*Brit. Med. Jour.*, No. 3957 (1936), pp. 903-905).—In this communication to the section of nutrition of the British Medical Association at its 1936 meeting, vitamin B₁ (aneurin, torulin), lactoflavin, and vitamin B₂ are recognized as the most completely defined of the factors of the original B complex at the time of writing. Vitamin B₁ is discussed at considerable length as concerns its chemical nature, function, and tests and the effects of mild deficiency. The flavines and vitamin B₂ are treated very briefly, with the suggestion that the significance of lactoflavine is that it is part of the essential yellow oxidation enzyme of Warburg. The fact that it evidently cannot be synthesized by the animal, that it has been proved essential to rats, and is considered to be needed by dogs leads the author to state that "we must keep our eyes open for its application to man, though Dann [*E. S. R.*, 76, p. 136] claims that it has no effect on human pellagra." Vitamin B₂ "seems to be the real antidermatitis factor and, therefore, must form the main constituent of the original vitamin B₂. (Its possible relation to pellagra in man must still be considered to be not properly defined)."

Other suggestions concerning the relation of the B vitamins to human pellagra are cited, as well as the relation of one or more of these vitamins to acrodermia or pink disease, to heart block, and to cataract.

An extensive list of literature references is appended.

The antineuritic vitamin (B₁) content of some seed oils [trans. title], V. ZAGAMI (*Quad. Nutr.*, 1 (1934), No. 4, pp. 284-294).—Following the technic proposed by G. Amantea of determining the "beriberi quotient Q_b" in pigeons, and considering the antineuritic value of corn oil as 1, the following vitamin B₁ values were obtained: Almond 0, walnut 1.12, pippin 1.56, peanut 2.75, pistachio 4.06, sesame 4.06, pine 9.25, and sunflower seed oil 26.

Vitamin studies (*Oklahoma Sta. [Blen.] Rpt. 1935-36, pp. 75, 76*).—This progress report of studies by R. Reder on vitamins B and G includes a discussion of survival periods, food consumption, and weight losses of rats on different vitamin B-free diets and of the water intake and urine analyses of rats on diets deprived of vitamin B or vitamin G.

The vitamin B₁ and B₂ (G) content of South Dakota lamb (muscle, heart, kidney, liver, tongue, brain, and pancreas), E. PIERSON (*South Dakota Sta. Rpt. 1936, p. 29*).—Further progress is reported on the investigation noted previously (E. S. R., 75, p. 728).

The water-soluble B-vitamins.—VI, Flavin and vitamin B₂ in cereals, A. M. COPPING (*Biochem. Jour., 30 (1936), No. 5, pp. 849-856*).—In continuation of the study noted previously (E. S. R., 76, p. 426), the author investigated the dietary factors present in 80-percent alcoholic extracts of whole wheat and corn and milled cereal products prepared according to the Bourquin-Sherman method (E. S. R., 66, p. 410), and the relative amounts of the two components of vitamin B₂ present in the cereals.

An initial experiment demonstrated that the alcoholic extract of whole wheat contained a fair amount of vitamin B₂ but was deficient in flavine, since the animals receiving the whole wheat extract in the experimental diets composed of casein 15 percent, salt mixture 4, hardened cottonseed oil 8, lard 2, cornstarch 49 and 12, respectively, and cornstarch plus cereal extract 19 and 56 percent, respectively, after from 3 to 5 weeks, showed a severe degree of the "b" type of generalized skin affection, and the addition of vitamin B₂ prepared according to the method of Chick et al. did not alleviate the symptoms or restore growth until flavine was given. Twelve γ of heparflavine daily for 4 weeks were sufficient to heal the skin lesions and restore growth. Further experiments with young rats placed at weaning time on diets containing extracts of whole wheat and corn and milled cereal products demonstrated that the wheat extract at higher levels of intake, supplemented by flavine, appeared to be better in growth-promoting effect than the corn extract. The extracts from milled cereal products when supplemented with flavine produced a much lower growth response in proportion to the intake than the extracts from whole cereals. It must, therefore, be concluded that a considerable portion of the vitamin B₂ is lost in milling and is, therefore, situated in the germ and integuments.

Diets containing 50 percent whole wheat or corn were fed to young rats and the results, judged by weight increases, indicated the presence of the whole vitamin B₂ complex in whole wheat but a lack of the flavine component in whole corn. The results of tests with white flour showed that the alcoholic extract contained only from one-third to one-fourth of the vitamin B₂ present in the flour. Another experiment, using diets containing 30 percent of whole wheat or corn, showed that the corn extract contained less vitamin B₂ than an equivalent amount of whole corn, and that less than one-third of the vitamin B₂ in whole wheat was removed by two extractions with cold 80-percent alcohol. Some of the experiments with corn and corn extracts suggest the possibility that a deleterious substance is present and may be extracted by cold 80-percent alcohol. The author states that more reliable results would be obtained by giving the test material as separate doses rather than using the Bourquin-Sherman type of diet because the variation in intake of food with the appetite of the experimental animals also causes variations in the intake of certain essential dietary factors and makes results more difficult of interpretation.

Electrocardiographic changes in rats deficient in vitamin B₁, P. M. ZOLL and S. WESS (*Soc. Expt. Biol. and Med. Proc., 35 (1936), No. 2, pp. 259-262, fig. 1*).—Rats on a diet sufficiently deficient in vitamin B₁ to cause marked loss in

weight, neurological manifestations, and bradycardia were used to obtain electrocardiograms before and after the subcutaneous administration of from 5 γ to 25 γ of crystalline vitamin B₁ (Merck).

During a period of 3 weeks on the markedly deficient diet the heart rate of the 9 rats under experiment gradually fell from a range of 504 to 666 (with an average of 581) beats per minute to from 354 to 134 (with an average of 286 beats per minute). In 5 of the rats the electrocardiograms showed T-wave changes of high origin but not uniform. In certain cases increases and in others decreases were observed. Both the bradycardia and the changes in the electrocardiographic complexes were abolished following the administration of crystalline vitamin B₁ when the heart rate had not fallen below 300. This was equally true if the animals were kept in a fasting state during treatment, thus indicating that the cardiac changes are directly related to vitamin B₁ deficiency rather than to malnutrition, although it is thought that the latter may play a secondary role.

The results reported are pointed out as in harmony with the electrocardiographic changes observed in human deficiency states, such as pellagra, polyneuritis, and beriberi. The essential difference is thought to be the presence of tachycardia in man rather than bradycardia in deficiency states attributed to vitamin B.

Avitaminosis.—XVIII, Peripheral nerves in vitamin B₁ deficiency as observed by polarized light, J. LEE and B. SURE (*Soc. Expt. Biol. and Med. Proc.*, 35 (1937), No. 4, pp. 583, 584).—In this continuation of the previously noted series of papers from the Arkansas Experiment Station (E. S. R., 75, p. 426), a preliminary report is given of the application to the study of nerve degeneration in vitamin B₁ deficiency of the polarized light technic of Sutton, Setterfield, and Krauss (E. S. R., 73, p. 134).

Particular attention was paid to checking the dependability of the formalin fixation previous to the use of the polarized light. No differences could be observed between the results obtained with nerves fixed in 95 percent alcohol in liquid air and dehydrated in vacuo at -32° C. and those fixed in 10 percent formalin. The preparations studied included small pieces of spinal cord, trigeminal, sciatic, and optic nerves from rats on diets deficient only in vitamin B₁ and with varying degrees of polyneuritis and others on diets deficient in the vitamin B complex. The most regular and marked myelin degeneration was found in the sciatic and trigeminal nerves. A slight degeneration of the spinal cord was noted in 50 percent of the vitamin-deficient animals, but no changes could be observed in the optic nerves in any of the animals. It is noted that the extent of loss of weight in the experimental animals had no direct relationship to the severity of nerve degeneration, and that the nerve degeneration was observed in animals that did not develop paralysis on the vitamin B complex-deficient diet.

Attempts at vitamin C therapy in experimental poliomyelitis, C. W. JUNGBLUT (*Jour. Bact.*, 31 (1936), No. 1, pp. 34, 35).—Previous work having shown that exceedingly small amounts of vitamin C are capable of inactivating the virus of poliomyelitis in vitro, the study was extended to in vivo experiments on monkeys.

Four groups of monkeys were infected with a uniform dose of 0.1 cc of a 10-percent virus suspension intracerebrally. Three of the groups were given varied doses of vitamin C daily by subcutaneous injection, beginning with the day of infection and continuing for a period of 2½ weeks. The 4 animals receiving the smallest dose, 5 mg, survived without showing any symptoms of poliomyelitis. Of 16 animals receiving from 10 to 50 mg, 2 survived without paralysis, 3 developed atypical poliomyelitis after a greatly prolonged incubation period, and

the remainder developed typical paralysis. All of the 9 animals which received the maximal doses (70 to 100 mg) and the 10 controls showed typical poliomyelitis. "Although it is premature to draw any definite conclusions from this preliminary report, there seems to be a strong probability that vitamin C when injected in the proper dose possesses distinct therapeutic power in experimental poliomyelitis."

Vitamin C therapy and prophylaxis in experimental poliomyelitis, C. W. JUNGEBLUT (*Jour. Expt. Med.*, 65 (1937), No. 1, pp. 127-146).—In continuation of the studies noted above, the author presents experimental data obtained from observations on 3 groups of monkeys treated with vitamin C before and after intracerebral infection with 0.1, 0.05, and 0.01 cc, respectively, of a 10-percent virus suspension of poliomyelitis virus. Following injection, daily quantities of vitamin C varying from 5 to 700 mg in group 1, from 5 to 25 mg in group 2, and from 5 to 100 mg in group 3 were injected over a 2-week period. Six of the 34 monkeys in group 1, 1 of the 6 in group 2, and 12 of the 22 in group 3 survived without paralysis. Only 2 of 38 untreated control animals failed to develop paralysis. Large doses of vitamin C were not beneficial, since all of the 10 monkeys receiving from 100 to 700 mg of the vitamin developed paralysis.

The prophylactic administration of from 25 to 500 mg of vitamin C to 26 monkeys for a period of from 1 to 2 weeks before injection of the virus was without any significant effect, and only 2 animals survived without paralysis. Only 1 of the 15 untreated control animals escaped the disease. It is suggested that vitamin C represents one of the deficiency factors in the susceptibility of humans to poliomyelitis.

The role of vitamin C in animals resistant to scurvy: Effects of insulin and adrenaline, K. M. DAOUD and M. A. S. EL AYYADI (*Biochem. Jour.*, 30 (1936), No. 8, pp. 1280-1292, figs. 2).—Male rats were placed on a scurvy-producing diet of Hassan and Basili (*E. S. R.*, 69, p. 904) for periods varying from 3 to 90 days, while the control animals were fed an ordinary mixed diet. The Emmerie modification (*E. S. R.*, 73, p. 583) of the methods of Birch and of Tillmans was applied for the estimation of vitamin C in the organs and in the urine.

The rate of urinary excretion of vitamin C in rats was decreased by a scorbutic diet or the injection of adrenaline and was increased by 24-hr. starvation. The vitamin C content of the adrenals was not altered by the scorbutic diet, 24-hr. starvation, or the injection of insulin or adrenaline. The vitamin C content of the liver was increased by the injection of insulin in the rats on the scorbutic diet but not by adrenaline. The amount of vitamin C excreted in the urine was lowered by adrenaline. The rate of glycogenolysis caused by adrenaline appears to run parallel with the degree of saturation of the body with vitamin C. It is suggested that this degree of saturation is a direct factor in determining the rate of glycogenolysis, or that vitamin C in the reduced form protects the adrenaline from rapid oxidation. The synthesis of vitamin C by rats on a scorbutic diet may be sufficient to insure freedom from scurvy while producing a relatively lower saturation of the body than when a diet containing the vitamin is fed.

The subscurvy state in relation to gastric and duodenal ulcer, H. E. ARCHER and G. GRAHAM (*Lancet [London]*, 1936, II, No. 7, pp. 364-366).—Continuing their observations on ascorbic acid excretion (*E. S. R.*, 76, p. 135), the authors established the degree of saturation of ascorbic acid over a 6-day period in 9 male patients with gastric or duodenal ulcers. The patients were receiving a modification of the Lenhartz diet, which consists of unboiled milk, dried milk food, eggs, biscuits, and butter and contains negligible to small amounts of

vitamin C. In 8 cases 2 oz. of orange juice were added to the diet to bring the vitamin C intake up to approximately 40 mg.

Two healthy men, who served as controls, showed a slight degree of unsaturation of ascorbic acid. Three of the patients were in about the same condition as the control subjects. Of the remaining cases, 5 showed a grave degree of unsaturation, with the percentage excretion from the 400-mg test dose on the third day varying between 44 and 28.5 percent, while more satisfactory results were obtained on the sixth day, when the lowest percentage output was 77.7 percent. One case failed to show any response after a 2,400-mg intake, but on the sixth day excreted 77.7 percent after the ingestion of 400 mg of ascorbic acid.

The evidence that 6 out of 9 patients with gastric and duodenal ulcers are in the "scurvy" state would suggest that the extremely low vitamin C diet prescribed in such conditions should be fortified with additional vitamin C in the form of 2 oz. daily of orange juice, supplying about 36 mg of ascorbic acid, in addition to a dose of 1,000 mg on 3 successive days to insure that the body is saturated.

Cevitamic acid excretion in pneumonias and some other pathological conditions, J. G. M. BULLOWA, I. A. ROTHSTEIN, H. D. RATISH, and E. HARDE (*Soc. Expt. Biol. and Med. Proc.*, 34 (1936), No. 1, pp. 1-7, fig. 1).—In continuation of work noted (E. S. R., 74, p. 137), the urinary vitamin C excretion was followed in additional cases of pneumonia and in other pathological conditions before and after the administration of cevitic acid in doses varying from 100 mg to 1 g, depending upon the age and vitamin excretion of the patient.

"The urinary titration of cevitic acid has confirmed previous work with tissues of experimental animals, namely, the diminution of vitamin C in the course of many intoxications and pathological conditions. These states do not suggest scurvy, and may be designated hypovitaminosis accompanying, or etiologically related to, the pathological conditions with which they occur."

In the pneumonias studied no striking correlation could be drawn between the clinical condition and vitamin C excretion, except that in the greater number of cases a high temperature was accompanied by low excretion and that saturation often accompanied a drop of temperature. This supports the contention of Harris that increased metabolism is associated with increased destruction of the vitamin in the tissue.

Studies upon the mode of action of vitamin D.—I, Investigations upon the phosphorus compounds in muscles, liver, and kidneys as influenced by different levels of vitamin D and phosphorus in the diet, R. NICOLAYSEN (*Biochem. Jour.*, 30 (1936), No. 8, pp. 1329-1337).—Groups of rats were placed on the Steenbock-Black rachitogenic diet (calcium: phosphorus ratio 4:7) and a phosphorus-rich diet (calcium: phosphorus ratio 0:7) with and without vitamin D (50 international units of calciferol daily). One group received the first diet supplemented by 100,000 international units of vitamin D daily over a period of from 10 to 14 days. A group of rachitic rats was given massive doses of vitamin D for varying periods prior to being killed.

In the rachitic rats the values for inorganic phosphorus + phosphagen of muscle and for inorganic phosphorus of liver and kidney were found to be less than for the rats receiving the same diet supplemented by vitamin D. The lipin phosphorus and protein phosphorus in the liver and kidneys, but not in the muscle, of the rachitic rats were similarly reduced. No definite change was observed in the readily or difficultly hydrolyzable esters in muscle or liver or the difficultly hydrolyzable esters in the kidneys. The animals on the phosphorus-rich diet remained normal and gave phosphorus compound values similar to those obtained from animals on the rachitic diet receiving the vitamin

D supplement. Improved calcification resulted when vitamin D was added to the phosphorus-rich diet, but the amount of phosphorus compounds in muscle, liver, and kidneys was unchanged. The administration to the rachitic rats of massive doses of vitamin D for short periods increased the inorganic phosphorus content to the normal level in muscle, liver, and kidneys, and when given for 2 weeks resulted only in an increase of inorganic phosphorus in the kidneys up to double the normal content. "There appears to be no evidence to support the view that vitamin D acts by maintaining a balance between the different forms of phosphorus in the organism."

Relationship shown between capillary resistance and dental caries (*Utah Sta. Bul. 276 (1936), pp. 70, 71*).—In this progress report a summary is given of studies by A. P. Brown on the capillary fragility, as determined by both Dall-dorf and Göthlin technics, of groups of rural school children in the spring and fall and of college women students.

TEXTILES AND CLOTHING

Wool shrinkage (*Wyoming Sta. Rpt. 1936, p. 16*).—Comparisons of large and small samples of wool for shrinkage are briefly noted.

The influence of various kinds of wool on some of the physical properties of flannel, E. PIERSON (*South Dakota Sta. Rpt. 1936, pp. 28, 29*).—In this progress report (E. S. R., 75, p. 734), the relative order for diameter and length of fibers is given for wool from the five breeds of sheep studied—Hampshire, Rambouillet, Shropshire, Southdown, and Tailless, and a few findings are reported as to the effect of dry cleaning on flannel woven from these wools.

Usage of household textiles by farm families, M. E. FRAYSER (*South Carolina Sta. Rpt. 1936, pp. 16-18*).—A summary is given of a survey of the quantities, kinds, and costs of textile materials used for household purposes by 297 white and 294 negro families in eight counties of the State.

HOME MANAGEMENT AND EQUIPMENT

Homemakers contribute to family income (*Oklahoma Sta. [Blen.] Rpt. 1935-36, pp. 164-169*).—A brief summary by G. Fernandes, L. Conner, and M. F. McCollum is given of the analysis of records of the contributions to family income of the homemakers on 163 wheat, cotton, and diversified farms in the State for 1 yr. during the period 1930-34. The summary includes tabulated data on the enterprises engaged in by these homemakers classified by type of enterprise and type of farm, and on the range in money value of these contributions.

A study of selected types of domestic gas stoves, A. E. BARAGAR (*Nebraska Sta. Res. Bul. 86 (1936), pp. 74, figs. 33*).—Seven domestic gas stoves, representing several types of surface burners, burner assemblies, and oven construction, were operated on natural gas of an average heat content of 1,009 B. t. u. per cubic foot, average sp. gr. 0.72, and a normal pressure of 7 in. of water. Six types of surface burners were tested, including the star, cast iron round, die-cast round, Y-, daisy, and continuous or ribbon flame types. These are described and illustrated by photographs, with types of utensils used.

In the surface burner performance tests, the technics for all of which are described, the thermal efficiency was found to depend upon the size and kind of utensil, the construction of the burner, and the type of stove top and grate construction, and to be independent of the quantity of water used, the length of the injector tube, and the gas rate if other factors were kept unchanged. Efficiencies determined by long-time tests in which water was actually boiled were found to be comparable with the average efficiencies for short-time tests

in which the water was heated from an initial temperature of 75° F. to a final temperature of 200°. The time of heating was found to be a function of the gas rate and the efficiency of the burner. However, the gas rate should not be so high as to produce carbon monoxide. The distribution of heat from the burner, as determined by the scorch-pattern method, was found to be a function of the utensil as well as the shape of the burner. Automatic lighters were not uniformly satisfactory or dependable. Boilover tests with either soap or starch solution revealed features of construction of burners and lighters that might otherwise have been missed, such as differences in ease of cleaning burner and cooking top.

From the technical data obtained concerning the performance of the surface burners of the types studied, it is thought that the performance of similar types of burners can be predicted. The heat distribution tests, automatic lighter tests, and boilover tests can be made by anyone. "If these tests are performed and then the efficiency judged on the basis of known data, a fairly comprehensive idea of what a particular burner will do may be obtained."

The oven tests included calibration of thermostat, determination of oven heat capacity, rate of cooling from an initial temperature of 550°, empty oven heat loss, surface temperature and internal heat distribution, open door heat loss, and analysis of the flue gas. The data obtained in these tests showed that it is impossible to predict the performance of an oven in terms of known factors from other ovens. The assumption that actual oven temperatures will agree with the dial setting was invalid at the 400° mark for four of the seven ovens tested. After adjustment of the thermostat so that the dial setting of 400° agreed with the actual oven temperature, temperatures as low as 300° were obtainable with only two of the ovens. Whenever low temperatures could not be obtained, the fault was usually in the burner design rather than in the thermostat. Changes in the burner design of two of the ovens made it possible to produce the low temperature readings. All of the ovens met the requirement of the American Gas Association for oven heating capacity. The heat loss data showed that, although all of the ovens were insulated, much heat was lost, chiefly by losses through the flue and through poorly fitting doors. The surface temperatures were low and the heat distributions within the ovens quite uniform.

Actual cooking tests, both on surface burners and in the ovens, to determine the amount of heat required and variations in the finished products gave results which in general confirmed the technical tests.

Additional information on the laboratory in which the work was done and its equipment, the technic for meter calibration, the construction and operation of a test box for testing surface burners, and data on the effect of temperature on gas rate for type A burners are given in a series of appendixes.

Kerosene cook stoves, M. M. MONROE and P. S. GREENE (*Maine Sta. Bul.* 384 (1936), pp. 406, 407).—This preliminary report on a study of the economical management of kerosene cook stoves in Maine farm households to secure palatability of the product deals with the objectionable features for top-of-stove cooking of present burner designs.

MISCELLANEOUS

List of publications of the United States Department of Agriculture from January 1931 to December 1935, inclusive, compiled by M. G. HUNT (*U. S. Dept. Agr., Misc. Pub. 252* (1936), pp. II+64).—This supplements the list previously noted (*E. S. R.*, 68, p. 874).

Annual Report [of Florida Station], 1936, W. NEWELL ET AL. (*Florida Sta. Rpt.* 1936, pp. 161+IX, figs. 12).—The experimental work not previously

referred to is for the most part abstracted elsewhere in this issue. Meteorological observations in the Everglades (pp. 115-117) and at the North Florida Substation at Quincy (p. 142) are also included.

Sixteenth Annual Report [of the Georgia Coastal Plain Station], 1936, S. H. STARR (*Georgia Coastal Plain Sta. Bul.* 26 (1936), pp. 106, figs. 10).—The experimental work not previously referred to is for the most part noted elsewhere in this issue. Meteorological data are also included.

Report of progress [of Maine Station] for year ending June 30, 1936, [F. GRIFFEE ET AL.] (*Maine Sta. Bul.* 384 (1936), pp. 389-443, figs. 6).—This bulletin contains data noted for the most part elsewhere in this issue or previously, together with meteorological investigations.

Science serving agriculture: Report of Oklahoma A. & M. College Agricultural Experiment Station, 1934-1936, C. P. BLACKWELL ET AL. (*Oklahoma Sta. [Buen.] Rpt.* 1935-36, pp. 191, figs. 24).—The experimental work not previously referred to is for the most part noted elsewhere in this issue. Meteorological observations at Stillwater are also included.

Forty-ninth Annual Report of the Pennsylvania Agricultural Experiment Station, [1936], [R. L. WATTS ET AL.] (*Pennsylvania Sta. Bul.* 336 (1936), pp. 46, figs. 7).—The experimental work not previously referred to is for the most part noted elsewhere in this issue. Meteorological data (pp. 43-45) are also included, and data regarding the following: Influence of Electrolytes Added to Growth Medium on Electrophoretic Potential of *Escherichia coli*, by G. W. Pearce, M. W. Lisse, and R. P. Tittsler (pp. 14, 15); The Effect of Electrolytes Present in the Growth Media Upon the Electrophoretic Mobility of *Escherichia coli*, by J. T. Pedlow and M. W. Lisse (p. 15); The Effect of Certain X-Rays on the Electrophoretic Mobility of *Escherichia coli*, by M. E. Smith, M. W. Lisse, and W. P. Davey (p. 15); The Marketing of Milk, by F. F. Lininger and T. K. Cowden (pp. 16, 17); Rural Tax Delinquency in Pennsylvania, 1928-1932, by P. I. Wrigley (p. 17); and Produce Marketing in Reading and Wilkes-Barre, Pennsylvania, by R. B. Donaldson and J. Gauss (p. 17).

Report of Puerto Rico Experiment Station, 1935 [trans. title], [A. LEE] (*Puerto Rico Sta. Rpt.* 1935, *Span. ed.*, pp. [2]+36, figs. 15).—A Spanish edition of this report (E. S. R., 75, p. 893).

Forty-ninth Annual Report of the South Carolina Experiment Station, [1936], H. P. COOPER ET AL. (*South Carolina Sta. Rpt.* 1936, pp. 144, figs. 30).—The experimental work not previously referred to is for the most part noted elsewhere in this issue.

Annual Report of the South Dakota Agricultural Experiment Station, [1936], J. W. WILSON ET AL. (*South Dakota Sta. Rpt.* 1936, pp. 50).—The experimental work not previously referred to is for the most part noted elsewhere in this issue.

How science aids Utah agriculture: Biennial Report of the [Utah Station, 1935-36], L. NELSON (*Utah Sta. Bul.* 276 (1936), pp. 84, figs. 37).—The experimental work reported is for the most part noted elsewhere in this issue.

Forty-sixth Annual Report of [Wyoming Station, 1936], J. A. HILL (*Wyoming Sta. Rpt.* 1936, pp. 38).—The experimental work not previously referred to is for the most part noted elsewhere in this issue. Meteorological data are also included.

Progress report of the State experiment farms, W. L. QUAYLE (*Wyoming Sta. Bul.* 219 (1937), pp. 47, figs. 7).—The experimental work not previously abstracted is for the most part noted elsewhere in this issue.

NOTES

Arizona University and Station.—Dr. P. S. Burgess has resigned as president to return to his former position as dean of the College of Agriculture and director of the station. He will be succeeded, probably in September, by President Alfred Atkinson of the Montana College.

California University and Station.—Knowles A. Ryerson, in charge of citrus, avocado, and other subtropical fruit investigations of the U. S. D. A. Bureau of Plant Industry, has been appointed director of the branch of the College of Agriculture at Davis, vice Dr. W. L. Howard who will continue as professor of pomology and pomologist.

Indiana Station.—The board of trustees has approved the preparation of plans for a \$175,000 addition to the horticultural building, and an agricultural chemistry building to cost \$145,000. A new barn has also been approved for the dairy farm. Dr. J. L. Roberts has been appointed soil bacteriologist, effective July 1.

Kentucky Station.—The resignations are noted of Dr. W. T. Forsee as assistant chemist, D. E. Bayless as assistant in farm management, and L. V. Amburgey as microscopist in feed control. Ruth McDonald has been appointed technician in the department of animal pathology.

Mississippi College and Station.—Charles T. Ames, assistant director in charge of the Holly Springs Substation since 1906, died April 18 at the age of 68 years. A native of Mississippi, he was graduated from the college in 1890 and associated for about 5 years with its horticultural work. His service at Holly Springs began soon after the establishment of the station, and he was personally responsible for much of its subsequent upbuilding and development.

North Dakota Station.—Dorothy G. Berrigan, assistant in home economics research, resigned April 1. Harold Mattson has been appointed assistant horticulturist, effective May 1, and will be engaged in breeding and other investigations relating to potatoes.

Ohio State University.—President George W. Rightmire has been elected head of the recently established Research Foundation and Hurlbut S. Jacoby, university director of industrial research, as secretary and director. The foundation has a membership of 55, among them the director of the Ohio Station and representatives of the university faculty and alumni and of national industries.

Pennsylvania College and Station.—A new greenhouse, 30 by 150 ft., is to be built for research in horticulture. The greenhouse will be divided into four sections, the two larger ones for research with potatoes and roses and the two smaller ones for vegetable crop investigation.

Robert V. Boucher has succeeded Dr. J. E. Hunter, resigned, in the department of agricultural and biological chemistry.

Clemson College.—A new agricultural building has been completed at a cost of approximately \$400,000, and has been named Long Agricultural Hall in honor of the late Dr. W. W. Long, for many years director of extension. It houses most of the school of agriculture, experiment station, and extension activities, providing office, classroom, and laboratory facilities which have been much needed.

Dedicatory exercises were held May 12, with Dr. Chester C. Davis of the Board of Governors, Federal Reserve System, as the principal speaker and his subject Education and Democracy. The honorary degree of D. Sc. was conferred upon Dr. Davis and 41 others, including from the U. S. Department of Agriculture, Assistant Secretary Harry L. Brown; Dr. J. T. Jardine, Director of Research and Chief of the Office of Experiment Stations; C. A. Cobb and Ivy W. Duggan, Agricultural Adjustment Administration; Dr. R. W. Webb, Bureau of Agricultural Economics; Dr. Henry D. Barker, H. W. Barre, Dr. W. W. Garner, and Dr. W. D. Moore, Bureau of Plant Industry; Dr. Thomas S. Buie and Tandy R. Reid, Resettlement Administration; and Dr. H. H. Bennett and M. L. Nichols, Soil Conservation Service; from the U. S. Farm Credit Administration, Dr. A. F. Lever; from the Tennessee Valley Authority, Dr. J. H. A. Morgan; experiment station directors M. J. Funchess of Alabama, D. T. Gray of Arkansas, Wilmon Newell of Florida, H. P. Stuckey of Georgia, T. P. Couper of Kentucky, R. Y. Winters of North Carolina, and H. H. Zimmerley of Virginia (Truck); extension directors I. O. Schaub of North Carolina, C. E. Brehm of Tennessee, and J. R. Hutcheson of Virginia; Dr. E. W. Garriss and H. H. Hume of the University of Florida; Dean Paul W. Chapman and J. A. Evans of the Georgia College; Dr. J. S. McHargue of the Kentucky University and Station; Dr. G. W. Keitt of the University of Wisconsin; Dr. R. F. Poole of the North Carolina Station; Dr. W. H. MacIntire and L. R. Neel of the Tennessee Station; T. B. Hutcheson of the Virginia Station; Dr. R. E. Remington of the Medical College of South Carolina; Dr. Wilson Gee of the University of Virginia; George E. Freeman, State Supervisor of Vocational Agriculture of Tennessee; Dr. Clarence Poe, Editor of *The Progressive Farmer* and *Southern Ruralist*; and Dr. D. R. Coker and George Wilds, Jr., of Coker's Pedigreed Seed Company.

U. S. Department of Agriculture.—Under a memorandum of April 9, 1937, an Advisory Committee on Research has been set up by Secretary Henry A. Wallace, consisting of F. D. Richey, H. G. Knight, J. R. Mohler, and L. A. Strong, chiefs, respectively, of the Bureau of Plant Industry, Bureau of Chemistry and Soils, Bureau of Animal Industry, and Bureau of Entomology and Plant Quarantine, and E. N. Bressman of the Agricultural Adjustment Administration. This committee will advise the Secretary and Director of Research on such specific research problems as may be assigned them from time to time. It will also, upon its own initiative, survey the field of research within the Department with a view to developing uniform research project systems and obtaining an able research personnel.

The appointment by transfer from the Soil Conservation Service of Merrill Bernard, hydraulic engineer, to succeed M. W. Hayes, deceased, as chief of the River and Flood Division of the Weather Bureau marks a new departure of the Bureau, namely, the selection of a hydrologist rather than a meteorologist to head one of its important divisions. The severe floods of the last few years have shown the need of hydrologic specialists in the task of developing new flood-forecasting methods, preparing and keeping current systems for the prompt collection of rainfall and river stage data, and determining the requirements for flood forecasts in overflow valleys.

Association of Land-Grant Colleges and Universities.—The fifty-first annual convention of this association will be held in Washington, D. C., from November 14 to 17, 1937. A part of the convention period will be devoted to the observance of the seventy-fifth anniversaries of the Morrill Act and the act establishing the U. S. Department of Agriculture and the fiftieth anniversary of the Hatch Act.

EXPERIMENT STATION RECORD

VOL. 77

AUGUST, 1937

No. 2

PERSONNEL CHANGES IN THE EXPERIMENT STATIONS

During the calendar year 1936 there was a net increase in the total station personnel of about 200, raising the total staff to approximately 4,000. Fully 52 percent of these are reported as full-time workers. About 77 percent of the total number have received advanced degrees.

These findings are based on an analysis of the publication prepared in the Office of Experiment Stations entitled *Workers in Subjects Pertaining to Agriculture in Land-Grant Colleges and Experiment Stations* (E. S. R., 77, p. 128). This publication is intended primarily as a directory, but considerable additional information is derivable from its pages if desired. Some variations in the method of compilation occur from year to year, but of late these have been of little significance for statistical purposes and a number of comparisons and deductions may be attempted with an expectation of at least approximate accuracy.

Using as a basis the last two of these reports, issued in March 1936 and 1937 and covering in a general way conditions up to about February 1 of their respective years, it appears that about 3,200 names are recorded for substantially the same positions in the 2 years; that about 150 names were connected with the same stations but with advancement to higher positions; and that about 600 names were new to the stations from which they were reported. The net increase in station enrollment for the later year was about 200, so that in many cases what has doubtless occurred has been a transfer from one station to another.

Because of divided duties, the total manpower of the stations is much less than the aggregate of individuals. The count shows 52 percent of the employees enrolled as full time, but affords no basis for estimating the proportion given to station work by the 48 percent also engaged in teaching, extension, and/or other nonstation work. Comparison is possible, however, with the findings in a similar survey reported in these columns in 1921 (E. S. R., 44, p. 301). At that time fully 60 percent of the station staff had additional duties, a substantial increase from the 43 percent so reported in 1911. It would therefore

appear that the drift toward part-time workers, regarded as unfortunate in the discussion of 16 years ago, has now ceased. Further analysis shows that the majority of the full-time employees are in the assistant and similar grades, perhaps justifying the conclusion that at least the routine of station research is increasingly being organized on a full-time basis.

A survey of the situation as regards advanced degrees reveals that in 1935 approximately 38 percent of the stations' staff had earned doctors' degrees, while for 40 percent of the entire number the master's degree was their highest. In 1936 these proportions were 40 and 37 percent. While nearly 100 more individuals were reported with only the bachelor's degree in 1936, this increase is probably largely the result of the greater number of assistants made possible by increased funds, and it is reasonable to assume that many of these assistants are already taking graduate work. Much more significant is the increase of over 100 in the number of earned doctorates. The survey in 1921 revealed only 48 percent of the staff with advanced degrees, and in 1911 there were only 32 percent. At that time, it was said, "a relatively small fraction of the degrees were beyond that of the master's; only 8½ percent of the whole force in 1911 and 15 percent of the present force had taken the doctor's degree. This increase in the proportion of workers having second degrees is gratifying as showing a considerably higher academic standard than 10 years ago, but considering the expert nature of the stations' activities, the fact that less than a third of the whole staff then and less than half now have gone beyond the bachelor courses points to a situation which is likely to prove a handicap in original inquiry." Today this situation seems to have been considerably ameliorated.

Further analysis of the material at hand would doubtless disclose additional details of interest, and it would seem that there is an opportunity for more intensive personnel studies which might prove enlightening and of considerable practical value. The points brought out in the present cursory discussion indicate that progress is being made in meeting some of the problems of earlier years. This is cause for congratulation.

RECENT WORK IN AGRICULTURAL SCIENCE

AGRICULTURAL AND BIOLOGICAL CHEMISTRY

Principles of biochemistry, A. P. MATHEWS (*Baltimore: William Wood & Co., 1936, pp. I+512, [pls. 51]*).—In this textbook for medical students the subject matter is divided into six parts: The chemistry and metabolism of the glucides, of the lipids, and of the proteins, the special chemistry of the blood and connective tissues, the catalytic agents of growth and development—vitamins and hormones, and the income of energy. Since this is not intended to be a reference handbook, almost all references to the literature have been omitted.

[**Chemical investigations of the Delaware Station**] (*Delaware Sta. Bul. 205 (1936), p. 23*).—This presents concise summaries of work on enzymatic hydrolysis of starch in pectic extractions from apple pomace and the extraction of phospholipoids from the soybean oil meal, both by A. A. Horvath.

[**Chemical investigations of the Iowa Station**] (*Iowa Sta. Rpt. 1936, pt. 2, pp. 55-58*).—Progress notes are given on certain chemical and physical characteristics of corn as these relate to industrial utilization, by R. M. Hixon; identification of the water-soluble and the acid hydrolyzable carbohydrate constituents of the cornstalk, by W. G. Gaessler and Hixon; the physical properties of dextrose, by J. H. Buchanan; and fermentation products of xylan and utilization of agricultural products in the fermentative production of lactic acid, both by C. H. Werkman.

Preparation of gliadin and zein, L. S. NOLAN and H. B. VICKERY (*Soc. Expt. Biol. and Med. Proc., 35 (1936), No. 3, pp. 449-451*).—The novel feature of these two methods, devised at the Connecticut [New Haven] Experiment Station, consists in the means adopted for securing a precipitation of the respective prolamines in a satisfactory physical condition.

Gliadin was extracted from wheat gluten flour by 70 percent alcohol at 55°-60° C, the solution was filtered clear through a thick paper-pulp mat, and it was concentrated, until the frothing became uncontrollable, under reduced pressure. To effect precipitation, "the clear concentrated alcoholic solution is placed in lots of about 1 l in a large enamelware tub, and water is violently squirted into the tub in such a manner as to cause the greatest possible agitation. Under these conditions, the gliadin separates from solution in the form of a highly aerated froth. This is skimmed off and, when all has been collected, is thoroughly beaten or whipped with a wire cream beater until homogeneous. The froth is then placed in a thin layer (3-5 cm) on pans and is rapidly dried in a current of warm air (70°-80°). After the froth has become somewhat dry on top, any water that has accumulated beneath it is poured off.

"The drying must be rapid in order to avoid a collapse of the froth. When correctly dried the product is a crisp, white, much expanded mass. It is crushed by hand and passed through a mill to reduce it to a light somewhat scaly powder."

Zein was extracted from corn gluten by hot (50°-60°) 80 percent alcohol and filtered in the manner already indicated. "The filtrate is treated in convenient portions with an equal volume of ether, and the precipitated protein is thoroughly stirred with the fluid which is finally poured off. This step removes most of the fat and pigment, and is less troublesome than the extraction with ethylene dichloride advocated by Mason and Palmer [E. S. R., 75, p. 5b2]. Reprecipitation of an alcoholic solution of the protein with ether may be carried out if a product of high purity is sought.

"The precipitated protein is dissolved in a small amount of warm 80 percent alcohol, and should form a perfectly clear although very thick and viscous solution. This is transferred to a separatory funnel with the aid of a little diluted alcohol, and the funnel is set up over the following device: A large sheet of cotton gauze (cheesecloth) is spread on a wire-mesh rack in a sink and on it is placed a shallow round pan (milk pan). Water from a hose which has been fitted with a glass nozzle constricted so as to deliver a rapid flat stream about 2 cm wide is directed into this pan. A very thin continuous stream of the zein solution is then allowed to fall from the separatory funnel upon this stream of water. The zein is partially precipitated at contact, and the process is completed in the violently agitated water in the pan. Most of the protein is washed out of the pan but is retained by the gauze. At the end of the operation it is collected in the gauze, thoroughly washed with water, and is finally allowed to remain in water overnight. It is then filtered on a Buchner funnel, spread in a thin layer on pans, and allowed to dry at room temperature. Before it becomes thoroughly dry, there is a point at which it can be easily rubbed through a fine sieve whereby a uniform product is obtained."

Dough structure and properties. C. H. BAILEY (*Northwest. Miller*, 188 (1936), No. 5, pp. 433, 434).—The author presents, from the Minnesota Experiment Station, a condensed, semipopular discussion of the physics and chemistry of the formation of doughs and of their behavior during fermentation.

Biochemical methods for the study of nitrogen metabolism in plants. F. S. ORCUTT and P. W. WILSON (*Plant Physiol.*, 11 (1936), No. 4, pp. 713-729, figs. 2).—This contribution from the University of Wisconsin suggests a method of preparing plant sap for analysis "which eliminates the uncertainty of extraction and precipitation methods. Hydrolysis of amide nitrogen is accomplished without humin formation by hydrolyzing with 20 percent sodium bisulfite in a steamer for 3 hr. (Humin formation amounts to 12 to 15 percent of the soluble nitrogen in soybeans.) Hydrolysis of nitrogen compounds between proteins and amino acids by an enzyme solution containing proteinase, carboxypolypeptidase, aminopolypeptidase, and dipeptidase [extracted with water from the mycelial mass of cultures of *Aspergillus parasiticus* or of *A. ncentii* after grinding] is also accomplished without humin formation. The error in phosphotungstic acid precipitation and 'other nitrogen' owing to the presence of peptides, etc., is eliminated by the hydrolysis procedure. Determination of alpha amino nitrogen before and after hydrolysis may be used as a more accurate method of determining peptide nitrogen than precipitation methods."

Two nitrogen fractionations of top and root sap of soybeans showing the difference in nitrogen distribution before and after hydrolysis, to illustrate the value of the proposed system of analysis, are given, and the suggested procedure for nitrogen fractionation in plant juice is outlined.

Lipase production by *Penicillium oxalicum* and *Aspergillus flavus*. D. KIRSH (*Jour. Tenn. Acad. Sci.*, 11 (1936), No. 4, pp. 250, 296).—The author very

briefly notes experiments to determine optimal conditions for the production of lipase extractable from cultures from two of the organisms named. It is stated that "lipase precipitated from the *P. oralleum* extract by means of alcohol contained $8\frac{1}{2}$ times more of this enzyme per unit of protease than did a commercial high lipase trypsin. The activity was low when obtained from large cultures; the dry enzyme prepared from small lots of medium showed good activity."

On the mechanism of enzyme action: A study of the decomposition of monoethyl hydrogen peroxide by catalase and of an intermediate enzyme-substrate compound, K. G. STERN (*Jour. Biol. Chem.*, 114 (1936), No. 2, pp. 473-494, figs. 6).—In an investigation of the decomposition of monoethyl hydrogen peroxide by liver catalase, a volumetric procedure was used for the assay of the peroxide. The kinetics and the effect of temperature, of pH, of varying the substrate concentration, and of cyanide on the enzyme reaction were studied. The results are compared with those obtained with hydrogen peroxide as substrate.

"In the course of the enzymatic process there is formed an intermediate compound with a characteristic absorption spectrum. The intermediate is unstable; it breaks down to form free enzyme and reaction products. . . . A preliminary optical study of this compound has revealed that it is not a mere absorption complex; that the rate of formation of the enzyme-substrate compound is great compared with that of the total reaction; that it has a smaller temperature coefficient than the over-all reaction; that it is independent of pH between 4 and 9."

Formation of sulfide by some sulfur bacteria, R. L. STARKEY (*Soc. Expt. Biol. and Med. Proc.*, 35 (1936), No. 1, pp. 120-122).—In an investigation reported from the New Jersey Experiment Stations, "lead acetate paper suspended over the culture solution containing elemental sulfur and inoculated with *Th[iobacillus] thiooxidans* showed slight darkening after growth for 10 days. The test for sulfide became increasingly stronger with longer growth. Cultures of *T. thioparus* growing on a thiosulfate medium produced slight darkening of the lead acetate paper in 4 days and within another week showed deep blackening. The test for sulfide was preceded many hours by the precipitation of sulfur in the medium, a transformation which characterizes growth of this bacterium on thiosulfate.

"There can be no question as to the production of sulfide by both bacteria, but there is no indication that any appreciable quantity persists in the medium. It seems most probable that the sulfide is formed in both cases by reduction of elemental sulfur. The reduction of elemental sulfur to sulfide is effected by compounds containing —SH groups in animal and plant tissues and by glutathione. The occurrence of —SH groups has been established for a great variety of tissues and organisms, including many filamentous fungi and bacteria. In the present studies, cellular material of several organisms, including bacteria, fungi, and actinomycetes, has been found to form sulfide from elemental sulfur. It is concluded that formation of sulfide by the sulfur bacteria is evidence that these organisms also contain substances possessing active —SH groups."

Second report of the Organic Carbon Committee, E. M. CROWTHER (*3. Internatl. Cong. Soil Sci., Oxford, Eng., 1935, Trans., vol. 3, pp. 82, 83*).—This very brief report contains only additions and corrections to the first report, already noted (*E. S. R.*, 76, p. 583).

A nomogram for the relation between the quinhydrone potential and pH at various temperatures, G. KNAYS (Food Res., 1 (1936), No. 3, pp. 297-299, fig. 1).—The chart constructed by the author of this contribution from the

[New York] Cornell Experiment Station is derived from the equation
$$pH = \frac{V + 0.4529 + 0.00002 t}{0.00019832 T}$$
 in which V represents the voltage with respect to the saturated calomel electrode, t the centigrade temperature, and T the absolute temperature.

"By transforming the above relation to the form $T - \frac{V + 0.447438}{0.00019832 pH - 0.00002} = 0$, it reduced to the classical form $f_1 f_2 + f_3 = 0$ representable by a nomogram of three scales, two of which are supported by parallel axes."

Ten pH values, as read from the chart and as calculated, show a standard deviation of ± 0.0158 .

A rapid method for determining soil moisture, E. M. EMMERT (*Soil Sci.*, 38 (1937), No. 1, pp. 31-36, fig. 1).—A method reported from the Kentucky Experiment Station is described as being "based on the fact that when water is added to concentrated sulfuric acid, a definite amount of heat is produced, proportional, within certain limits, to the quantities of water and acid mixed. With a fixed quantity of acid, the rise in temperature of the mixture will be definitely related to the quantity of water added and may serve as a measure of that quantity. Because the specific heat of water is greater than that of sulfuric acid, the rise in temperature when different quantities of water are added to a fixed quantity of acid is not exactly proportional to the quantity added but diminishes somewhat as the quantity of water is increased. Thus a series of such temperature readings, with fixed quantity of acid and increased quantities of water, could be plotted into a curve which would tend to flatten out as the quantity of water was increased."

On the determination of available phosphoric acid in acid or neutral soils by means of citric acid [trans. title], V. VINCENT (*3. Internatl. Cong. Soil Sci., Oxford, Eng., 1935, Trans., vol. 3, pp. 123-126*).—The author finds that for neutral or acid soils (but not for calcareous soils) the method of extracting with 2 percent citric acid solution, as here outlined, is adequate to show the quantities of phosphate in mineral form and immediately assimilable and to indicate the degree of importance of the organic combinations.

Absorption spectra in vitamin research [trans. title], H. RUDY (*Naturwissenschaften*, 24 (1936), No. 32, pp. 497-505, figs. 6).—The author reviews the chemical structures of vitamins A, B₁ (aneurin), B₂ (lactoflavine), C, D₂ (calciferol), and D₃ in relation to their characteristic spectroscopic absorptions.

A crystalline vitamin A concentrate, H. N. HOLMES and R. EL CORBER (*Science*, 85 (1937), No. 2195, p. 103).—In this preliminary note it is announced that a vitamin A concentrate distinctly crystalline to the naked eye has been prepared from the nonsaponifiable matter of the Ishinagi liver oil (*Stereolepis ishinagi*) by solution in a suitable solvent and fractionation by freezing at a temperature of solid carbon dioxide. Certain physical and chemical constants for the concentrate are given, with tentative values for carbon and hydrogen content.

Spectrographic studies on the antimony trichloride reaction for vitamin A.—I, The relation between tintometer readings and spectral absorption of the blue solution, O. NOREVAER and H. W. WEEDON (*Biochem. Jour.*, 30 (1936), No. 3, pp. 1705-1718, figs. 14).—A series of reactions with antimony trichloride reagent (concentration 220-225 g per liter of chromogenic substance) was carried out at $18^\circ \pm 0.5^\circ$ C., including one set made in a partial vacuum at about 30° , on samples of pure cod-liver oil and concentrates. The solutions were examined in the tintometer to determine blue values, and spectrographic measurements were made with 5 sec. as the standard time of exposure.

The blue solutions of the oils and concentrates in amounts varying from 0.05 to 0.4 cc followed Beer's law. This finding was confirmed spectrographically, and it is concluded that this lack of proportionality between blue readings and the concentration is a purely physical phenomenon. "The blue value, as read in the tintometer, of a solution with a given absorption maximum is 40-50 percent higher when the band lies at 618 $m\mu$ than when it lies at 603 $m\mu$. Even if the reaction were not inhibited by the oil, a concentrate should therefore always give a blue value nearly twice that of the corresponding oil if they are measured at the same reading."

A chemical reagent for the detection and estimation of vitamin B₁, H. J. PREBLUDA and E. V. MCCOLLUM (*Science*, 84 (1936), No. 2187, p. 488).—In this preliminary note it is stated that when a solution of either *p*-amino acetanilid or methyl-*p*-amino phenyl ketone (*p*-amino acetophenone) is treated with nitrous acid and the product formed by the reaction is treated under certain conditions with vitamin B₁ a characteristic purple red compound is formed which is stable and highly insoluble in water. The colored compound may be extracted quantitatively with a suitable solvent. The test is said to be extremely sensitive, the reaction taking place with quantities as small as several millionths of a gram of the active material.

Vitamin C in vegetables.—III, The oxidation of ascorbic acid by metallic catalysts, G. L. MACK and Z. I. KERTESZ (*Food Res.*, 1 (1936), No. 4, pp. 377-382, fig. 1).—This and the following paper from the New York State Experiment Station are in continuation of the series noted on page 280. The purpose was to determine the effect of traces of copper and iron occurring as impurities in the ordinary routine analysis on the determination of ascorbic acid in vegetables. A repetition with very pure materials of earlier work of Kellie and Zilva, which had led these authors to regard both iron and copper as catalysts for the oxidation, has led to the conclusion, confirming that of Barron et al. (*E. S. R.*, 75, p. 741), that iron alone does not catalyze the oxidation, but that in the presence of iron copper exerts an increased catalytic action.

The addition of 2 percent of metaphosphoric acid to the acid used to extract the ascorbic acid from vegetables, as suggested by Fujita et al. (*E. S. R.*, 76, p. 155), is recommended as an effective method to prevent any appreciable oxidation by copper in the time required for the analysis. The possibility that copper as contained in the vegetables might also exert a catalytic effect was tested by determining the ionizable or catalytically active copper in peas and snap beans. Only a small fraction of the total copper in peas and none of that present in snap beans appeared to be catalytically active.

It is emphasized that a reasonable amount of care should be exercised in the selection of reagents as free as possible from copper.

Vitamin C in vegetables.—IV, Ascorbic acid oxidase, Z. I. KERTESZ, R. B. DEARBORN, and G. L. MACK (*Jour. Biol. Chem.*, 116 (1936), No. 2, pp. 717-725, figs. 3).—This paper reports experiments dealing with the thermal inactivation of the enzyme which oxidizes ascorbic acid into dehydroascorbic acid and the importance of this enzyme from the standpoint of nutrition and food preservation. The extent of heating needed for the inactivation of the ascorbic acid oxidase in vegetables was determined by grinding the vegetable with an equal weight of water, immersing 5 cc of the mixture in boiling water for a definite period of time, cooling, adding 1 cc of a solution containing 0.5 mg of ascorbic acid, and keeping the mixture at 30° C. for 3 hr. Changes in the ascorbic acid content of the mixture were followed by titration with the indophenol dye. The relative catalase activity of the samples was determined at pH 7 by the usual method of estimation of the residual hydrogen peroxide after 1 hr.

The ascorbic acid oxidase in all samples was completely inactivated in 1 min., but the loss caused by nonenzymic catalysis was considerable during the 3-hr. period. In spinach the enzymic catalysis of the oxidation was rather slow, only a fraction of that observed in the cabbage extract, but the nonenzymic catalysis was more rapid than in any other vegetable studied. In all of the vegetable extracts the inactivation of catalase showed good correlation with that of ascorbic acid oxidase. Similar results were obtained with whole peas heated for different lengths of time. Both the oxidase and the catalase were completely inactivated by 1 min. of heating and the oxidase alone by $\frac{1}{2}$ min. of heating. In a further experiment with peas, vined (machine-shelled) Thomas Laxton peas were blanched in steam for 30, 60, 120, and 300 secs., quick-frozen, and stored at -7° for 2 mo., at the end of which time the ascorbic acid content of all the samples was determined chemically. The highest ascorbic acid value was in the sample which had been heated 1 min., the time found sufficient for complete inactivation of both ascorbic acid oxidase and catalase.

Inasmuch as ascorbic acid oxidase catalyzes the formation of dehydroascorbic acid, the question of the practical significance of the presence of this enzyme in plants is raised and answered by data showing the different stages in the decomposition of ascorbic acid in extracts of cabbage in the presence and absence of the oxidase. In the presence of the oxidase there is a rapid transformation of ascorbic acid into regenerable dehydroascorbic acid which, however, is slowly changed into a physiologically inactive substance, while in the presence of the enzyme the conversion of ascorbic acid into dehydroascorbic acid is very slow.

Some relations between ascorbic acid and glutathione, F. G. HOPKINS and E. J. MORGAN (*Biochem. Jour.*, 30 (1936), No. 8, pp. 1446-1462, figs. 13).—The authors describe experiments which demonstrated the action of the ascorbic acid oxidase of cauliflower on ascorbic acid and reduced glutathione. The enzyme which rapidly oxidized ascorbic acid to dehydroascorbic acid caused the oxidation of reduced glutathione only in the presence of ascorbic acid. The glutathione was oxidized at the same rate as the ascorbic acid, but the oxidation of the ascorbic acid did not begin until the glutathione had practically disappeared from the system. The opinion of Szent-Györgyi that this action is due to continuous reduction of the dehydroascorbic acid formed is confirmed, since the dehydroascorbic acid in the presence of the oxidase and of reduced glutathione was reduced by the reduced glutathione at a much quicker rate than that at which ascorbic acid was oxidized by the oxidase.

The presence of glutathione also protected the ascorbic acid from oxidation by copper catalysis by forming a stable compound with the copper and so preventing efficient contacts between the metal and its substrate. From the results of experiments to determine the behavior of ascorbic acid and glutathione in aerated hepatic tissue, it would appear that normally the two substances are oxidized independently, perhaps by different agencies.

The enzyme is believed to be identical with the hexoxidase of cabbage described by A. Szent-Györgyi¹ and probably also with the similar enzyme of squash (*Cucurbita maxima*) described by Tauber et al. (*E. S. R.*, 74, p. 442).

Value of the acid silver nitrate reaction as a test of ascorbic acid, A. GIBOUD and C. P. LEBLOND (*Nature [London]*, 138 (1936), No. 3484, pp. 247, 248).—Attention is called to the criticisms of the specificity of the silver nitrate reaction for ascorbic acid expressed by several investigators, including Harris

¹ *Jour. Biol. Chem.*, 90 (1931), No. 1, pp. 385-393, figs. 3.

and Ray (E. S. R., 72, p. 731), Dann and Cowgill (E. S. R., 75, p. 285), and King (E. S. R., 75, p. 571). Evidence is summarized in support of the view that the reduction, without the action of heat and light, of silver nitrate acidified with acetic acid is a very specific test for ascorbic acid, but that a negative reaction does not necessarily mean the absence of ascorbic acid. The chief reason for the occasional failure of the test is thought to be the presence in the organs tested of factors inhibiting the reduction of ascorbic acid.

Observations on the use of the phosphotungstic acid method of determining ascorbic acid in urines with low ascorbic acid content, G. MEDES (*Biochem. Jour.*, 30 (1936), No. 9, pp. 1753-1755).—Referring to a previous study (E. S. R., 75, p. 744), the author presents special precautions that must be employed in using the phosphotungstic acid method on urines containing less than 4×10^{-4} g mol ascorbic acid per 100 cc. Color interference may be taken care of by introducing a few drops of an indicator such as bromophenol blue, using a color filter, or backing the standard by urine diluted similarly to that in the test solution. The faint cloudiness which frequently develops in urines extremely low in ascorbic acid may be removed by centrifuging. The colorimetric readings should be taken immediately at the close of the 20-min. period (20 ± 5 min.).

In a series of tests on four urines of low ascorbic acid content the colorimetric method was compared with the titration method, and it was concluded that the two methods are about equally accurate when the ascorbic acid concentration in the urine is very low. The colorimetric method proved to be more accurate when the ascorbic acid concentration of the urine had been increased by the addition of increments of standardized ascorbic acid.

Energy equivalents of vitamin D units, R. W. HAMAN and H. STEENBOCK (*Indus. and Engin. Chem., Analyt. Ed.*, 8 (1936), No. 4, pp. 291-293, fig. 1).—In this study at the Wisconsin Experiment Station the authors have used a technic similar to that described by Marshall and Knudson (E. S. R., 64, p. 504) to determine the amounts of radiant energy required to synthesize 1 international unit and 1 Steenbock unit of vitamin D, using ergosterol as the substrate. The values obtained were 900 and 3,000 e, respectively, independent of the wavelengths within the synthesizing region. This ratio of 1:3.33 has been found to check with biological tests. One Steenbock unit of vitamin D is thus equivalent to 3.33 international units instead of 2.7 units as adopted provisionally.

Accuracy of certain methods used in analysis of sauerkraut, O. S. PEDERSON and C. D. KELLY (*Food Res.*, 1 (1936), No. 3, pp. 277-286, figs. 5).—In an investigation carried out at the New York State Experiment Station, the authors have shown that salometer readings are so affected by the various ingredients in kraut juice, such as acid, sugar, suspended solids, alcohol, and proteins, that they are of little or no value for estimation of the salt content. Direct titration of the juice with silver nitrate, using potassium chromate as an indicator, was found sufficiently accurate for practical use, however. The salometer reading could be used as a fair indication of the total solids in kraut juice but not of salt alone.

"Absolute uniformity, particularly in regard to salt, is difficult to obtain in a vat of kraut. The salt of the juice in the well is usually higher than that in the center of the vat, although the salometer reading is nearly always lower. Weighing salt and shredded cabbage is apparently the only absolute method of establishing a definite salt content in kraut.

"The direct titration of acid in sauerkraut juice, using phenolphthalein as an indicator, gives results that are somewhat low, but they are comparable

and therefore valuable. Liberation of organic acids by mineral acids is essential to complete extraction and steam distillation of organic acids. Volatile acid determinations are somewhat variable and quite dependent upon the amount of extract collected."

Effect of processing and storage on composition and color of honey, E. G. LYNN, D. T. ENGLIS, and V. G. MILUM (*Food Res.*, 1 (1936), No. 3, pp. 255-261, fig. 1).—At the University of Illinois, a sweetclover honey was extracted and strained, and separate lots were heated for 30 min. at 82.2°, 71.1°, and 62.8° C., respectively. Samples from each lot were placed in screw-top jars and stored at constant temperatures of 36.6°, 25°, and 4.4° for a year. They were then examined for certain chemical and physical changes.

"The moisture content decreased markedly with increase in storage temperature. Certain irregularities are probably due to variation in the tightness of the cap. Reducing sugars increased slightly with increase in storage temperature. The samples with the higher processing temperature showed the greater increase. The total nitrogen content of samples representing extremes of treatment showed no significant difference. The amino nitrogen decreased with increase in storage temperature, but the actual amount present at any time was small. Coloration, on the other hand, increased with increase in temperature. The samples stored at the higher temperature showed a marked increase in absorption for the light of shorter wavelengths of the visible spectrum and little change for the longer wavelengths. It is believed that darkening of the samples is due primarily to instability of the fructose of honey."

A note on the nitrogenous constituents of dried apricots during browning, C. L. BEDFORD (*Food Res.*, 1 (1936), No. 4, pp. 337-339).—"From the data obtained . . . [at the University of California] it appears safe to conclude that the changes in the N fraction of the water-soluble material from apricots on darkening are slight, and it is doubtful that they or the sugars are involved in the darkening."

The brown pigment formed in the concentrated extract or in the dried fruit itself is water-soluble. Most of it is readily precipitated from concentrated aqueous solution by adding alcohol or acetone. It is also precipitated by lead acetate and is recoverable by deleading with hydrogen sulfide or diluted sulfuric acid, followed by precipitation with acetone. This precipitate is insoluble in ethyl ether, petroleum ether, benzol, and ethyl acetate. It contains about 1 percent of nitrogen.

"Whether the N represents a combination of a nitrogenous compound and some other compound of the fruit or is merely adsorbed N or some other form of uncombined N compound is yet to be determined."

Home fruit bottling (*Univ. Leeds and Yorkshire Council Agr. Ed. [Pam.] 184* (1936), pp. [4], fig. 1).—This pamphlet gives brief information on the selection of fruit, types of bottles, the preparation of a home-made wax seal, and the packing and sterilizing of the fruit and sirup.

The cooking process.—IX, Pulping wood with alcohols and other organic reagents, S. I. ARONOVSKY and R. A. GOETNER (*Indus. and Engin. Chem.*, 28 (1936), No. 11, pp. 1270-1276, figs. 3).—This contribution from the Minnesota Experiment Station reports experiments carried out under conditions very similar to those of earlier work (E. S. R., 74, p. 594) save that the cooking medium consisted of equal volumes of the organic solvent and distilled water. The solids glucose, mannitol, and urea were applied as aqueous solutions of various concentrations.

"The normal primary alcohols were better pulping agents than the secondary or tertiary alcohols. Normal butyl and amyl alcohols yielded better pulped residues than were obtained with the other alcohols. There appeared to be a definite relation between the aqueous solubilities of the monohydroxy alcohols and their pulping properties. The pulping efficiencies of the alcohols also seemed to be related to the zeta potentials at the cellulose-alcohol interfaces. Aspen chips cooked with normal butyl alcohol yielded a pulp which was comparable to the usual commercial aspen soda pulp in strength characteristics. Coniferous woods were not pulped by butyl alcohol as readily as the aspen. The residual liquors of the cooks made with normal butyl and amyl alcohols consisted of two layers—the top alcoholic layer contained the organic substances extracted from the wood and the lower aqueous layer contained only small quantities of water-soluble substances. This pulping procedure provides a means of obtaining the ligneous material of the wood uncontaminated by inorganic compounds not present in the original wood."

Some of the properties of the extracted ligneous material are stated.

AGRICULTURAL METEOROLOGY

Agricultural meteorology, L. A. RAMDAS and M. S. KAVI (Indian Jour. Agr. Sci., 4 (1934), No. 6, pp. 923-937, figs. 4; 6 (1936), No. 6, pp. 1163-1200, pl. 1, figs. 10).—In a study of soil moisture in relation to moisture in the surface layers of the atmosphere during a clear season, evidence was obtained that evaporation of moisture from a soil surface containing only hygroscopic water and the reverse phenomenon during night, viz, the absorption of moisture from the air layers near the ground by the desiccated soil surface, exert a controlling influence on the distribution of moisture with height in the air layers. Studies in laboratory and field of diurnal variation in the moisture content as determined by two-hourly measurements were made with representative soils from different parts of the country, the soils being under identical conditions in each case. These studies showed that "there is a conspicuous exchange of moisture between the soil surface and the air layers above it, the intensity of this exchange is a characteristic property of each soil, and the epochs of maximum and minimum moisture contents of the soil coincide with those of minimum and maximum temperatures respectively."

The results further showed that except for specific heat and true specific gravity the following properties of soils vary in a similar manner: "Diurnal variation of moisture, water-holding capacity, absorption of moisture in a definite time interval under steady laboratory conditions, and heat of wetting."

The determination of sodium chloride content of air, H. P. GODDARD and W. F. SEYMOUR (Roy. Soc. Canada, Trans., 3, ser., 30 (1936), Sect. III, pp. 85-88, fig. 1; abs. in Sci. Abs., Sect. A—Phys., 40 (1937), No. 469, pp. 36, 37).—By means of a method of filtering the air coming from all directions along the coast of Vancouver and determining its chloride content, there was found to be no correlation between wind direction and salt content, but cold clear days and days of high relative humidity showed a high salt content. A special apparatus for making observations over the sea or close to the sea is described.

A simple device for recording the time and duration of rainfall, R. R. HERR (Phytopathology, 26 (1936), No. 11, pp. 1064-1067, figs. 2).—The device consists of a revolving disk actuated by the mechanical parts of a standard alarm clock, mounted in a wooden case. An opening in the cover permits drops of rain to fall on a circular record sheet attached to the revolving disk, the accuracy of the record being regulated by the size of the opening. Each record

sheet is divided by radial lines into 24 equal sectors, representing $\frac{1}{2}$ -hr. intervals, and concentric circles are drawn with indelible lead on these sheets. The time and duration of rainfall are recorded as colored spots or washed streaks. The device is useful in epidemiology studies where the time and duration of rainfall is a factor.

Evaporating power of the air and humidity of the soil [trans. title]. H. GESLIN (*Compt. Rend. Acad. Sci. [Paris]*, 203 (1936), No. 21, pp. 1095-1097, fig. 1; abs. in *Sci. Abs., Sect. A—Phys.*, 40 (1937), No. 469, p. 37).—A comparison of observed and calculated evaporation from the soil is reported which showed that the calculated humidities corresponded well with the observed humidities, also, that a soil humidity of 25 percent on the scale adopted characterizes the capacity of the soil for retention of precipitation. By this means there is provided a simple method for knowing at each instant from ordinary climatological data the reserves of water in the soil and of determining fluctuations of these reserves with time.

Index characterizing the factor of drought in agronomy [trans. title], J. SERVY (*Compt. Rend. Acad. Sci. [Paris]*, 203 (1936), No. 21, pp. 1097-1100, fig. 1; abs. in *Sci. Abs., Sect. A—Phys.*, 40 (1937), No. 469, p. 37).—"In previous work (E. S. R., 73, p. 585) simple formulae based on the ratio P/E (rain/evaporation) were sought for as characterizing the dryness factor. Now the index $R = \Sigma(P)/\Sigma(E)$ taken over a period tends towards a constant. To avoid this a new index is devised. This new factor R is such that the influence of any given month decreases with time, so that the effect of that particular month is soon negligible. The relation between R and the humidity H of the soil is then considered and a graph drawn for the years 1932-36. An expression of the form $R = a^{H^m}$ is deduced. From the investigation the author concludes that to each type of soil there is therefore a relation $R = a^{H^m}$ characterizing its real ability to retain water, i. e., to maintain its reserves in given climatic conditions."

Climate and yield of wheat in the region of Paris [trans. title], H. GESLIN and J. SERVY (*Compt. Rend. Acad. Agr. France*, 23 (1937), No. 5, pp. 146-152, fig. 1).—This is an account of a study of precipitation and drought as related to the yield of wheat and of water-holding power of the soil. The maximum yield was obtained with a precipitation of about 290 mm, which is 70 percent of the normal. The highest yield was obtained in 80 percent of the cases when the rainfall during the growing period was below normal. There was a decline in yield in 75 percent of the cases when the rainfall was above normal. In the regions studied, where the reserves of moisture are usually renewed in the fall, a dry year appears to be a good year for wheat. More important than amount and distribution of rain in time were the reserves of moisture in the soil (factor of dryness), for which a formula is given based on water added to the soil and that lost by evaporation.

Rainfall, humidity of the soil, and climate from the agronomic point of view [trans. title], H. GESLIN and J. SERVY (*Ann. Agron. [Paris]*, n. ser., 7 (1937), No. 1, pp. 85-101, pl. 1, figs. 3).—This is substantially a more extensive account of investigations by the same authors noted above. It emphasizes the agronomic importance of amount and distribution of rainfall as a climatic factor, especially conditions determining the reserves of water in the soil, and gives a simple method (index) of estimating the amount of soil moisture (drought factor) which may be expected under a given set of conditions.

Influence of Mediterranean forests on climate [trans. title], A. PAVARI (*Geografich. [Firenze]*, 6. ser., 2 (1936), No. 4, pp. 475-501, pls. 3, figs. 11).—This

article discusses in general and reports observations on the influence of different kinds of forests on climate, with special reference to Italian conditions. It deals particularly with effect on temperature and moisture of the soil and the air and on wind movement.

SOILS—FERTILIZERS

New trends in soil science [trans. title], A. A. JARELOW (3. *Internatl. Cong. Soil Sci., Oxford, Eng., 1935, Trans., vol. 3, pp. 172-177*).—The author outlines certain changes in the viewpoint of Russian soil science since 1920. The tendency to turn from the purely scientific viewpoint toward that which regards soil science as also one of the bases of an agricultural industry is emphasized.

The present development of soil study in China, T. Y. TANG (3. *Internatl. Cong. Soil Sci., Oxford, Eng., 1935, Trans., vol. 3, pp. 136, 137*).—This author states that "about the year 2210 B. C., Da Yu, the first emperor of the Hsia dynasty, took up the study of the soils of nine territories and classified them according to their color, texture, geographical features, and productivity for the purposes of evaluation and assessment of land taxes. Although the classification can hardly be regarded as scientific from the modern pedological standpoint, still it must be considered remarkably comprehensive and systematic for that early period when scientific knowledge was so limited." Recent soil studies have been of limited extent and mostly confined to fertility questions. A comprehensive study of the soils of China was begun, however, in 1930. The progress of this work is outlined.

[**Soil investigations of the Delaware Station**] (*Delaware Sta. Bul. 205* (1936), pp. 18, 19, 25, 26, 45, 46).—Notes are given on the effect of lime on the availability of potash on soils, by H. C. Harris; the effect of fertilizers and cropping upon the nature and amount of electrolysable bases in the soil, with particular reference to potassium, by G. M. Gilligan; and the influence of copper and zinc salts on the soil flora, by T. F. Manns, W. L. Churchman, and M. M. Manns.

[**Soil investigations of the Iowa Station**] (*Iowa Sta. Rpt. 1936, pts. 1, pp. 50, 51, 63-70, 109; 2, pp. 9-20, fig. 1*).—The report contains in part 1 concise summaries of work on the value of sweetclover as a soil-building crop, by P. E. Brown, J. L. Boatman, and L. W. Forman; the occurrence and activities of *Azotobacter* in Iowa soils as influenced by soil treatment, utilization of carbonaceous materials by *Rhizobium*, effects on crop yields and soil conditions of small applications of fine limestone drilled in the row for starting new seedlings of legumes on acid soils, and the occurrence and activities of legume bacteria in acid soils as influenced by soil treatment, all by R. H. Walker; the decomposition of lignin in soils, decomposition of leguminous green manures in acid and limed soils, relation of carbon dioxide in soils to the availability of phosphorus and potassium, and the decomposition of some humus-forming materials in soils, all by F. B. Smith; the relation between the capillary tension and the moisture content of soil as determined by porous ceramic cells and relation of capillary conductivity to the capillary tension and moisture content of soil, both by L. A. Richards; soil erosion reconnaissance survey of Iowa, by Walker, Brown, R. E. Uhland, and W. DeYoung; the basin method of treating pastures to prevent erosion and run-off, by E. V. Collins; and the relation of plant cover to erosion control, by J. M. Aikman and A. F. Dodge.

Part 2 contains statements of progress on the effects of fertilizers under various rotations and effects of various amounts of fertilizers applied at different times in the rotation on crops and soil conditions in the Wisconsin

drift soil area, and character, fertilization, and management of high lime and alkali soils of Iowa, all by Brown, Boatman, and Forman; effects of various fertilizing materials on crop growth on the Carrington, Grundy, Tama silt, terrace and bottomland, and Webster soils and on the chemical and bacteriological conditions in the soils, all by H. R. Meldrum and A. J. Englehorn; the effects of various fertilizing materials on crop growth on the Clarion loam and Marshall silt loam, and on the chemical and bacteriological conditions in the soil, both by Meldrum; effects of various fertilizing materials on crop growth on the Muscatine silt loam and Clinton silt loam on the chemical and bacteriological conditions in the soil, both by Englehorn; plant food content and lime requirements of Iowa soils and the composition of various crops, by Brown and Englehorn; and soil erosion on the Marshall silt loam in Page County, Iowa, by Brown, Smith, G. B. MacDonald, J. B. Davidson, H. D. Hughes, O. R. Neal, and R. A. Norton.

[Soil chemistry investigations of the New Mexico Station] (*New Mexico Sta. Rpt. 1936, pp. 47, 48, 50*).—This station reports briefly on effects of irrigation and cropping on soil profiles, on irrigation waters, on the soluble matter of the soil profiles, and on the colloids of Gila clay adobe.

A method of land classification, L. E. TAVENER (*3. Internatl. Cong. Soil Sci., Oxford, Eng., 1935, Trans., vol. 3, pp. 140, 141*).—"Since the development of the land at any particular time depends not only on the physical factors which determine what the land can produce but also on the economic factors which determine what shall be the development, the soil map should form only part of the basis of land classification." Maps exhibited by the author to Commission V were constructed on the double basis of soil survey data and crop and livestock distribution.

The land classification scheme of the Land Utilisation Survey of Britain, L. D. STAMP (*3. Internatl. Cong. Soil Sci., Oxford, Eng., 1935, Trans., vol. 3, pp. 138-140*).—"The scheme of land classification adopted by the Land Utilization Survey of Britain is based essentially on existing land use. . . . The main object of the survey has been to record the present use of every acre of England, Wales, and Scotland."

Six main categories are represented each by a letter symbol and a color. Subclassification is by secondary letter symbol only. The land classes are forest and woodland; arable land; permanent pasture and meadowland; heath land, moorland, and rough pasture; gardens, nurseries, and orchards; and land agriculturally unproductive.

"The maps based on this scheme of classification are clearly in no way substitutes for soil maps, nor do they attempt to evaluate the potentiality of the land. Rather are they supplementary, and a comparison with a soil map will at once reveal areas which are underutilized, but the maps provide (1) a standard of comparison with the past and (2) a basis of planning for the future."

Principles of the genetic classification of soils, B. B. POLYNOV (*3. Internatl. Cong. Soil Sci., Oxford, Eng., 1935, Trans., vol. 3, pp. 158-161*).—In considering effects of weathering for genetic soil classification purposes, the author finds it "necessary to distinguish two forms—residual and accumulative weathering crusts.

"The residual crust of weathering or true eluvium is a product of a series of stages, the principal of which are: (1) Debris stage, i. e., the products of mechanical weathering; (2) calcified stage, when the products of weathering lose their most mobile constituents (compounds of Cl and S) and become richer in CaCO_3 at the expense of the Ca of silicates and the CO_2 of the air;

(3) siallite saturated stage, when the products of weathering lose not only compounds of Cl and S but also CaCO_3 , leaving the adsorption complex, however, saturated with Ca; (4) siallite unsaturated stage, when hydrogen begins to take a place among the adsorbed cations; (5) allite stage, when not only Cl, S, and bases are lost but also the Si of silicates, leaving behind the iron and alumina and the silica of quartz.

"But in addition to these we have the accumulative forms of the crust of weathering, i. e., deluvial, proluvial, alluvial, etc., deposits which in dependence on time and place become enriched with mobile compounds and clay: (1) Chloride-sulfate accumulative crust of weathering enriched with chlorides and sulfates; (2) carbonate accumulative crust of weathering enriched with CaCO_3 but devoid of chlorides and sulfates which have been washed out (loess); (3) siallite accumulative crust of weathering deposits which have lost chlorides, sulfates, and carbonates but which may still contain mobile SiO_2 , Al, and Fe. It cannot be doubted that the distribution of the various forms of the crust of weathering is dependent not only on climate but also on relief and time." On the basis of the above considerations and concepts developed from them, "the first part of a genetic classification of soils ought to be built."

The second, and equally essential, basis for genetic soil classification, in the the author's opinion, lies in "the method of concurrent analyses in which we analyze not only the horizons of the soil but the ash of those plants which are growing on that profile." An illustrative example of the value of such concurrent analyses of plant material and the soil affected by the vegetation in question is presented in the form of analyses of an Adzharian soil and of parts of the plant material growing upon it. "The ultimate analysis of soils under that vegetation showed that the uppermost layer in the soil profile always contains distinctly more Al_2O_3 than the lower ones. . . . This distribution of Al_2O_3 shows sufficiently clearly that it is returned to the soil in the falling leaves when these decompose. This explained to us that peculiarity of Adzharian soils which until now had not been understood. It explained why, notwithstanding the very favorable conditions, we do not find a typical development of the Podzol profile."

Soil mineralogy applied to problems of classification, R. HART (3. *Internat. Cong. Soil Sci., Oxford, Eng., 1935, Trans., vol. 3, pp. 161, 162*).—"In Scotland, from field studies of soils it is recognized that of the several factors influencing the development of the soil geological conditions must be taken into account to explain the occurrence of different soil types under exactly similar climatic and topographic conditions. For instance, in the east and southeast of Scotland Brown soils occur quite generally in areas where podzolized soils may also be found on different parent materials. In the northeast region also striking effects of geological conditions on soil development may be seen. In a region of fairly uniform climate the change in soil type is as marked as the change in geological structure. Here occurs a series of rock types, granites and granitic gneisses, diorites and gabbros, and slates, and marked differences in soil types are found associated with the different rocks. The influence of these basic rocks on the soil type is definitely marked in the development of Brown earth soil types over them in contrast to the podzolized types over the acidic rocks. The study of the mineralogical composition of soils is therefore of service for the determination of the parent material and for the study of the changes resulting through weathering. It also serves as an aid in determining the state of development of the soil type and its position in a genetic scheme of classification."

Relations between the crystal-structure of minerals and their base-exchange capacity, C. H. EDELMAN (*3. Internatl. Cong. Soil Sci., Oxford, Eng., 1935. Trans., vol. 3, pp. 97-99*).—The author summarizes the purpose of the present brief discussion in the statement that “in this paper we intend to prove that the ideal lattices of the several mineral groups show differences which correlate with the adsorption properties found in an empirical way. That these differences in structure are the real causes of the differences in the adsorption capacity will be made probable.”

Cultivated plants and the adsorbed cations of the podzolic soil [trans. title], O. K. KEDROW-SICHMANN (*3. Internatl. Cong. Soil Sci., Oxford, Eng., 1935. Trans., vol. 3, pp. 118-122*).—The author very briefly summarizes experiments on the relation of plant growth to the cations contained in the adsorption complex, drawing numerous conclusions, among which are the following:

The optimal combination of adsorbed bases is dependent upon the individual characteristics of the various plants. When the adsorption complex is not saturated with bases, the power of the soil to support growth can be improved not merely by additions of the calcium ion but by also adding various other ions, as, for example, those of magnesium, sodium, potassium, ammonium, and manganese. Agricultural plants were able to make good growth even when these last-named bases were present in a much larger proportion than has generally been considered permissible. Magnesium carbonate which had not entered into reaction with the soil was found to have a markedly unfavorable effect even when the quantity present in the soil was very small. The ill effect of undecomposed magnesium carbonate in the soil could be counteracted by sufficiently large additions of calcium carbonate.

[Soil Survey Reports, 1932 Series] (*U. S. Dept. Agr., Bur. Chem. and Soils [Soil Survey Rpts.], Ser. 1932, Nos. 12, pp. 31, figs. 2, map 1; 13, pp. 46, figs. 2, map 1*).—These reports were prepared with the cooperation of the Alabama Department of Agriculture and Industries and the Virginia Experiment Station.

No. 12. *Soil survey of Winston County, Alabama*, M. E. Swann et al.—Winston County consists of 403,200 acres of generally rough or hilly lands in north-western Alabama. Certain terraces and first bottoms are ill drained, the remaining soils well drained. These better drained soils have been for so long a time subject to leaching that they “are naturally low in mineral plant nutrients. They are highly deficient in organic matter and, therefore, nitrogen, one of the most important plant nutrients, and their inherent productivity is low.”

The soils of this area were found to constitute 7 series of 8 types. The most extensive of the classifiable soils as listed is Hartsells very fine sandy loam, of which the greater part takes the form of a rolling phase. This soil covers 24.1 percent of the county. Unclassified and nonagricultural areas total 48.4 percent of the county. They consist mainly of 25.2 percent of Guin soils, undifferentiated, and rough stony land, 23 percent.

No. 13. *Soil survey of Augusta County, Virginia*, R. C. Journey et al.—Augusta County consists of 636,800 acres of valley land between mountainous borders, for the most part adequately drained, in northwestern Virginia.

The soils are here mapped and described as 15 series containing 28 types. Muskingum stony fine sandy loam, steep phase, is the most extensive soil of the county, of which it constitutes 22.2 percent. “The relief is steep and broken, and none of the land is used for crops.” Frederick silt loam, including gravelly, hilly, and stony phases, makes up a further 17.7 percent of the county.

Soils of Iowa, P. E. BROWN ET AL. (*Iowa Sta. Spec. Rpt. 3 (1936)*, pp. 261+4, figs. 485).—This is a general summary of soil survey findings to date and of related results of soil investigations, including field experiments. The chapters and their authors are as follows: The soils of Iowa, the soil survey, and the soil types of Iowa, all by Brown; the geology of Iowa and the soil areas of Iowa, both by B. J. Firkins and Brown; the phosphorus, nitrogen, and carbon content of Iowa soils, by R. H. Walker and Brown; productivity ratings for Iowa soils, by Brown, T. H. Benton, and C. L. Orrien; and field experiments on some of the major soil types in Iowa, by Brown, H. R. Meldrum, and A. J. Englehorn.

A soil survey of the sugar beet soils in southern Sweden, O. ARRHENIUS (*3. Internat. Cong. Soil Sci., Oxford, Eng., 1935, Trans., vol. 3, pp. 122, 123*).—The survey mentioned covered about 500,000 ha (1,235,000 acres) and involved the determination of pH value, available phosphate, nitrate production, and chlorine content. The author deals here only with the general nature of the value of the phosphate determinations and the maps, prepared for the use of farmers, which show where and in what quantities phosphatic fertilizers are needed.

New map of the soils of Russia [trans. title], L. I. PRASOLOV (*3. Internat. Cong. Soil Sci., Oxford, Eng., 1935, Trans., vol. 3, pp. 132-136*).—The author presents a general description of a new map, to the scale of 1 cm: 10 km, of which 20 sheets, representing about 3,000,000 sq. km, have been completed. The soils of the plain of eastern Europe were divided, for the purposes of the map, into the three series eluvial soils, the salinization and desalinization series, and marsh and swampy meadow soils. The first of these series, comprising the greater part of the soils mapped, is further subdivided.

Soil maps of Spain and Morocco, E. H. del VILLAR (*3. Internat. Cong. Soil Sci., Oxford, Eng., 1935, Trans., vol. 3, p. 132*).—This note very briefly describes two soil maps, drawn to the scales 1:400,000 and 1:1,500,000, respectively, of the Luco-Iberian Peninsula and of Morocco. The soils shown on these maps are named, and the method of mapping them is indicated.

Some comments on the soils of Tunisia [trans. title], V. AGAFONOFF (*3. Internat. Cong. Soil Sci., Oxford, Eng., 1935, Trans., vol. 3, pp. 137, 138*).—The author, who has recently completed a tour of about 9,000 km (5,580 mi.) made for the purpose of a field study of the soils named, attributes the natural development of Tunisia to the struggle between the influences of the Mediterranean and the Sahara. In spite of the capricious irregularities of the climate, he found it possible to set apart four climatic divisions, namely, the northern zone, having from 600 to 1,500 mm of rainfall annually; an intermediate zone, from 400 to 600 mm; a central zone, from 150 to 400 mm; and a southern zone, having less than 150 mm (6 in.) of rainfall annually. The nature of the soil development which has taken place under each of the first three climatic influences is outlined.

Some observations on the soils of tropical Africa, C. G. T. MORISON (*3. Internat. Cong. Soil Sci., Oxford, Eng., 1935, Trans., vol. 3, pp. 141-145*).—"It was found possible to delimit the area into three important units, in the first of which the rainfall was about 250 mm [10 in.] per annum and fell in the months of August and September. In the second area the rainfall averaged 760 mm and occurred in the months of July, August, and September. In the third area the rainfall was from 1,500-2,000 mm and fell in the 6 mo. from April to September. It was found possible to distinguish certain main types of soil and their associated vegetation which appeared to persist throughout the

three regions, and from which it was consequently possible to deduce certain general statements with regard to tropical soil." Certain main factors upon which the nature of the soils is held to depend and topographic characteristics of the terrain are indicated, and the general outline of the classification scheme is presented.

Some aspects of the black cotton soils of Central Provinces, India, D. V. BAL (3. *Internatl. Cong. Soil Sci., Oxford, Eng., 1935, Trans., vol. 3, pp. 154-158*).—"The lime content of these soils generally varies inversely with the rainfall of the localities in which they are found. Appreciable amounts of calcium and silica are leached from the surface soil. A certain amount of clay is also washed down continually from the surface soil. These soils contain a low percentage of nitrogen and organic matter. The rate of (1) biological oxidation of organic matter, (2) formation of ammonia and nitrates from organic nitrogen is very vigorous. In these heavy soils the biological activities are at their best when the moisture content is about half the maximum water-holding capacity. Nitrification in artificially watered soils previously air-dried is slower in starting than with soils receiving natural rainfall, but the nitrifying efficiency after a period of 8 weeks is about the same. A heavy clay soil which has lost its texture shows at first a diminished nitrifying power when compared with the same type of soil in good condition. The nitrifying organisms of the soil can tolerate a fairly high concentration of free ammonia and form nitrates from it in the soil."

Some important soil groups of Ceylon, A. W. R. JOACHEIM (3. *Internatl. Cong. Soil Sci., Oxford, Eng., 1935, Trans., vol. 3, pp. 148-154*).—"The author finds that major soil groups of the island of Ceylon may be classified as follows: The laterite soils, the red and yellowish lateritic and nonlateritic earths; soils similar to the Terra Rossa soils; the mountain steppes (Patanas); soils derived from Pleistocene and recent deposits; and the paddy (Gley) soils.

He presents a short general statement of the delimiting characteristics of each of these groups, illustrating in each case with the profile description and horizon analyses one or more members of the group.

Soil surveys in the Netherlands Indies, H. J. te RIELE (3. *Internatl. Cong. Soil Sci., Oxford, Eng., 1935, Trans., vol. 3, pp. 145-147*).—"In the Netherlands Indies, soil surveys are carried out, both on behalf of the Government and by the several private experimental stations, for specific crops." The various methods and viewpoints of the surveys carried out by these separate agencies are outlined.

Report of proceedings of the Seventh Southwest Soil and Water Conservation Conference (7. *Southwest Soil and Water Conserv. Conf., Stillwater, Okla., 1936, Proc., pp. 83*).—"These proceedings contain special reports on Progress of Soil Conservation Work in Region Four, by L. P. Merrill (pp. 5-8); The Progress Made in Wind Erosion Control in the Southern High Plains Region, by H. H. Finnell (pp. 9-11); The Outstanding Experimental Results in Erosion Control at Temple, Texas, by E. B. Deeter (pp. 12-14); Watershed and Hydrologic Studies, by C. E. Ramser (pp. 14-22); Progress in the Central Plains Area—Region No. 7, by N. E. Winter (pp. 22, 23); Soil and Water Conservation Investigations, by G. W. Musgrave (pp. 40-45); Recommendations for Research Relating to the Control of Wind Erosion, by H. V. Geib (pp. 45-51); Soil and Water Conservation on Land Utilization Projects in Oklahoma and Texas, by G. Briggs (pp. 51-54); A Study of Gully Formation and Control in Oklahoma, by H. J. Harper (pp. 54-64); The Cost of Terracing With Power Equipment, by D. G. Carter and W. C. Hulbert (pp. 64-68); The Importance of Vegetative Growth on Erosion Control, by A. E. Aldous (pp. 69-72); and

Grass and Legume Studies in Connection With Pasture Improvement and Erosion Control at the Red Plains Soil Conservation Experiment Station, by H. M. Elwell (pp. 72-75).

Some aspects of soil erosion control in the United States, H. KOHNKE and J. S. CUTLER (*3. Internatl. Cong. Soil Sci., Oxford, Eng., 1935, Trans., vol. 3, pp. 177-180*).—The authors, both of the U. S. D. A. Soil Conservation Service, summarize the present erosion situation in the United States in the statement that "it may be said that the safe use of land in different areas depends upon the productive capacity and the slope of the land. In general, the more gentle slopes can be economically protected from excessive erosion by purely agronomic methods, such as fertilization, planned crop rotations, strip cropping, and contour tillage, or by the use of terraces. The steeper lands can be economically utilized as meadow or pasture, while the excessively steep slopes can best be devoted to forest, climatic conditions permitting, or to pasture. Farm management studies have shown that the adoption of erosion control methods will result in no immediate loss of return and over a period of years actually increase the income of the farmer."

Comparison of runoff and erosion in prairie, pasture, and cultivated land, J. E. WEAVER and W. C. NOLL (*Nebr. Univ., Conserv. and Survey Div., Conserv. Dept. Bul. 11 (1935), pp. 37, figs. 11*).—The results of run-off and erosion measurements from entire watersheds and from run-off plats are presented and discussed.

Enclosed plats 3 ft. wide and 33.3 ft. long were used in these studies. Natural rainfall was supplemented by artificial watering. Run-off on a 10° slope from 26.88 in. of rainfall during 15 mo. was 2.5 percent from prairie, 9.1 from overgrazed pasture, and 15.1 percent from a pasture entirely hared by close grazing. The soil was Carrington silt loam. No measurable amount of soil eroded from the prairie, and only a small amount from the pasture, but 5.08 tons per acre were lost from the bare area.

Run-off from 4 in. of water applied to pasture and prairie, respectively, in July 1934, at the rate of 2 in. per hour (including 1 in. applied in 15 min.) at intervals 2 weeks apart, resulted in 3.1 and 9.8 percent run-off. In April of the next year 2.5 in. were applied at the same rate to prairie, pasture, and bare area. Run-off losses were 0, 29.3, and 50.4 percent, respectively, and losses by erosion at the rate of 0, 165 lb., and 3.42 tons of soil per acre.

In October, after another summer of close grazing and root deterioration, 3 in. of water were applied in 1.5 hr. to each area. Run-off from prairie, pasture, and bare area was 11.3, 50.5, and 71.6 percent, respectively, and soil losses from erosion at the rate of 0, 355 lb., and 4.67 tons per acre. Water penetration was nearly four times as great in prairie as in pasture.

Run-off on a 5° slope from 12.9 in. of rainfall during a period of 11 mo. was 1 percent from the prairie, 12.1 from wheatfield, and 17.8 percent from fallow land. The soil was Carrington silt loam. No measurable erosion occurred in prairie. 0.52 ton of soil per acre eroded from the wheatfield, and 2.6 tons from the fallow land.

Five in. of water were applied to prairie and wheat stubble and 4 in. to fallow land during a period of 2 days. Run-off was 3.1, 27.6, and 23.2 percent, respectively, and soil erosion was at the rate of 0, 1.29, and 1.75 tons per acre in the same sequence.

Run-off from prairie and young alfalfa on Carrington silt loam with a 5° slope during a period of about 7 mo. was 3.8 and 19.2 percent, respectively, from a total rainfall of 10.6 in.

Four in. of water applied to each plat in spring when the alfalfa was 5 in. tall resulted in 5.9 percent run-off in prairie and 40.8 percent in alfalfa. No erosion occurred in the grassland, but 0.72 ton per acre in the field.

Run-off resulting from the application of 3 in. of water in 1.5 hr. on May 10 on a 7° slope on Lancaster sandy loam was nil from burned prairie, but 20 percent from broken prairie cropped to corn for a period of 6 yr. Topsoil lost by erosion was at the rate of 12.2 tons per acre.

A soil covered with its natural mantle of climax vegetation represents conditions most favorable to maximum absorption of rainfall and maximum erosion control.

Analysis and control of landslides, R. G. HENNES (*Wash. Engin. Expt. Sta. Bul. 91 (1936), pp. 57, figs. 17*).—The purpose of this bulletin is to develop, in outline, an applied science of landslide control. The approach to this goal consists of (1) investigation of the nature of the shearing strength of soil, (2) investigation of the load conditions which result in exceeding this strength, and (3) application of the theory to the practical problems of analysis and control.

Part 1 deals with friction and cohesion, part 2 with the computation of the stability of slopes, and part 3 with the actual occurrence of landslides. The principles thus developed are then applied to the selection of proper methods of control. A method for determining the proper spacing of piles is developed, and methods are suggested for the design of works for drainage of gravitational and of capillary water.

It is pointed out that the application of new methods to problems connected with landslides has become possible through the development of tests to measure the physical properties of soils. To a large extent the efficiency of landslide control must depend on the accuracy with which the properties of soil have been determined for the individual case.

Results of agronomic-hyrotechnical drainage experiments on clay soils [trans. title], H. FLODKVIST (*3. Internatl. Cong. Soil Sci., Oxford, Eng., 1935, Trans., vol. 3, pp. 164-168*).—The author briefly discusses the movement of water in drained soils and presents the bases of a theory, applicable within certain limiting conditions, with regard to transverse drainage.

On the determination of the drainage rate [trans. title], V. SETINSKI (*3. Internatl. Cong. Soil Sci., Oxford, Eng., 1935, Trans., vol. 3, pp. 163, 164, fig. 1*).—The author here presents, in abbreviated form, the development of an equation for the rate of drainage of a given volume of a soil.

Subsoil structure and crop nutrition, E. M. CROWTHER (*3. Internatl. Cong. Soil Sci., Oxford, Eng., 1935, Trans., vol. 3, pp. 126-139*).—The author "advances the hypothesis that some of the more deeply rooted farm crops in humid temperate climates utilize water, nitrates, and possibly other soluble nutrients stored through the winter in the lower horizons of loams and heavier soils, provided that these are well drained and have a well-expressed soil structure." As an illustrative example, he notes that "we have obtained in parallel experiments over 5 yr. four responses of potatoes to potassium at Rothamsted but none at Woburn, and, on the other hand, no responses of sugar beet at Rothamsted but two at Woburn. Before one can decide which soil is deficient in available potassium, one must bear in mind the rooting habits of the crop and the general nature of the subsoil." To obtain really satisfactory information "it is necessary to join the laboratory and field methods by studying the relationship of the roots to the physical and chemical composition of the lower horizons. Even though the difficulties of sampling subsoils are great, it may prove possible to study the changes in the surface soils under different

systems of rotation, cropping, and manuring and interpret these in terms of the general properties of the subsoil and the root ranges of the crops."

On the study of the fertility of the soils of the Belgian Congo [trans. title]. J. BAUYENS (3. *Internatl. Cong. Soil Sci., Oxford, Eng., 1935, Trans., vol. 3, pp. 129-131*).—The author defines as a growth factor any cause, physical, chemical, physiological, or climatic, capable of a favorable effect upon a given crop. Although these growth factors are numerous and not altogether known and a scale of fertility cannot be based upon any one, or even two or three, of these factors, the author believes the following to form an adequate basis for judging the fertility of a soil under consideration: (1) Mechanical composition of the soil, (2) the effectiveness of utilization of the soil water and atmospheric moisture, (3) the plant food resources (exchangeable bases and phosphate), (4) the biological analysis (under which are included micro-organisms, carbon dioxide production, nitrates, catalytic power, and content of organic matter and nitrogen), and (5) the general appearance of the profile. The use of these factors, taken together, as indexes of general soil fertility is discussed briefly.

The decomposition of lignin in plant materials, A. G. NORMAN (3. *Internatl. Cong. Soil Sci., Oxford, Eng., 1935, Trans., vol. 3, pp. 105-108*).—"The determination of lignin is affected by the presence of pentose units and proteins unless special precautions are taken. Determinations made on decomposing plant materials are apt to be misleading because pentose-containing hemicelluloses are being progressively removed and microbial protein concurrently synthesized. When these disturbing factors are taken into account, it may be shown that lignin under aerobic conditions is slowly but steadily fermented. In a sample of oat straw, at least 40 percent and probably over 50 percent of the lignin was removed in 12 mo."

Some physical factors controlling the accuracy in estimating the number of nitrogen-fixing bacteria in soil, H. W. BATCHELOR (3. *Internatl. Cong. Soil Sci., Oxford, Eng., 1935, Trans., vol. 3, pp. 113-117, figs. 4*).—This note, contributed from the Ohio Experiment Station, is concerned mainly with effects of the method of dispersion upon counts subsequently obtained. Figures concerning the rate of shaking and the time lapse between shaking and sampling are graphically presented.

"Although additional work should be conducted on this problem before any particular method is suggested as the one most nearly meeting the requirements for accurate studies on the populations of these organisms in soil, it is believed that the data indicate the need of carefully standardized procedures in any investigations involving the determination of the populations of the soil flora."

Nitrogen fixation by rice soils and rice plants, D. L. SAHASRABUDDHE (3. *Internatl. Cong. Soil Sci., Oxford, Eng., 1935, Trans., vol. 3, pp. 111-113*).—As one of the results of the investigation here concisely outlined, "it can . . . be safely stated that nitrogen-fixing inoculum is not carried within the rice seed, although it may be carried on the surface of the seed. On the other hand, it is certain that the inoculum is in the rice soil and may be carried along with the soil. The presence of the growing rice roots helps this inoculum in fixing larger quantities of nitrogen than the soil would otherwise fix because the rice roots form a good host."

Phosphate investigations in Montana, 1936 (*Montana Sta. Bul. 334* (1937), pp. 22, figs. 4).—This bulletin consists of two separate articles.

I. Tests with alfalfa and other farm crops, J. Green.—Phosphate fertilizers increased the yields of crops, especially those of alfalfa. Alfalfa fertilized with phosphate contained more moisture at harvest time than unfertilized

alfalfa. Phosphate-treated alfalfa showed increased yield and phosphorus content when the crop was grown in phosphorus-deficient soils.

"Phosphate fertilizer should, if possible, be placed at a depth in the soil where there is ample moisture. When rainfall is low phosphate placed near the surface is of little value in fertilizing the crop. The addition of a phosphate fertilizer does not improve crops that are badly injured by drought or grasshoppers. Alfalfa is a much greater user of phosphate than the grain crops."

II. *Phosphorus responses on potatoes*, F. M. Harrington and W. E. Polinger.—Phosphate-treated plants came up before those not treated, made a more rapid early growth, and showed a larger root development, together with an earlier and heavier set of tubers. Phosphate treatment usually improved both yield and grade.

Phosphate fertilizer mixtures: Chemical changes and physical effects induced in mixtures of triple superphosphate with dry and wetted limestone and dolomite, W. H. MacINTIRE, L. J. HARDIN, and F. D. OLDHAM (*Indus. and Engin. Chem.*, 28 (1936), No. 6, pp. 711-717, figs. 3).—At the Tennessee Experiment Station, "laboratory and field mixtures were studied to secure information for guidance in practice. Speed and extent of diphosphate transitions were computed from carbon dioxide evolutions in closed systems and from decreases in the water-soluble P_2O_5 content of larger piles." Prewetting of the limestone and dolomite was introduced "to accelerate reaction and to expedite the dry mechanical condition that characterizes maximal diphosphate transition and in particular to increase the content of readily available magnesia in the dolomite mixtures." The divergence between the mechanical effects of dry and wet admixtures and also between the effects of machine and hand mixing, the elimination of set-up by reworking the mixtures before storage, the conditions found in unconfined and in immediately bagged mixtures, and related factors were considered.

The role of elements other than nitrogen, phosphorus, and potassium in crop production, L. E. WRIGHT (*Sci. Agr.*, 17 (1937), No. 5, pp. 283-293).—From the review and experimental data presented it is concluded that a sufficient amount of boron in an available form in the soil is necessary for the healthy growth of mangels, turnips, and apples. Calcium, magnesium, sulfur, iron, manganese, copper, and zinc are also considered.

AGRICULTURAL BOTANY

[Report of the] division of plant biology, H. A. SPOEHR (*Carnegie Inst. Wash. Yearbook*, 35 (1935-36), pp. 195-230, fig. 1).—Progress reports are given on biochemical studies (including carotenoid pigments, the absorption of carbon dioxide by the unilluminated leaf, the amylolytic activity of leaves, and the chemistry of the cell walls in wood), by Spoehr, J. H. C. Smith, H. H. Strain, and H. W. Milner; investigations on the cambium and its derivative tissues, by I. W. Bailey; experimental taxonomy (including the principles and problems, the species problem, investigations on *Madinae*, transplant studies, and other investigations), by J. Clausen. D. D. Keck, and W. M. Hiesey; desert investigations (including field work, environmental conditions, and the behavior of desert plants), by F. Shreve. T. D. Mallery, and W. V. Turnage: ecology (including adaptation and origin, by F. E. Clements, F. L. Long, and E. V. Martin, and climate, climax, and succession, by F. E. and E. S. Clements); paleobotany, by R. W. Chaney; and climatological research (including fundamental studies, climatic influence in trees, cycle studies, and long chronologies), by A. E. Douglass.

Contributions to the electrophysiology of growth, M. G. KHOLODNIĬ (N. G. CHOLODNY) and E. Kh. ZANKEVICH (E. Ch. SANKEWITSCH) (*Zhur. Inst. Bot. Ukrain. Akad. Nauk* [Jour. Inst. Bot. Acad. Sci. Ukraine], 6 (1936), No. 15, pp. 105-124, figs. 3; Eng. abs., pp. 123, 124).—After a critical review of recent literature (12 titles) on the electrophysiology of growth, the authors report their experiments designed to check on the hypothesis that transportation of growth substance in the plant organs takes place through cataphoresis. Their results are believed to confirm the view that the electric current affects the transportation of hormones not directly as electrolytes but indirectly through the complex system of living protoplasm.

The absorption of electrolytes in large plant cells, W. J. V. OSTERHOUT (*Bot. Rev.*, 2 (1936), No. 6, pp. 283-315, figs. 4).—This review (with bibliography of 128 titles) considers the kinetics of penetration, accumulation, selective permeability, and the nature of the protoplasmic surface. It is stated that "the facts and principles here set forth are the results of investigations of large cells which offer special advantages for such studies. How far they are applicable to other cases remains to be seen. This brief outline indicates progress in dealing with some very interesting variables. It also gives a hint of the host of problems awaiting solution."

Water relations and osmotic pressures of plant cells, T. A. BENNET-CLARK, A. D. GREENWOOD, and J. W. BARKER (*New Phytol.*, 35 (1936), No. 4, pp. 277-291, figs. 3).—The so-called "osmotic value" of the cell sap as determined by the plasmolytic method was markedly greater than the osmotic pressure as determined by the cryoscopic method in roots of beet and swede and petioles of *Begonia*, but in petioles of *Caladium* and *Rheum* the results were equal. The former tissues thus showed a positive water secretion from the external medium into the vacuoles in addition to the inward flow due to the osmotic pressure of the cell sap. In *Caladium* and *Rheum* the flow of water was conditioned by the osmotic pressures only.

It is shown that the cells of tissues with active water-secreting powers should not be plasmolyzed by their own expressed sap, whereas juice from tissues not possessing water-secreting powers should plasmolyze about half of the cells of the tissue. This was demonstrated experimentally, thus confirming the conclusion that the osmotic pressure of the vacuole is not the sole force sending water into the cell (at any rate in potential growing tissues).

Electrophoresis trials in the interior of the plant cell [trans. title], A. GUILLERMOND and N. CHOUCROUX (*Compt. Rend. Acad. Sci. [Paris]*, 203 (1936), No. 3, pp. 225-229, figs. 2).—Using electrophoretic methods on cells of the epidermis of onion bulb scales, of the perianth of tulip flowers, of leaves, bracts, and flowers of *Iris* spp., and of leaves of *Blodea*, the author studied the effects of an electric field on the morphological constituents of the cell. No action of this field on the charged elements within the living cell was noted. This defense mechanism of living material, a property doubtless important for the maintenance of equilibrium, is believed to have been reported here for the first time.

An attempted theory of photosynthesis, J. FRANCK and K. F. HERZFELD (*Jour. Chem. Phys.*, 5 (1937), No. 4, pp. 237-251, figs. 3).—"An attempt is made to explain quantitatively many observations described in the literature on the photosynthetic production of oxygen in its dependence on light intensity, time of irradiation, etc. Four photochemical steps and two dark reactions are assumed in which, among others, a peracid, formic acid, and a peraldehyde occur. These are the same intermediate compounds as in auto-oxidation processes, so that the similarity between these two inverse processes is striking.

Light saturation is explained by back chain reactions initiated by photolytical decomposition of the percompounds. The agreement between observations and calculations is good. The picture gained for the photosynthesis of CO_2 can be applied in the same way for that of plant acids, but the plant acids can also be photo-oxidized in a reaction sensitized by chlorophyll."

The mechanism of utilization of radiant energy in the process of photosynthesis [trans. title], A. N. DANILOV (DANILOW) (*Trudy Bot. Inst. Akad. Nauk SSSR, Eksp. Bot. (Acta Inst. Bot. Acad. Sci. URSS, Bot. Expt.)*, 4. ser., No. 2 (1936), pp. 5-76, figs. 15; Ger. abs., p. 72).—On the basis of assimilation tests with blue-green, red, and green algae exposed to white and colored electric lights, it is concluded that both the quantitative and qualitative composition of the light and the reciprocal relations of the group of rays making up a light source all have great significance for the photosynthetic process. A bibliography of 85 titles is included.

About influence of potassium on the gaseous exchange and the accumulation of chlorophyll in buckwheat, V. A. BRILLIANT (*Trudy Bot. Inst. Akad. Nauk SSSR, Eksp. Bot. (Acta Inst. Bot. Acad. Sci. URSS, Bot. Expt.)*, 4. ser., No. 2 (1936), pp. 77-91, fig. 1; Eng. abs., pp. 89, 90).—The photosynthetic capacity of buckwheat was lowered most with excess potassium, in a smaller degree with traces, and still less with 2 mg per liter of culture solution. Respiration was increased with subnormal or excess amounts of potassium. The decrease in photosynthesis and increase in respiration were correlated with diminished dry matter when potassium was deficient or excessive, but no correlation could be detected between variations in gaseous exchange and diminishing dry weight. The chlorophyll content was somewhat lowered with potassium absent, it equaled that of the controls with 2 mg per liter of culture solution, and it was much lower in amount with excess potassium.

The influence of accumulation of carbohydrates in the leaf tissues on the energy of photosynthesis and respiration [trans. title], A. G. TOSHCHEVIKOVA (TOSTSCHEVIKOVA) (*Trudy Bot. Inst. Akad. Nauk SSSR, Eksp. Bot. (Acta Inst. Bot. Acad. Sci. URSS, Bot. Expt.)*, 4. ser., No. 2 (1936), pp. 93-111; Fr. abs., pp. 109, 110).—By the simultaneous processes of photosynthesis and direct absorption of sugars from solutions, maximum quantities of carbohydrates were obtained amounting to 42 percent of the dry weight in leaves of *Primula obconica* and 17 percent in those of *Hedera helix*. These results confirm the conclusion that leaves of different species accumulate different maximum amounts of plastic carbohydrates. The energy of respiration increased with an increase in the carbohydrate content of the leaves, and the maxima of the two processes were simultaneous. Photosynthesis also increased up to a certain limit, but when the accumulation of sugars and starch became very high the energy of photosynthesis diminished, and it became very feeble when their maximum amounts were reached.

The photoperiodism and the growth of the tea plant, V. N. POKROVSKIY (W. N. PORBOVSKY) and S. G. MERABIAN (*Sovet. Subtrop. (Soviet Subtrop.)*, No. 11 (27) (1936), pp. 37-55, figs. 7; Eng. abs., p. 55).—Acclimatized Chinese-Indian hybrids and the nonhardy Indian species were tested in western Georgia (1932-35) as to the influence of shortened daylight periods. By the use of suitable photoperiods the authors were able for the first time in the U. S. S. R. to obtain hybrids of the northern and southern forms.

The influence of day length in connection with artificial illumination of plants in winter [trans. title], J. W. M. ROODENBURG (*Ber. Deut. Bot. Gesell.*, 55 (1937), No. 1, pp. 5-32, pls. 5, fig. 1).—It is shown that with medium light intensities and times of illumination leaf development is proportional to the light

quantity (duration \times intensity). Thus the leaf develops in direct correlation with CO_2 assimilation. On the other hand the specific influence of day length is expressed in relation to induction of the flowering period, and, within wide limits, it stands in no relation to light intensity. Here the specific effect depends exclusively on the duration of daily illumination. From these and other experimental results with cucumbers and strawberries grown in the greenhouse, it is postulated that the lack of any relation at all with CO_2 assimilation and the very far-reaching agreement with the cell-stretching hormones render it probable that the length of the daily light period in one manner or another controls the growth conditions of the plant.

The action of light on the germination of light-arrested fruits of the Gramineae [trans. title], E. ZEHER (*Jahrb. Wiss. Bot.*, 83 (1936), No. 1, pp. 60-104, figs. 2).—This is a study of the germination relations of *Poa pratensis* and four species of *Bromus*, including the relations between the fat in the seed and the behavior of light and dark embryos toward light.

The action of radiation of specific wave-lengths in relation to the germination of light-sensitive lettuce seed, L. H. FLINT (*Compt. Rend. Assoc. Internatl. Essais Semences (Proc. Internatl. Seed Testing Assoc.)*, 8 (1936), No. 1, pp. 1-4, fig. 1).—Continuing this series of studies (E. S. R., 74, p. 638), the present work made use of specific wavelengths employing a large spectrum, a single-filament incandescent light source, a condenser lens, concentration of light on an adjustable slit, an achromatic lens, a prism, and a silvered mirror. The detailed results given make it apparent that some components of white light promote germination while others inhibit it. The net effect of white light on germination is thus indicated as associated with the dominance of either the promoting or the inhibiting influence. Hence, in those seeds whose germination is hindered by white light a relatively greater absorption of the radiation inhibiting germination is suggested. In light-sensitive lettuce seed the net effect of white light is to promote germination.

The wavelengths inhibiting and promoting germination are correlated, respectively, with those inducing bending of plants toward the light and those promoting carbon fixation. It is thus concluded that the study of seed germination may have an intimate and important bearing not only on the immediate problems relating to seeds, but also on a wide range of problems covering the activities of plants in general.

Stem and leaf anatomy as influenced by supplemental light, F. RAMALEY (*Colo. Univ. Studies*, 23 (1936), No. 3, pp. 245-250, figs. 24).—Of the 25 plant species from various families given full winter daylight exposure in the greenhouse, with additional illumination increasing the day length 4 hr. or more (using electric lamps furnishing 30 footcandles at the level of the plants), 15 showed no appreciable anatomical differences between plants given long- and short-day exposures. In some species, however, the experimental plants were slenderer than controls exposed only to winter daylight, the vascular tissue was greatly reduced, the vessels tended to be smaller, and the phloem elements were smaller and fewer in number. Starch was usually absent from the experimental plants. The leaves were less modified than the stems, although a general tendency existed for leaves of the treated plants to be thinner, with a looser spongy tissue. Roots of experimental plants were nearly always reduced, especially as to the vascular tissue.

Changes in the permeability of protoplasm and the dynamics of frost resistance of winter cereals in connection with their passage through the light stage, E. ŠESTÁKOV and L. I. SERGEEV (*Compt. Rend. (Dok.) Acad. Sci. U. R. S. S., n. ser.*, 4 (1936), No. 1, pp. 25-28, figs. 4).—The authors conclude

from this study that there is a negative correlation between the permeability of protoplasm (rate of exosmosis) and frost resistance in winter cereals, the higher the permeability the lower being the resistance to frost. The further the variety was advanced in its light stage, the higher was its permeability and the lower was its frost resistance. The 9-hr. day, at optimum temperature, retarded, but did not fully prevent, passage through the light stage. Correspondingly, when the plants were kept for 15 days on a 9-hr. day, the permeability of the protoplasm increased and frost resistance fell as compared with the controls.

Studies of the relation of temperature to water intake by plants, with special reference to transition reactions [trans. title], EL. ROUSCHEL (*Sitzber. Akad. Wiss. Wien, Math. Naturw. Kl.*, 144 (1935), I, No. 5-6, pp. 313-348, figs. 6).—This study deals principally with the water intake at constant root temperature, the transition reactions from warm to cold and the reverse, the reversibility of cold inhibition, and the reciprocal relations of absorption and transpiration.

The action of certain quinoline derivatives on the germination of wheat [trans. title], G. FÉON (*Ann. Épiphyt. et Phytogénét.*, n. ser., 2 (1936), No. 3, pp. 333-340, figs. 2).—Neutral sulfate of ortho-oxy-quinoline in suitable concentrations influenced favorably the early phases of development in wheat seedlings, and the author calls attention to the fact that these same dosages are also capable of completely inhibiting the development of certain plant parasites.

The dinitrobenzol method of determining the germinability without germination testing, II [trans. title], A. GÜREWITSCH (*Ber. Deut. Bot. Gesell.*, 55 (1937), No. 1, pp. 54-58).—This method of determining the germinability of seeds is said to depend on the reduction of ortho- and paradinitrobenzol rather than on that of metadinitrobenzol. It may also be used for determining small amounts of ortho- and paradinitrobenzol in metadinitrobenzol.

Effect of extracts from the corn plant on growth of excised root tips, W. J. ROBBINS and V. B. WHITE (*Bot. Gaz.*, 98 (1937), No. 3, pp. 520-534, figs. 5).—Milk from immature corn grains was injurious or without benefit to growth of excised corn root tips, the diffusate from germinated corn grains benefited their growth in agar medium containing dextrose and mineral salts, the agar diffusate from coleoptile tips slightly inhibited their growth when less than 1 mm long, and the diffusate from root tips slightly favored their growth. Aqueous extracts of the terminal portions of seedling roots favored growth of excised root tips in an agar medium containing dextrose. Extracts of germinated corn grains at the higher concentrations injured excised corn root tips, inducing hypertrophy of the cortical cells, while at lower concentrations they were beneficial. Replacing the nutrient solution with fresh solution when the growth rate of the excised root tips had decreased resulted in little or no benefit when a mineral nutrient containing dextrose was used, but caused renewed growth when the solution contained root or corn grain extracts or autolyzed yeast.

"The significance of the experiments from the standpoint of a medium suitable for the continued growth of excised corn root tips is discussed."

Mitochondria in the life cycles of certain higher plants, L. E. ANDERSON (*Amer. Jour. Bot.*, 23 (1936), No. 7, pp. 490-500, figs. 27).—In *Antirrhinum majus*, *Philadelphus coronarius*, and *Hyacinthus orientalis*, it was possible to demonstrate mitochondria (used to include plastid primordia) and plastids in structures in which they had not previously been reported by using fixatives on the basic side of pH 4.2-5.2. All living cells studied contained plastid primordia, the development of which could be traced in the stem growing point and in

the leaf cells. Subsequent organs developed from such growing points contain these primordia. They are present in microspore mother cells from which they are distributed about equally to the microspores, where they are particularly abundant. Transition into plastids was followed in both pollen grains and tubes. These inclusions are carried from the microspores into the pollen tube by the streaming cytoplasm, are particularly numerous about the male nuclei, and they persist at least until the pollen tube ruptures into the embryo sac. Megaspore mother cells contain mitochondria identical in appearance with those in the microspore mother cell, and they are also distributed equally to the four megaspores. The functional megaspore possesses mitochondria which are strikingly abundant around its nucleus, and the nucleus of each daughter cell is in turn surrounded by mitochondria. The egg cell contains both plastids and mitochondria, as do all cells of the embryo sac. The polar nuclei are surrounded by these inclusions both before and after they fuse.

In fertilization of *Antirrhinum*, the pollen tube does not rupture until some time after it has entered the embryo sac but remains for a time in contact with the egg. A protrusion is formed toward the egg, and at that point the tube ruptures. The male nucleus which fuses with the polar nuclei is surrounded by mitochondria, so that the resulting endosperm contains cytoplasmic inclusions from the male plant. The second male nucleus, surrounded by mitochondria, enters the egg and fuses with the egg nucleus. The membrane surrounding the egg, after puncture by the male nucleus, contains an opening large enough for mitochondria to pass in from the pollen tube. Plastids and their primordia are present in all cells of the developing embryo where the transitional stages between mitochondria and plastids are most abundant. These inclusions occur in the cytoplasm of all cells formed before the growing points appear and in the growing points themselves.

It is indicated that if mitochondria from the male cytoplasm enter the egg cell any defective cytoplasmic inclusions in the pollen tube would be transmitted to the egg. Explanations of maternal inheritance which assume that no cytoplasm is transferred from the male to the female plant in fertilization are thus inadequate. Several possibilities are presented.

Parthenocarpy induced by pollen extracts, F. G. GUSTAFSON (*Amer. Jour. Bot.*, 24 (1937), No. 2, pp. 102-107, figs. 3).—Chloroform extracts of pollen used to stimulate ovarian growth in a number of plants indicated that there exists in the pollen of some plants a chloroform-soluble material which initiates growth in the ovary and in some cases causes seedless fruits to be formed.

Studies on the bacterial-plant groups of cowpea, cicer, and dhaincha, I, II, M. S. RAJU (*Zentbl. Bakt. [etc.]*, 2. Abt., 94 (1936), Nos. 9-13, pp. 249-262; 14-18, pp. 337-348, figs. 5).—Two papers are presented.

I. Classification.—In this study at the University of Wisconsin, "some strains of nodule bacteria were isolated in pure cultures from the plants of cowpea, gram, and dhaincha groups. Based upon the variations in the cultural characters, three new types are recognizable among the nodule bacteria of the cowpea group. As a result of plant inoculation studies, black gram, cluster bean, cowpea, dew gram, groundnut, horse gram, green gram, indigo, lablab, pillipesara, red gram, sunn-hemp, and wild-indigo were found to belong to the cowpea bacterial-plant group. The cultures of lupine, dalea, soybean, and dhaincha groups are somewhat related to the cowpea group, though the cowpea organisms cannot produce nodules on the plants of these groups. Wide variations in the infective power of nodule bacteria of the cowpea group were observed on different varieties of host plants of the same group. Gram and dhaincha were found to be two new bacterial-plant groups. The cicer group

is entirely distinct from the other groups, while dhaincha is somewhat related to the cowpea group."

II. *Variations in the infective power of the nodule bacteria of cowpea group*—(1) *Influence of light on infection*.—In these studies at the University of Wisconsin, the infective power of a strain varied with the variety of the host. If the light under which the plants were grown was beyond a favorable range, the nodule formation by the weaker strains was inhibited. A heavy inoculum of a soil from India failed to infect some plants with nodule bacteria when the light was deficient. The ultraviolet rays and those of shorter wavelength filtered off by the greenhouse glass seemed to exert very little influence on the infective power of the bacteria. Some of the results indicated the possibility of selection of bacterial strains of higher infective power.

The influence of host plant species in relation to the effectiveness of the *Rhizobium* of clovers, T. H. STRONG (*Jour. Council Sci. and Indus. Res. [Austral.]*, 10 (1937), No. 1, pp. 12-16).—"Strains of the clover-nodule producing organism isolated from subterranean clover have proved effective in association with that plant and ineffective with red and white clover, and vice versa. The organisms freely invade all three hosts. This variation in effectiveness, which can be attributed to specific host plant reaction, is distinct from that displayed by strains effective or partially effective upon one particular host, a variation attributed to 'virulence.' . . . So far, no strains have proved highly effective upon all three host plants."

Studies of the metabolism of *Aspergillus niger*.—I, The influence of phytin on the metabolic processes of *A. niger* [trans. title], W. BRAUN and A. FREY (*Biochem. Ztschr.*, 285 (1936), No. 3-4, pp. 219-227).—Increases in the phosphorus content of the nutrient solution caused increases in mycelial weight and sugar consumption, but acid formation was less dependent on the amount of phosphorus present. When the nitrogen supply consisted in part of organic salts, acid production decreased with an increase in the phytin phosphorus supply. The sugar consumption and mycelial weight were influenced more by the form of phosphorus than by that of nitrogen supplied. The latter influenced especially the acid production. Most of the phytin not absorbed by the cells was split by phytase. Independently of the nitrogen supply, the phosphorus consumption was in all cases higher with the addition of phytin phosphorus than with that of inorganic phosphorus.

Nitrite and formaldehyde formation in certain algae, A. L. SOMMER (*Plant Physiol.*, 11 (1936), No. 4, pp. 853-861, figs. 4).—It was found by this study at the Alabama Experiment Station that light plays an important role in the reduction of nitrate to nitrite in the algal cell. Addition of phosphate to the nutrient accelerated this reduction and the formation of formaldehyde by certain algae. It is thought that nitrites combine with formaldehyde or an early condensation product thereof in the first step of protein synthesis. Protein synthesis and formaldehyde condensation to sugars may proceed simultaneously.

Tree injection, 1935 experiments.—A progress report, J. HEARMAN, B. F. GOODMAN LEVY and W. A. ROACH (*East Malling [Kent] Res. Sta. Ann. Rpt.*, 23 (1935), pp. 137-141, figs. 4).—Following injections of fertilizer solutions into apple trees (1935), leaf injury did not show itself immediately but only after an interval of three or more days after injection, so that sufficient fertilizer could be absorbed to cause serious damage before any warning was given. The delayed symptoms were apparently due to the leaves remaining in an "immature" condition for some weeks after expansion, a mature leaf being much more prone to such injury than an immature one. In the experiment

reported, the continued immature condition was probably due to a severe frost. It is concluded that leaf injury cannot always be relied upon as a warning that trees have absorbed sufficient fertilizer.

Variation in a species of *Fusarium* induced by high concentrations of zinc salts. A. W. DROCK (*Zentbl. Bakt. [etc.]*, 2, *Abt.*, 95 (1936), No. 13-17, pp. 341-347, figs. 3).—A single-spore strain of a *Fusarium* species was studied intensively at the University of California over a period of 2 yr. No variation or sectoring was observed in hundreds of single-spore and mass-transfer colonies of this strain on standard media, on media containing great excesses of neutral chlorides, sulfates, or nitrates, or on Coons' medium adjusted to high acidity. However, sectors frequently appeared when cultured on media containing high concentrations of zinc chloride, sulfate, or nitrate, and the evidence indicates that they were induced by the action of zinc on the nuclei or cytoplasm of cells of the parent mycelium. The parent and variant strains were shown by single-spore cultures to be pure and homocaryotic. A single spore of one of the variant strains gave rise to a further variant strain believed to be the result of an aberrant mitosis or a "spontaneous" gene mutation occurring during or shortly prior to the formation of the spore.

"It is suggested that the mechanism of action of the zinc ion lies either in an alteration of the self-perpetuating, extra-nuclear inclusions of the cytoplasm of the parent cells, or in an alteration of the genic constitution of the nucleus."

Toxicity of selenium to plants and animals. A. L. MARTIN (*Amer. Jour. Bot.*, 23 (1936), No. 7, pp. 471-483, figs. 5).—The toxicity to wheat and buckwheat plants was proportional to the concentration added as sodium selenite to soil or solution cultures. The effects varied from a decrease in growth rate with 1, 2, and 4 p. p. m. to extreme chlorosis and premature death with 8, 16, 32, and 64 p. p. m. The effectiveness of sulfur-selenium antagonism in solution cultures proved to be limited. A concentration of 1 p. p. m. could be rendered nontoxic by adding sulfate sulfur to the solution, but higher concentrations of selenium could not be rendered entirely nontoxic by sulfur. A sulfur-selenium ratio of 2.5:1 reduced selenium toxicity nearly as much as a ratio of 40:1. Buckwheat was more susceptible than wheat to selenium injury, and after sulfur additions there was greater residual toxicity to buckwheat. The amount absorbed by buckwheat from artificially selenized soil depended on the quantity applied, and the accumulation in the plant always exceeded the concentration in the soil.

Injury to rats resulted from diets containing ground stems, leaves, and seeds of seleniferous buckwheat grown in field cultures, the degree depending on the concentration in the plants. Small amounts stunted growth, while high concentrations were quickly lethal. Selenium proved more poisonous to the animals than to the plants. Buckwheat exhibiting no symptoms except for slight dwarfing contained enough poison, even when diluted with an equal part of a grain diet, to cause death in rats within 9 weeks.

Soil analyses of artificially selenized field cultures at the beginning and end of a 13-mo. interval indicated that moderate rainfall and cropping had very little effect in reducing the selenium content.

Distribution and ecology of plants significant to wild waterfowl in their breeding grounds in northern Iowa. A. HAYDEN (*Iowa Sta. Rpt.* 1936, pt. 1, pp. 105, 106).—This is a progress report.

On the influence of various liquid fixatives on stomatal behaviour: A critical contribution to the theory of Lloyd's alcohol fixation method. M. NADEL (*Palestine Jour. Bot. and Hort. Sci.*, 1 (1935), No. 1, pp. 22-42, figs. 3).—

Tests with a considerable number of fixatives indicated that none fixed the stomata so that the state of the opening at the time of fixation was truly preserved. The results led to the hypothesis that the varying action of the same fixative on the stomatal mechanism of different species is to be explained on the basis of differences in the structure of the stomatal membranes. It is believed that the arrangement and relative amounts of layers composed of such chemical substances as cutin, cellulose, etc., in the stomatal membranes cause differences in the amount of swelling, inducing opening of the stomata in some cases and closing in others. It is considered even possible that these physical movements may play a certain role in the movements of stomata in vivo. A bibliography of 28 titles is included.

A simple gas analysis apparatus for the measurement of plant respiration, B. N. SINGH and P. B. MATHUR (*Plant Physiol.*, 11 (1936), No. 4, pp. 881-883, figs. 2).—"The principle of the apparatus consists, in brief, in measuring the pressures exercised by the various constituents of a gaseous mixture. As the partial pressure of a component is proportional to its concentration in the gaseous sample and the sum of the various partial pressures is equal to the total pressure exerted by the gas sample, the percentage content of the component, say x , is easily calculated: $x = h \times 100/H_0$, where h = the partial pressure of the component under consideration, and H_0 = atmospheric pressure in mm Hg."

GENETICS

Cytological phenomena connected with self-sterility in the flowering plants, E. R. SEARS (*Genetics*, 22 (1937), No. 1, pp. 130-181, pls. 2, figs. 4).—In this contribution by the U. S. Department of Agriculture and the Missouri Experiment Station, it is stated that "self-sterility in all higher plants thus far investigated bears interpretation on the basis of a reaction of the immune type between the male gametophyte and diploid female tissue. Differences in behavior of the male gametophyte depend on localization of this reaction in different parts of the pistil.

"The present investigation permits the following classification according to when the incompatibility reaction occurs: (1) Before the pollen germinates, (2) while the pollen tube is growing in the style, and (3) when the tube reaches the ovule." Group 1 (*Brassica oleracea italica*, *Raphanus sativus*, *Pelargonium hortorum*, and *Secale cereale*) represents a tendency toward localization of the incompatibility reaction in the stigma, accompanied by a lack of the stigmatic fluid. In group 2 (*Petunia violacea*, *Abutilon hybridum*, *Nicotiana glauca*, *Linaria reticulata*, *Nemesia strumosa*, and *Tolmiea menziesii*), the reaction occurs in the stigma or in various parts of the style. In group 3 (*Gasteria*), the integuments of the ovule are concerned in the reaction, which prevents the incompatible tube from stimulating them to development.

"The following general conclusions may be drawn: (1) Self-incompatibility of the *Gasteria* type is rare in the plant kingdom, (2) incompatible pollen of crucifers tends to be inhibited on the stigma, (3) self-sterility in animals has a physiological basis similar to that in the higher plants, and (4) self-sterility in fungi perhaps depends on a reaction of the same immune type as assumed for animals and the higher plants."

A bibliography is provided.

Maternal inheritance in barley, D. W. ROBERTSON (*Genetics*, 22 (1937), No. 1, pp. 104-113, figs. 6).—The occurrence of maternal inheritance in a chlorina (solid color) plant obtained from Coast barley (*Hordeum vulgare*) is described from studies at the Colorado Experiment Station. See also earlier notes (El. S. R., 69, p. 344).

Coast V is a pale green chlorophyll-deficient plant, the chlorina color being the absinth green of Ridgway (E. S. R., 29, p. 762). When Coast V was used as a female parent in crosses with other barleys the F_1 , F_2 , and F_3 were all chlorophyll deficient like Coast V, indicating maternal inheritance of the chlorina plant color. In crosses in which Coast V served as the male parent the F_1 was normal green. In later generations the Coast V chlorina color did not appear or segregate out when Coast V was used as the male parent, indicating that the pollen does not carry a factor for Coast V chlorina. Factor pairs located in all seven linkage groups gave simple Mendelian segregations in both chlorina (Coast V) and normal green families (reciprocal crosses). Three generations of backcrossing to normal green did not change the Coast V parental color. Inoculation with extracts from Coast V chlorina seedlings had no apparent effect on the color of normal plants. Pedigree breeding showed Coast V chlorina to be constant for eight generations.

The effect of varying gene dosage on aleurone colour in maize, M. M. RHOADES (*Jour. Genet.*, 33 (1936), No. 3, pp. 347-354, fig. 1).—A new dominant gene Dt , according to Iowa Experiment Station studies in cooperation with the U. S. Department of Agriculture, interacts with recessive a_1 in the presence of the dominant allele of the other factors concerned with aleurone color of corn to give colored dots scattered over the aleurone layer. Dt is specific in its interaction with recessive a_1 . The effect on the dotted character of varying the dosage of recessive a_1 was additive and of varying the dosage of the Dt gene was nonadditive.

Note on the origin of triploidy in maize, M. M. RHOADES (*Jour. Genet.*, 33 (1936), No. 3, pp. 355-357).—In further cooperative studies, while triploid individuals in corn usually have occurred through fertilization of diploid or unreduced eggs by haploid sperm the case of triploidy described is shown to have arisen when the diploid number of chromosomes was contributed by the male parent.

Effect of luteus genes on longevity of seed in maize, M. G. WEISS and J. B. WENTZ (*Jour. Amer. Soc. Agron.*, 29 (1937), No. 1, pp. 63-75).—Two genes in corn, both located on chromosome 10, were found at the Iowa Experiment Station to be associated closely with longevity of seed. There was evidence that the viability of seeds homozygous for the luteus₂ and luteus₄ genes was definitely decreased during dormancy. Progenies segregating about 25 percent of luteus seedlings soon after harvest dropped to about 1 percent of luteus seedlings after 2 yr. of dormancy. No decrease in viability of seeds homozygous for luteus₁, luteus₃, luteus₅, or luteus₆ was observed. Seedlings from old seeds homozygous for the luteus₂ and luteus₄ genes were also reduced greatly in vigor.

Further studies of mutations of the Porto Rico sweet potato, J. C. MILLER (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 460-465, figs. 2).—Four mutants derived from the Porto Rico variety are compared with the parent in studies at the Louisiana Experiment Station, as to characteristics, chemical composition, and yield. A mutant induced by X-ray treatment resembled one of the natural mutants.

Inheritance studies of several qualitative and quantitative characters in spring wheat crosses between varieties relatively susceptible and resistant to drought, J. H. TORRIE (*Canad. Jour. Res.*, 14 (1936), No. 10, Sect. C, pp. 368-385, fig. 1).—In genetic studies at the University of Alberta made in the F_2 and F_3 of three wheat crosses, glume color was found to be controlled by either one or two factor pairs in Selection I-28-60 × Milturum, and by two factor pairs in Reward × Caesium and Caesium × Marquis. Awning, straw color,

glume pubescence, and spike regularity were each governed by one factor pair, while three factor pairs were operative in the inheritance of seed color.

Polymeric factors seemed to control inheritance of straw strength, plant height, earliness, and grain yield. A partial dominance of strong straw and earliness was found in Reward \times Caesium and Caesium \times Marquis. Tallness and low grain yield were partially dominant in Reward \times Caesium. Evidence for transgressive segregation of earliness was obtained in Caesium \times Marquis.

Glume color, awning, straw color, glume pubescence, and spike regularity were inherited independently: white straw color and earliness were definitely associated in Reward \times Caesium and Caesium \times Marquis; and straw color and plant height were loosely linked in Caesium \times Marquis. Grain yield was not correlated significantly with straw strength, plant height, or earliness in Reward \times Caesium. Small but significant relationships were found among straw strength, plant height, and earliness in Reward \times Caesium and Caesium \times Marquis. In the F_4 of Reward \times Caesium a strong positive correlation was obtained between heading and maturity.

The genetics of resistance to bunt (*Tilletia tritici*, race 5 M. A.) in the cross Barletta \times Florence (Cheg 27-10x) [trans. title], R. NIEVES (*Physis*, 12 (1936), No. 41, pp. 51-63).—This gives a general review, followed by the author's genetic analysis of the factors for bunt resistance in the wheat cross Barletta \times Florence varieties.

Bud mutations in horticultural crops, A. D. SHAMEL and C. S. POMEROY (*Jour. Heredity*, 27 (1936), No. 12, pp. 486-494, figs. 2).—This is a summary of information which the authors have compiled regarding bud mutations in fruit and potato varieties. A partial bibliography is appended.

The physiological consequences of polyploidy, I, II, A. C. FABERGÉ (*Jour. Genet.*, 33 (1936), No. 3, pp. 365-399, figs. 2).—This study, conducted at the John Innes Horticultural Institution, is presented in two parts.

The first, growth and size in the tomato (pp. 365-382), presents evidence that tetraploids do not differ consistently from diploids in the total amount of substance produced. Although tetraploid embryos were about 30 percent heavier than diploids, this advantage was lost during the 11 days following the sowing of the seed. The tetraploids did not differ significantly from diploids in their water content.

The second paper, the effect of polyploidy on variability in the tomato (pp. 383-397), presents evidence that polyploidy results consistently in diminished variability. It is assumed that doubling of the number of genes results in an increased probability of the action of quantitative factors which is reflected in a greater physiological stability of the early meristems. The fact that tetraploidy results in diminished fruit size was confirmed.

An appendix, heterogeneity of a set of variances, by W. L. STEVENS, (pp. 398, 399), is included.

Reduction division, pollen lethality, and polyploidy in apples, O. HEILBOERN (*Acta Horti Bergiani [Uppsala]*, 11 (1935), No. 7, pp. 129-184, figs. 10).—Observations on 181 apple varieties showed 148 to be diploids and 33 triploids. In general, the diploids yielded good pollen and the triploids inferior pollen. The author suggests that the triploid apples are secondary autotriploids. A strong correlation was observed between triploid chromosomes and keeping quality. In a collection of 65 apple varieties all 12 triploids were good winter keepers, leading to the conclusion that autotriploidy exerts an influence on keeping quality. A factorial explanation, based on recessive pollen lethals, is offered for pollen abortion in diploid apples.

New filbert hybrids. C. A. REED (*Jour. Heredity*, 27 (1936), No. 11, pp. 427-431, figs. 2).—Discussing the general status of filbert breeding in the United States and describing some of the newer hybrids developed by various breeders, the author reviews briefly filbert breeding operations conducted by the U. S. Department of Agriculture. Seedlings obtained from crosses of foreign and American forms of *Corylus* showed greater hardiness than did the tender parents. The foliage almost invariably resembled that of the foreign parents, and the nuts in size, form, color, thinness of shell, and appearance of the kernel also favored the tender parent. Crosses in which *C. colurna* L. was used as the pollen parent yielded few viable seed, and the resulting seedlings yielded nuts which were for the most part without kernels.

The position of genetic investigations with cattle [trans. title], C. von PAROW (*Züchtungskunde*, 11 (1936), No. 9, pp. 343-355).—A brief popular review is given of present knowledge about the inheritance of color and markings, morphological characteristics, milk, butterfat, and meat production, lethal factors, and other characters in cattle.

Congenital hairlessness in calves of the black-spotted lowland breed as determined by lethal factors [trans. title], F. EISELE (*Züchtungskunde*, 11 (1936), No. 11, pp. 432-437).—Among 25 calves with different dams and sired by the same bull, 5 were hairless. Histological study of the hide showed a thickened epidermis with the absence of sweat glands. The hairless calves were produced by cows having the same sire when mated to a half-brother of their sire. There was also other inbreeding in the pedigrees. The condition was considered due to the operation of a single pair of recessive genes.

Syndactyly in swine and further results on the inheritance of color in swine [trans. title], C. KOSWIG and H. P. OSSENT (*Züchter*, 8 (1936), No. 12, pp. 324-329, figs. 5).—F₁ and backcross data are presented to confirm the inheritance of syndactyly in swine as due to the operation of a single dominant gene. An explanation of certain modifying factors in color inheritance is also presented.

A study of mutations in evolution.—III, The evolution of the equine foot, R. C. ROBB (*Jour. Genet.*, 33 (1936), No. 2, pp. 267-273, figs. 2).—Continuing this series (*Id.* S. R., 74, p. 325), measurements of one fore- and one hind-foot of 19 prehistoric and modern one-, three-, and four-toed horses suggested that the evolution from 4 to 3 toes was continuous, but that from 3 to 1 toe was discontinuous and required the intervention of a specific form mutation.

Inheritance of tail tip pigmentation in the house mouse. H. GRÜNEBERG (*Jour. Genet.*, 33 (1936), No. 2, pp. 343-345).—The inheritance of tail tip pigmentation was studied in the house mouse by crossing two strains, one of which had dark tail tip and the other of which had pink tail tips in about 73 percent of the animals. Of the 27 F₁s, 26 had dark tails and 1 a white tip. The backcross and F₂ populations suggested that the character was due to a single gene difference with dark tail dominant but not completely so.

An inherited tremor in *Peromyscus*. R. R. HUESTIS and E. BARO (*Jour. Heredity*, 27 (1936), No. 11, pp. 436-438, fig. 1).—A trembling condition associated with small size and heavy early mortality is described in the deer mouse. No affected animals produced young, but among the young produced by carriers there were 55 without tremors and 12 with tremors. This suggested a single pair of Mendelian factors responsible for the tremor character. The heavy mortality before trembling is exhibited in the young at over two weeks of age presumably accounted for the deficiency of the tremor class.

Studies on the creeper fowl.—X, A study of the mode of action of a lethal factor by explantation methods, P. R. DAVID (*Arch. Entwickl. Mech. Organ.*, 155 (1936), No. 3, pp. 521–551, figs. 6; *Ger. abs.*, pp. 548, 549).—Continuing this series from the [Connecticut] Storrs Experiment Station (E. S. R., 73, p. 458), study was made of the lethal mechanism of the creeper gene by comparing the behavior of tissues from homozygous creeper and normal birds in culture. Fragments of heart tissue from *CpCp* embryos were markedly inferior in their growth rate to similar fragments from normal embryos. The difference in the growth of other tissues from normal and creeper embryos was much less, if not negligible. Tissues from retarded non-*CpCp* embryos behaved in tissue culture much as tissue from *CpCp* embryos. In experiments in which tissues from 72- to 82-hr. embryos were grafted on the chorio-allantoic membranes of 8- to 9-day embryos, the fragments from the abnormal embryos evidently had the same capacity to survive and grow as those from the normal embryos except in the case of the limb cartilage. It is concluded that the death of homozygous creeper embryos before hatching is probably due to the dislocation of normal morphogenetic correlations on account of the disproportionate reaction of different developmental processes to the general retardation.

Genetical differences in eight-week weight and feathering, R. G. JAAP and L. MORRIS (*Poultry Sci.*, 16 (1937), No. 1, pp. 44–48).—Data are presented on the degree of feathering and weights at 8 weeks of age of birds hatched at the Oklahoma Experiment Station in the spring of 1936. The data differed from the findings of Schnetzler (E. S. R., 76, p. 464), Asmundson and Lerner (E. S. R., 70, p. 462), and others by showing that the 8-week weight of White Leghorns was greater than that of Barred and White Plymouth Rocks but less than that of Buff Orpingtons, White Wyandottes, and Rhode Island Reds. These results indicate that the first 8 weeks' growth is not necessarily associated with mature weight.

A statistical analysis of the total variance in 8-week weights indicated that 13 percent might be attributed to variety, 19 percent to sire, 27 percent to dam, and 23 percent to sex, with the residual of 18 percent due to several other conditions. Feathering was related to the 8-week weight, but 49 percent of the variance was not heritable. By selecting poorly feathered animals, strains of poor feathering were produced in Rhode Island Reds but selection for rapid feathering was less effective. Crosses of White Rocks and Buff Orpingtons increased the 8-week weight to that of the more rapidly growing parents.

The basis for differences in body size in fowls [trans. title], L. KAUFMAN (*Arch. Geflügelk.*, 10 (1936), No. 10, pp. 374–377; *Eng. abs.*, p. 377).—Study of the embryonic development of Bantam eggs in comparison with the eggs of normal fowls and crosses between them showed that the early development was the same, but by 11 days of incubation, size differences in the embryos were evident even though the eggs were of the same size. Bantam embryos hatched about one day earlier.

Development of fertility in young Barred Plymouth Rock males, R. L. HOGUE and E. E. SCHNETZLER (*Poultry Sci.*, 16 (1937), No. 1, pp. 62–67, figs. 8).—In studying the age at which young Barred Plymouth Rock cockerels attained sexual maturity at the Indiana Experiment Station, birds were sacrificed at 2-week intervals up to 20 weeks of age. Histological study showed the presence of mature sperm in the testes at 20 weeks of age. In individual matings with mature hens, some cockerels could fertilize the eggs at 16 weeks of age although others did not produce fertile eggs until 32 weeks of age. In pen matings, the age at producing fertile eggs varied from 21 to 30 weeks,

The early determination of pregnancy by the blood and urine of domestic animals [trans. title], D. KÜST (Züchtungskunde, 11 (1936), No. 11, pp. 417-422).—Biological tests for pregnancy give positive results sufficiently early to be useful only in the human (urine) and the mare (serum).

The cells of the adrenal cortex of the ewe during the estrual cycle and pregnancy, L. J. NAHM and F. F. MCKENZIE (*Missouri Sta. Res. Bul.* 251 (1937), pp. 20, figs. 13).—Study is reported of the changes in the histology of the adrenals occurring during oestrus and pregnancy in the ewe. Based on observation of the adrenal cortex from 49 ewes, an increase in the percentage of dark-type cells associated with increased amounts of lipoids was noted in early oestrus and early and late pregnancy. The fluctuating number of chondriosomes suggested their transitory nature and association with the production of secretion and other reserve material.

Influence of suckling upon galactin content of the rat pituitary, R. P. IERCE and C. W. TURNER (*Soc. Expt. Biol. and Med. Proc.*, 35 (1936), No. 3, pp. 367, 368).—Assays at the Missouri Experiment Station of the pituitary glands of lactating female rats showed that those not permitted to suckle young for 15 hr. had a much higher galactin content, 9.20 bird units, than those which suckled young during the last 3 hr. of the 15-hr. period, 3.06 bird units. Evidently the removal of milk from the mammary gland stimulates the removal of galactin from the hypophysis.

The adrenotropic principle of the pituitary in relation to lactation, E. T. GOMEZ and C. W. TURNER (*Soc. Expt. Biol. and Med. Proc.*, 36 (1937), No. 1, pp. 78-80).—In experiments with guinea pigs at the Missouri Experiment Station in continuation of the studies noted above, lactation was initiated in males and females even following the removal of the hypophysis by the administration of galactin and the adreno-cortico-tropic hormone extract from sheep pituitary, and lactation was maintained in lactating guinea pigs from 8 to 15 days following hypophysectomy. It is considered that the lactogenic, adrenotropic, and probably the carbohydrate metabolism hormones of the pituitary are necessary for continued lactation.

Initiation and maintenance of lactation in hypophysectomized guinea pigs, E. T. GOMEZ and C. W. TURNER (*Soc. Expt. Biol. and Med. Proc.*, 35 (1936), No. 3, pp. 365-367).—In studies at the Missouri Experiment Station, it was found possible to initiate lactation in hypophysectomized guinea pigs by the administration of lactogenic hormone and adrenal cortical hormone with glucose. However, under these conditions involution of the mammary gland was only slightly, if at all, prevented.

Heterogony of the glutathione content of new-born rabbits, I. M. LERNER, P. W. GREGORY, and H. GOSS (*Soc. Expt. Biol. and Med. Proc.*, 35 (1936), No. 2, pp. 283-285).—Further statistical analysis of the data of Gregory et al. on the relation of glutathione content of newborn rabbits to adult weight (E. S. R., 76, p. 322) led to the conclusion that each breed has its characteristic glutathione content as well as a characteristic rate of change in this factor correlated with adult size.

Time factor relationship of follicle stimulation and luteinization in the immature rat, R. T. FRANK and U. J. SALMON (*Soc. Expt. Biol. and Med. Proc.*, 35 (1936), No. 3, pp. 493-495).—Studies were made of the rapidity of response of the ovaries of immature rats to four injections of castrate urine, whole pregnancy urine, and extracts of the anterior hypophysis (maturity factor) and anterior lobe hormone. The rats' ovaries were examined at operation or autopsy from 26 to 144 hr. after the first injection. It appears that some ovaries respond as early as 26 hr. to gonadotropic hormone with a follicle-

stimulating reaction which becomes progressively more pronounced up to 64 to 72 hr. This is followed by luteinization reaching a maximum at 96 hr. Luteinization is influenced by the method of extraction, the quantity of extract administered, and the time after injection.

The collection of spermatozoa from the domestic fowl and turkey, W. H. BURBOWS and J. P. QUINN (*Poultry Sci.*, 16 (1937), No. 1, pp. 19-24, figs. 4).—Modifications in the method (E. S. R., 73, p. 671) for collecting semen from the domestic fowl are suggested which permit collections from turkeys and less responsive male fowls with greater ease of stimulation, less soiling of the material obtained, and milking semen from the ducts. Twenty-two birds yielded 2,372 cc of semen from November 8 to June 1.

FIELD CROPS

[Field crops work in Delaware], G. L. SCHUSTER and C. E. PHILLIPS (*Delaware Sta. Bul.* 205 (1936), pp. 14-18).—Fertilizer and breeding experiments with wheat, pasture improvement, fertility rotation experiments, and trials of barley varieties are reported on briefly.

[Farm crops investigations in Iowa], F. S. WILKINS, H. D. HUGHES, P. E. BROWN, L. C. BURNETT, J. B. WENTZ, C. Y. CANNON, J. L. ROBINSON, E. V. COLLINS, J. N. MARTIN, E. L. ERICKSON, H. C. MURPHY, P. M. NELSON, J. L. BOATMAN, L. W. FORMAN, R. H. WALKER, R. H. PORTER, E. O. BROWN, W. J. HENDERSON, C. S. REDDY, I. E. MELHUS, W. F. BUCHHOLTZ, C. M. NAGEL, A. L. BAKKE, W. E. LOOMIS, W. G. GAESSLER, A. T. ERWIN, E. S. HABER, N. D. MORGAN, H. GILSE, R. M. HIXON, C. K. SHEED, J. B. DAVIDSON, G. N. DAVIS, M. M. RHOADES, A. A. BRYAN, R. W. JUGENHEIMER, J. C. ELDRIDGE, E. W. LINDSTROM, and J. M. AIKMAN (*Iowa Sta. Rpt.* 1936, pts. 1, pp. 51-61, 62, 63, 104, 105, 108, 110, 111, 112, 113, 168, 169, 171, 172, 174, fig. 1; 2, pp. 24-35, 35-37, 38-41, 42-44, 49, figs. 6).—Progress (E. S. R., 75, p. 35) is again reviewed briefly in part 1 for breeding work with oats, barley, wheat, soybeans, sugar beets, potatoes, and sweetpotatoes; variety tests with oats, wheat, barley, alfalfa, red clover (strains), sweetclover, sugar beets, soybeans, edible soybeans, sweetpotatoes, and sorgho; trials of legumes and grasses for hay and pasture; variety-cultural experiments with oats and wheat; cultural studies with reed canary grass, sugar beets, and with alfalfa on bacterial wilt-infected soil; fertilizer and green manure tests for sweetpotatoes; the effect on alfalfa of spring-burning natural mulch material; cytology and physiology of winter hardiness in biennial white sweetclover and alfalfa; effect of cutting red and alsike clovers at different times; technic for determining water content of green forage; trials of legumes for green manure; tests of commercial cultures for the inoculation of legumes and nonlegumes; varietal and fertilizer factors affecting the storage quality of sweetpotatoes; studies of sugar production in sugar beets; propagation tests with sweetpotatoes; permanent pasture improvement; effects of fertilizing materials and methods of grazing on soil conditions and plant growth on permanent pastures; study of seed coat structure and environmental factors affecting germination of weed seeds; investigations of impermeability, longevity, dormancy, viability, and germination of seeds; eradication of biennial sweetclover by cultivation; properties and herbicidal action of furfural and its emulsions and of sodium chlorate mixtures; physiology and life history of European bindweed; and storage and translocation in dandelions.

Investigations proceeding as projects under the Iowa Corn Research Institute, covered in part 2, dealt with genetic relations of inbred lines; genetic studies; improving inbred lines by crossing followed by selfing and sibbing;

comparison of inbred lines obtained from open-pollinated varieties and from F_1 crosses between inbred lines; improvement through the use of inbred lines; kernel characteristics of seed corn in relation to yield; growth response of corn hybrids and varieties on soils of different levels of fertility and on various soil types; relation of time of planting to yield and quality of product among crosses between inbred lines of corn; the measurement of limiting environmental factors in the growth of the plant at different rates and spacings; correlation between composition and strength of stalk; comparative study of the stem and root development of some of the varieties of field corn grown in Iowa; trials of planting methods; tests of varieties, strains, and hybrid combinations in different parts of Iowa; curing and storage studies; the relation of grades of whole and shredded corn fodder and stover to methods of curing, storing, and baling; maintenance of pure seed sources of improved varieties through field inspection and certification; the production and distribution of seed of corn hybrids and of the parents from which they are derived; and breeding and cultural studies with popcorn. Other activities reported on as related to corn production included seed increase of new or improved varieties of field crops; technics used in seed analysis; methods of destroying localized areas of noxious weeds, particularly European bindweed and leafy spurge; physiology of field bindweed (*Convolvulus arvensis* L.) and other noxious weeds; and weed control in growing corn.

Several of the projects were in cooperation with the U. S. Department of Agriculture.

Biennial report of the Northeast Louisiana Experiment Station, St. Joseph, Louisiana, 1935-1936, C. B. HADDOX (*Louisiana Sta., Northeast Louisiana Sta. Bien. Rpt. 1935-36, pp. 12*).—Field crops experiments reported on comprised variety tests, fertilizer experiments, including carriers of nitrogen and potassium and rates of mixed fertilizer, production after different legume winter cover crops and after vetch turned under on several dates, yields following corn and soybeans, and spacing tests, all with cotton; and variety and spacing tests and comparisons of nitrogen sources for top dressing, all with corn.

[Crops experiments at the North Louisiana Substation], S. STEWART and R. E. WRIGHT (*Louisiana Sta., North Louisiana Sta. Bien. Rpt. 1935-36, pp. 2-16, 17, 18, 19, 20*).—Average results are again reported from experiments during several years with field crops at Calhoun (E. S. R., 75, p. 474), including variety tests with cotton, corn, oats, cowpeas, soybeans, crotalaria, sugarcane for sirup, grain sorghum, potatoes, and sweetpotatoes; fertilizer trials with cotton, corn, oats, potatoes, and sweetpotatoes; seedbed preparation and planting tests with cotton and corn; comparisons of winter cover crops for cotton and corn; corn variously spaced and interplanted with soybeans; grazing, spacing and cost of production for dairy feed tests with sweetpotatoes; a manured and fertilized rotation; and a production test with alfalfa.

[Field crops experiments in New Mexico] (*New Mexico Sta. Rpt. 1936, pp. 17-34, 36, 37, 38, 39, 40, 44, 45, 55, 58, 59, 62, 63*).—Agronomic research (E. S. R., 75, p. 36), reported on briefly from the station and from outlying fields, included variety tests with winter- and spring-sown wheat, oats, and barley, corn, grain sorghum, sorgo, millet, cotton, potatoes, sugar beets, alfalfa, soybeans, cowpeas, beans, and miscellaneous forage crops; breeding work with cotton and pinto beans; cultural (including planting) tests with hegari, sesbania, and sweetpotatoes; fertilizer experiments with cotton and potatoes; seed treatment and irrigation tests with cotton; studies of the annual production of sugar beet seed, concerned principally with effects of preceding crops, plant-

ing methods, and application of various fertilizers and manure; studies of varietal resistance to the curly top disease of sugar beets; determination of the grades and staple of New Mexico cotton; studies of the revegetation of southwestern ranges by controlled grazing, utilization of run-off water, and reseeding; and control of Johnson grass by cultural methods, chlorates, and burning. Certain lines of work were in cooperation with the U. S. Department of Agriculture.

[Field crop investigations at the United States Dry-Land Field Station, Ardmore, S. Dak., 1911-32], O. R. MATHEWS and V. I. CLARK (*U. S. Dept. Agr. Circ. 421* (1937), pp. 4-38).—The agronomic research reported, with suggestions for farm practice, supplemented that described earlier for 1912-25 (*E. S. R.*, 58, p. 324). The relative merits of summer fallow and other crop production methods also have been reported (*E. S. R.*, 67, p. 124). Experiments on crop rotations and cultural methods included comparisons of spring and fall plowing, subsolling, and listing for seven crops and their yields under alternate fallow and crop v. continuous culture; methods of preparing cornland and disking v. plowing grain stubble for small grains; yields of small grain, corn, and sorgo in different sequences; effects of sod crops on yields of succeeding crops; and crop yields on manured v. unmanured fallow and on fallow v. following green manure. Field scale trials compared field yields v. average yields from rotations; corn v. sorgo as preparations for wheat and oats; and crop yields in the 4-yr. rotation of sorgo, corn, oats, and manured fallow. Other activities included variety tests with common and durum spring wheat, oats, barley, corn for grain and silage, millet, sorgo, and alfalfa; Dakota Amber sorgo and Sudan grass in 7-in. drills v. 42-in. rows; and production tests with brome grass and crested wheat grass.

Biochemical distinctions between barley varieties, J. A. SHELLENBERGER and C. H. BAILEY (*Cereal Chem.*, 13 (1936), No. 6, pp. 631-655, figs. 5).—For this study by the Minnesota Experiment Station, samples of the same barley varieties were obtained from the University Farm at St. Paul for the years 1933, 1934, and 1935, and from the Crookston Substation for 1934. For a normal steeping period of about 50 hr. the variations in imbibition rates for the different varieties were small (detailed data given). The acrospire growth and diastatic activity were also compared. The diastatic activity of barley and malt was correlated when measured by the Lintner method but not by the Blish-Sandstedt method, and there was no correlation between the results of the two methods when applied to either malt or barley samples. Measured by the second method, Velvet was consistently high and Peatland low in diastatic activity, but with the Lintner method no such varietal differences were noted. Malting and drying increased the resistance of starch to taka-diastase action. There was a significant negative correlation between the diastatic activity (Blish-Sandstedt method) and starch resistance for barley, but a positive correlation existed between the Blish-Sandstedt values for green and dry malt and starch resistance. No varietal differences were found in starch resistance of barleys to enzymic action. Trebi barley was decidedly deficient in liquefying power, but on germination this became normal. The liquefying power of malt was not appreciably changed by drying, but the saccharifying power was increased. The liquefying action of barley could not be correlated with the saccharifying action of the same barleys (Lintner method).

A bibliography of 45 references is given.

The production of corn on Richfield silt loam soil, H. A. DANIEL ([*Oklahoma Panhandle Sta., Panhandle Bul. 62* (1937), pp. 3-6).—The data from vari-

etal tests 1923-36 at Goodwell, Okla., considering the number of failures compared with productive seasons, indicated that only in 1928 was corn grown economically in competition with wheat, annual legumes for hay, and sorghum. Surecopper and Brazilian Flour made the highest average yields for the 14-yr. period, but when comparisons were made between all varieties grown during the last 8 yr., 90-day Bloody Butcher, Surecopper, and Dent Squaw led in order.

Developmental morphology of the caryopsis in maize, L. F. RANDOLPH (*Jour. Agr. Res. [U. S.]*, 53 (1936), No. 12, pp. 881-916, figs. 13).—The morphology of the pistillate spikelet, the ovary, and the ovule in corn is described briefly from cooperative studies of U. S. D. A. Bureau of Plant Industry and the [New York] Cornell Experiment Station, and a detailed account is given of the developmental history of the caryopsis, with consideration of the time factor, temperature, and seasonal variations in relation to pollen tube growth, fertilization, and kernel development.

Following pollination the pollen tube becomes established in the silk within from 5 to 10 min., and the male gametes enter the pollen tube within from 2 to 4 hr. at a temperature of from 22° to 24° C. Fertilization occurs within 16 hr. for silk lengths of from 3 to 5 cm and within 23 hr. for silk lengths of from 15 to 18 cm under field conditions with maximum day temperatures of from 25° to 30° and minimum night temperatures of from 13° to 17°. Following fertilization the primary endosperm nucleus divides within from 2 to 4 hr. and the zygote divides within from 8 to 10 hr.

As the caryopsis develops the ovary wall is transformed into the pericarp and the ovule is displaced by the embryo and endosperm except the outer wall of the nucellar epidermis, which becomes the suberized membrane of the mature kernel. The integuments of the ovule virtually disappear in the early stages. Thus the maize caryopsis has no true seed coat. The antipodal tissue frequently persists and at times proliferates to form an extensive starch-filled tissue in the subcrown region of the kernel.

The proembryo develops irregularly in the early stage without a definite pattern of cells or sequence of cell division, and the early cleavage planes could not be identified from 8 to 10 days after pollination when the axis of the embryo proper originated in a lateral position within the proembryo. The epidermis of the proembryo is delimited from 7 to 10 days after pollination.

The differentiation of the coleoptile, seedling leaves, scutellum, and coleorhiza, as well as other details of embryo formation, was traced in a close series of developmental stages. The development of the endosperm from the free nucleate stage to maturity is described, with special reference to the manner in which growth occurs by cell division activity in the epidermal and subepidermal regions in the later stages and the epidermis of the endosperm is transformed into the aleurone layer.

The early development of the cotton fibre, F. M. L. SHEFFIELD (*Empire Cotton Growing Rev.*, 15 (1936), No. 4, pp. 277-286, pls. 4).—Using 12 plants of the Sakel variety grown in the greenhouse, the author traced the development of the fibers from primordial cells in the epidermis. Pollination was found to stimulate cell division in the epidermal layer, and mitosis continued in the epidermis and young hairs were differentiated for a considerable time after flowering. The number of epidermal cells in active division seemed to reach a peak at about the second day, but mitosis occurred to a diminishing extent until at least 10 days after flowering.

Discrepancies in the results of previous workers are apparently due to variations in the rate of development and differentiation in different cells of the same seeds and in different seeds within the same boll.

Time factor in utilization of mineral nutrients by hemp, M. E. TIBEAU (*Plant Physiol.*, 11 (1936), No. 4, pp. 731-747, figs. 9).—A high potassium nutrient solution produced the tallest and most vigorous plants, with the largest and thickest leaves, while potassium deficiency caused stunted growth and copper mottling of the leaves. Plants recovered rapidly from prolonged deficiency, but failed to attain normal growth. A high magnesium nutrient did not affect growth, but a deficiency resulted in chlorosis. Recovery was slower the longer magnesium was withheld. Excess calcium retarded growth, while a deficiency induced paleness, necrotic spotting of the leaves, and early cessation of meristematic activity. Recovery was more rapid after longer periods of deficiency. A high-nitrogen nutrient produced a dark green leafy plant which failed to survive, while the absence of nitrogen resulted in stunting and a pale green color. After a short period of nitrogen starvation the plants made a rapid recovery but died soon after, while from longer periods recovery was slower. Abundance of nitrogen at the time of fruit bud differentiation led to the production of female flowers, while its absence at that time tended to the production of male flowers.

The injurious influence of enormous doses of phosphorus on oats, T. LITYŃSKI (*O ujemnym wpływie nadmiernie wysokich dawek fosforu na owoce, Poznań (Posen): Dziennik Poznań.*, 1935, pp. 23: Eng. abstr., pp. 21, 22).—The plants in the two series received, respectively, 10 and 0.25 g of P_2O_5 per pot, given in the form of $CaHPO_4$ and as a neutral mixture of $(NH_4)H_2PO_4$ and $(NH_4)_2HPO_4$. Whitening and yellowing of the leaf margins and drying of the foliage followed the use of the larger amount, and these plants assimilated a much greater amount of phosphorus than the other series. Only a small portion taken up was converted into organic compounds, the greater part occurring in the cell sap in the mineral form. There was no significant difference in the protein and nonprotein nitrogen compounds or in the mineral content of the two series. The base:acid ratio in plants receiving the normal dosage was 2:1, while in those with the higher dosage it was 2:2. It is believed that the physiological disturbance in the latter group was due to the increased acidity of the cell juices without any increase in the soil acidity.

Nutritional levels in the peanut plant: Contributions from the Hull Botanical Laboratory, R. H. MOORE (*Bot. Gaz.*, 98 (1937), No. 3, pp. 464-490, figs. 2).—In this study by the Puerto Rico Experiment Station, the greatest vegetative extension and fruitfulness of the plant occurred under the same cultural treatment. All high-nitrogen plants were dark blue green, slender stemmed, and succulent, while all high-carbohydrate plants were very pale yellow green, relatively thick stemmed, and firm. Both groups were weakly vegetative and nonfruitful. From the highest nitrogen to the highest carbohydrate series the percentage of dry matter and total carbohydrates increased, and that of soluble solids and total nitrogen decreased, consistently with vegetative and reproductive responses. The root fractions increased in percentage of soluble solids. "Hemicelluloses" were not correlated with levels of nutrition. High carbohydrate conditions favored a slightly higher percentage of ether extract in seeds and gynophores, a suppression of rancidity in the seeds, and development of marginal hairs on the leaflets. Gynophore development was precocious. The mode of the flower-to-gynophore interval was influenced only slightly by enlargement of the fruits on older gynophores or by extensive variations in metabolic levels, but elongation of the gynophores was abruptly inhibited by extreme levels of nutrition. The fruiting tendency was less sensitive to nutritional change than in tomatoes. When grown in the light, the concentration of the phosphate ion in nutrient solutions must be greatly reduced to obviate

injury. Ammonium nitrogen nutrient solutions not precipitating when applied at pH 7.1 are reported, and a method for determining nitrates by a 6-hr. aeration period is described. A bibliography of 25 references is included.

Soil and plant response to certain methods of potato cultivation, G. C. MOORE ([*New York*] *Cornell Sta. Bul.* 662 (1937), pp. 48, figs. 20).—In studies at Ithaca, N. Y., with Smooth Rural potatoes grown on Dunkirk silty clay loam for 3 yr. and on Dunkirk gravelly sandy loam for 1 yr., comparisons were made of deep v. shallow planting followed by both deep and shallow covering of the seed piece, level moderate ridging v. extreme ridging methods as to effects of scraping v. cultivation, side dressing with nitrates v. initial fertilizer application only, and of irrigation v. rainfall on soil and plant response.

Emergence was hastened by deep planting from 2 to 3 days over shallow planting and by an additional 2 to 3 days by covering the seed pieces shallow, but final stands were about the same. Yield differences did not follow deep and shallow covering at either planting depth. Soil moisture in the first 12 in. of soil decreased with increasing height of ridge, the rate of loss being most rapid in ridge and least in level culture. Cultivation conserved a small amount of moisture as compared with scraping. Soil nitrates, especially following tuber set, were higher in ridges than in level soil but did not differ when scraping was compared with cultivation. Soil temperature at the seed piece level averaged about 1° F. lower in level than in ridge culture over a 24-hr. period, bearing an inverse relationship to soil moisture. Scraping seemed to favor a higher temperature in level soil but a lower one in 4-in. ridges.

Roots were much more fibrous in ridged soil than in level culture, but their depth of penetration was not materially different. Pruning by cultivation was less in ridged plats because of the more vertical direction of the roots. Tuber shape was not influenced by cultural treatment; yields were greatest on level culture, decreasing with increasing height of ridge; while sunburning and number of tubers per plant were decreased by ridging. High positive correlation between soil moisture and tuber yield indicated that moisture accounted largely for the yield differences between cultural treatments. Irrigation in addition to rainfall eliminated differences between these treatments, being most beneficial on the higher ridges and least on level culture. Soil nitrates, comparatively high in the growing season following tuber set, tended to reduce yields slightly. Root pruning alone accounted for considerable yield reductions, mostly owing to a reduction in spread and depth of penetration of the root systems of the plant which is, in turn, manifested by a reduction in size of top. Difference in maturity due to treatment was not observed.

Practical advantages of the furrow-planting shallow-covering method of culture under New York conditions are indicated, with suggestions for ridging where necessary and for cultivation with either type of culture.

Influence of the chloride ion on the content of carbohydrates in potato leaves, S. S. BASLAVSKAJA (*Plant Physiol.*, 11 (1936), No. 4, pp. 863-871, figs. 3).—It is concluded from this study that large doses of chlorides decrease the total carbohydrates of the leaves. This is obviously correlated with a lowered chlorophyll content per unit of leaf area and a weakened photosynthetic activity. The leaves of plants of the chlorine series were relatively richer in starch than those of the controls, a phenomenon as yet unexplained.

Commercial agricultural seeds, 1936, G. P. STEINBAUER (*Maine Sta. Off. Insp.* 162 (1936), pp. 120-135).—The purity, weed seed content, germination, and in the case of legumes the hard seed percentage are tabulated for 99 samples of agricultural seed collected from dealers in Maine in 1936.

HORTICULTURE

New approaches to edaphic and nutritional problems with horticultural plants, H. H. ZIMMERLEY (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 707-719).—In discussing the present trends in research relating to soil and nutritional problems with horticultural crops, the author reviews recent work on soil reaction, rapid chemical tests of nutrient needs based on plant sap and on the soil itself, effective placement of fertilizers, etc. He emphasizes the desirability of the horticulturist working with the soil technologist, the agricultural chemist, and the agricultural engineer.

[Horticultural studies by the Delaware Station] (*Delaware Sta. Bul.* 205 (1936), pp. 34-36).—Information is presented on physiological dropping of fruits as related to curculio sting injury and growth of peach fruits, both by L. R. Detjen and E. W. Greve; and variation in the growth of apple trees on their own and on seedling roots, by F. S. Lagassé.

[Vegetable and flower studies by the Iowa Station] [*Iowa Sta. Rpt.* 1936, pts. 1, pp. 146, 158, 169, 170-172, 173; 2, pp. 37, 38, 41, 42, figs. 2).—Brief reports are presented in part 1 on inheritance in the tomato, by E. W. Lindstrom; culture of asparagus, by A. T. Erwin and E. S. Haber; fertilizer and green manure for muskmelons, and substitute crops for cabbage and melon "sick" soils of southeastern Iowa, both by Erwin; factors affecting the quality and marketing of cantaloups, by Erwin and G. S. Shepherd; varieties of tomatoes and beans, by Erwin and Haber; varieties of muskmelons, by Erwin and N. D. Morgan; influence of temperature and moisture on growth of asparagus, by Haber; and varieties of peony and iris, by E. C. Volz. In part 2 brief mention is made of the progress of experiments in sweet corn breeding and on nature of drought resistance in inbred and hybrid lines of sweet corn, both by Haber.

[Horticulture at the North Louisiana Substation], R. E. WRIGHT (*Louisiana Sta., North Louisiana Sta. Bien. Rpt.* 1935-36, pp. 16, 17, 18, 19, 20, 21).—The results are presented briefly of varietal, cultural, and fertilizer tests with watermelons and tomatoes; variety trials with pecans, apples, peaches, and muscadine grapes; and a production test with tung oil.

[Horticultural studies conducted by the New Mexico Station] (*New Mexico Sta. Rpt.* 1936, pp. 53-55, 56, 57, 59-61, 63-65, fig. 1).—Among investigations, the progress of which is discussed, are phenological investigations with fruits and nuts, variety tests of fruits, orchard heating, time of planting head lettuce, varieties of pecans, varieties of sweet peas, narcissus, tulips, hyacinths, gladioli, and dahlias, varieties of raspberries, fertilizer and irrigation studies with onions, vegetable seed production, and effect of fertilizers and frequency of irrigation on yield and quality of the early Grano onion.

Insecticides and fungicides, 1936, E. R. TOBEY (*Maine Sta. Off. Insp.* 162 (1936), pp. 136-142).—The results are presented of analyses of 56 samples of insecticidal and fungicidal materials.

Wax emulsions for spraying nursery stock and other plant materials.—A preliminary report, E. J. MILLER, J. A. NEILSON, and S. L. BANDEMER (*Nichtigan Sta. Spec. Bul.* 282 (1937), pp. 39, figs. 4).—Based on 5 years' studies on the development and use of wax emulsions that may be sprayed on plants to produce protective films, the authors conclude that the results, although still incomplete, suggest the usefulness of the emulsions for reducing desiccation in nursery stock and other plant material. In only two cases, that of small 1-yr. seedlings of larch and red spruce, did the application of the standard emulsions cause appreciable injury and even in this case the poor results are believed due to some fault in the preparation of the materials. The rela-

tion of soil moisture to successful use of emulsions is pointed out, the greatest benefits coming where soil moisture is below optimum quantity, but for dormant deciduous and coniferous plants, for the protection of tree trunks against sun scald, coating of scion wood, scale and borer control, Christmas tree spraying, and the protection of conifers from winter injury, two applications of the emulsion containing 13.8 percent of solids are considered desirable. This concentration represents approximately the maximum that can be employed satisfactorily with most equipment at working temperatures which must be above 32° F. For spraying seedling annuals and perennials, the authors suggest dilution of the emulsion with 2-5 times its volume of water. Some information is included on the use of the emulsion on apples in storage.

Experiments on electric, coal, gas, kerosene, and manure-heated hotbeds, G. J. STOUT, W. B. MACK, J. E. NICHOLAS, and D. C. SPRAGUE (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 605-609).—In this further contribution (*E. S. R.*, 72, p. 770) from the Pennsylvania Experiment Station, the authors present more of the technical features of the investigation. Reports on plant growth for two growing seasons showed quicker germination and earlier appearance of the seedlings when the source of heat was below the soil surface. Manure-heated beds produced plants of more stocky growth, and in the case of the tomato the plants weighed nearly twice as much each as from any other treatment at the time of lifting for field planting.

Home vegetable gardening in Kansas, W. B. BALCH, (*Kansas Sta. Circ.* 181 (1937), pp. 45, figs. 17).—General information is presented on planning the garden, preparing the soil, fertilizers, planting, specific cultural requirements of the different vegetables, control of pests, storage, etc.

The effect of temperature, humidity and wind velocity on blossom drop of garden beans, H. J. THOMSON ([*Oklahoma*] *Panhandle Sta., Panhandle Bul.* 62 (1937), pp. 7-16, fig. 1).—Samples of blooms collected at repeated dates in 1936 from Burpee Stringless Greenpod plants sown June 29 and watered at from 6- to 11-day intervals throughout their lives all showed abundant pollination. The abortion of flowers was due apparently to low pollen germination and slow tube growth under conditions of high temperature. Although the tender flower organisms were protected by the keel, the stigma and style were dried by excessive transpiration due to low relative humidity. Wind had a twofold effect on blossom drop—(1) direct injury by physical force, and (2) injury by drying.

Relation of plot size and shape to variability of carrot yields on peat soils, T. M. CURRENCE (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 484-488, fig. 1).—Using Fisher's analysis of variance, it was found in this study by the Minnesota Experiment Station upon yield data taken in a uniform block of carrots located on a peat bog, that six replications of a single row plot, three rods long, would provide a satisfactory measurement of yield variation to bring out a significance of 10 percent. The single row, three-rod plots showed practically as small variation as any arrangement and were of a convenient shape and size for study. Increasing the length of row was more effective in reducing error than was widening the plot. Considerable soil heterogeneity was indicated despite the uniform appearance of the field.

A study of the rest period of chives, J. P. MCCOLLUM (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 491-495, figs. 2).—Stating that about October 1 (dependent on prevailing weather) chives enter a 3-mo. rest period during which growth is very slow and irregular, the author discusses experiments conducted by the Illinois Experiment Station to overcome this condition. Neither shading in the field from September 16 to October 23 nor topping had any beneficial

effect and, in fact, decreased vigor. Removal of plants to a warm greenhouse on September 16 prevented their entering into rest, but the most successful practice was the exposure of plants taken from the field after they had entered the rest period to a temperature of 110° F. for 48 hr.

New hybrid sweet corns, W. D. ENZIE (*Farm Res. [New York State Sta.]*, 3 (1937), No. 3, pp. 7, 8).—Brief descriptions are presented of the more promising varieties recorded in 1936, trials of 32 varieties of yellow hybrid inbreds, top crosses, and open-pollinated sorts, and of 6 white hybrids and top crosses.

New sweet corns resistant to earworm, C. F. POOLE (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 496-501).—At the California Experiment Station, Davis, five varieties, Honey June, Surcropper Sugar, Oregon Evergreen, Alameda, and Purdue Bantam, of different maturing seasons and possessing different degrees of resistance to earworm, were planted (1) all on one day and (2) at intervals to insure concurrent silking. Records of earworm injury showed the varieties to follow practically the same order of susceptibility in both plantings, indicating that the different degrees of resistance were not caused by differences in time that silks appeared but rather to inherent differences in the varieties. Crosses between the resistant varieties Honey June and Surcropper Sugar and comparatively susceptible varieties such as Golden Bantam, Alameda, Oregon Evergreen, Golden Sunshine, and Early Golden and backcrosses of F₁ seedlings to both parents yielded evidence that insect resistance is heritable. In three cases, hybrids were possibly superior to both parents in their resistance.

Variety tests of sweet corn and its resistance to corn earworm and smut injury, E. F. BURK, C. B. CROSS, and E. HIXSON (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 502-504).—Observations by the Oklahoma Experiment Station on 39 varieties and strains of sweet and other corns harvested in the roasting ear stage showed a rather marked relationship between tightness of the husk and freedom from corn earworm injury. Varieties classified as tight husked had 67.3 percent marketable ears with few severely damaged, while those with loose husks had only 40.9 percent marketable ears and a relatively high percentage of badly injured ears. Smut was abundant, particularly in plants grown from southern seed.

Further studies of earworm damage in sweet corn varieties in Texas, L. R. HAWTHORN (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 505-507).—Repeating the work of 1933 (*E. S. R.*, 72, p. 329) with the addition of several new varieties recently developed by various experiment stations, it was observed that although the infestation was more severe in 1935 as judged by percentage of infested ears the varieties taken as a whole were injured less than in 1933. The author attributes this favorable situation to the fact that the varieties in 1935 were on the whole definitely more resistant to the earworm. The five most resistant varieties in descending order were Georgia 439, Honey June No. 1, Georgia 428, Mexican June, and Honey June No. 2. The least resistant variety of the entire twenty tested was Hopeland, with only 42.9 percent marketable ears as compared with 89.1 percent in Georgia 439.

Bulb formation in some American and European varieties of onions as affected by length of day, R. MAGRUDER and H. A. ALLARD (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 489, 490).—A large number of varieties of onions were grown at Arlington Farm, Virginia, under normal light intensity but with its duration regulated, in the summers of 1934 and 1935. In 1935, two lots were supplied electric light in addition to daylight to lengthen the photoperiod to 16 and 18 hr. Increasing the length of the photoperiod hastened maturity in all varieties, but considerable variation was shown in the

minimum period required for bulb formation and in the rate and uniformity of bulb formation at superminimal photoperiods. Yellow Bermuda was the only onion to produce any good bulbs with 10 hr. light. Data are given on the minimum number of hours of light required to produce 100 percent of normal bulbs in the various varieties and strains. The value of the photoperiod test for determining the adaptability of a new onion to any given region is stressed.

The pungency of onion bulb as influenced by the stage of development of the plant, H. PLATENICS and J. E. KNOTT (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 481-483, figs. 2).—Observations by the Cornell University on the amount of volatile sulfur in Italian Red, Valencia, and Long Keeping Yellow Globe onions harvested at different stages of maturity showed an increase in volatile sulfur as maturity increased. Varieties differed in their volatile sulfur content in accordance with their known pungency. A second trial in which Ebenezer, Italian Red, and Valencia onions were sampled at 2- to 3-week intervals beginning July 5 showed the same general trend. The peak in volatile sulfur was reached just before the tops began to fall. Since this stage was reached at different times in the three varieties, it was evident that growth stage and not environment was the causal factor. Since onions undergo fairly rapid changes in pungency in storage, the authors stressed the need of prompt determinations of volatile sulfur after sampling.

Bolting habit in the onion, H. A. JONLS, C. F. POOLE, and S. L. ELSWELLER (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), p. 490).—Certain onion varieties such as Italian Red, California Early Red, and Stockton Yellow Globe sown in central California in late August and transplanted to the field in late November and December showed a marked tendency to seed prematurely in seasons characterized by warm autumns and cool springs. When the autumn was cool and the spring warm, bolting was very slight. Progress was made by the California Experiment Station at Davis in the development of lines with much less tendency to bolt even under conditions favoring this phenomenon.

Morphology of the flower, fruit, and seed of *Raphanus sativus* Linnaeus, M. E. ROSELL (*Philippine Agr.*, 25 (1936), No. 6, pp. 521-540, figs. 37).—A description is presented of the development of the flower, gametophytes, fruit, and seed of the radish.

Correct handling of tomato plants pays, W. T. TAPLEY (*Farm Res. [New York State Sta.]*, 3 (1937), No. 3, pp. 12, 13).—General information is presented on the growing of tomato plants, setting in the field, and subsequent care. The author suggests that if the grower has the right facilities and follows the correct procedure, it is likely he can grow better plants than he can secure elsewhere.

New uses for fruits and vegetables, D. K. TRESSLER (*Farm Res. [New York State Sta.]*, 3 (1937), No. 3, pp. 14, 16).—Special reference is made to the new quick-freezing and dehydrating processes and to the fruit and vegetable juice industry as a means of disposing of unusually large crops. The use of frozen fruits and vegetables and the future of the industry are considered.

[Pomological investigations by the Iowa Station] (*Iowa Sta. Rpt. 1936*, pt. 1, pp. 158-168, figs. 3).—Included are reports on studies on the development of uniform and desirable apple stocks, by T. J. Maney and B. S. Pickett; correlation of bound water in apple wood with hardness, by Maney; behavior of apple varieties in different storage temperatures, by H. H. Plagge; systems of soil management for apple orchards, by Pickett and Maney; breeding of apples, by H. L. Lantz, Pickett, and Maney; pear breeding, by Pickett and Lantz; plum breeding, by Pickett, Lantz, and Maney; breeding harder varieties of peaches, by Maney, Lantz, and Pickett; apple varieties, by Lantz, Pickett, and

Maney; breeding of black raspberries immune to anthracnose, by Maney; crushed firebrick as a rooting medium for greenhouse and nursery plants, by Pickett and V. T. Stoutemyer; respiration in stored Jonathan apples as related to soggy breakdown and other troubles, by Plagge; adaptation and culture of strawberry varieties in southeastern Iowa, by Maney and Pickett; influence of stock on the yielding capacity of apples, by Maney; and propagation of apple as associated with juvenile forms and adventitious buds, by Pickett, Stoutemyer, and A. F. Dodge.

Farm orchard investigations, O. R. MATHEWS and V. I. CLARK (*U. S. Dept. Agr. Circ. 421 (1937), pp. 43-45*).—Among subjects discussed are the spacing of fruit trees, protection of trees from rabbits, testing of apple and plum varieties, and general suggestions for the establishment and maintenance of fruit plantations.

Hardy fruits, with special reference to their culture in western Canada, C. F. PATTERSON (*Saskatoon, Sask.: Author, 1936, pp. XVI+321, figs. 62*).—This is a general discussion of varieties, culture, propagation, pruning, spraying, etc.

Pollination and fruit setting, A. E. MURNEEK (*Missouri Sta. Bul. 379 (1937), pp. 28, figs. 18*).—Among subjects discussed in this bulletin, designed primarily for the fruit grower, are the process of pollination and fertilization, fruitfulness and sterility, interfertility among apple varieties, effective pollinizers, the blooming periods of different varieties, suggestions for interplanting to secure favorable pollination, the role of bees in orchard pollination, effects of weather and tree vigor on fruit setting, apple drops, overbearing as related to biennial fruiting, and the pollination of various fruits such as pear, peach, cherry, plum, grape, and cane fruits.

The results of 50 years of breeding apples, G. H. HOWE (*Farm Res. [New York State Sta.], 3 (1937), No. 3, pp. 3, 8*).—This, the second in a series (E. S. R., 76, p. 795), describes further promising apples originated by or tested by the station. Of the many varieties utilized as parents, McIntosh and Delicious are said to have yielded the greatest number of meritorious seedlings. Red sports from different sources are given special consideration in the discussion.

Root growth in young apple trees made shortly before and after defoliation, A. J. HEINICKE (*Amer. Soc. Hort. Sci. Proc., 32 (1935), pp. 164, 165, fig. 1*).—A comparison at Cornell University of the root development of young McIntosh apple trees defoliated on September 15 with that of comparable nondefoliated trees showed that root activity was greatly retarded by leaf removal. The author points out that if there is any advantage in having a considerable root growth in late autumn, conditions should be made favorable for leaf retention. In the control trees relatively little new root development took place after the leaves had fallen.

The relationship between the internal structure and photosynthetic behavior of apple leaves, W. F. PICKETT (*Kansas Sta. Tech. Bul. 42 (1937), pp. 58, figs. 7*).—In this summation of a comprehensive study, a preliminary report upon which has been noted (E. S. R., 74, p. 202), the author points out that under similar environments the leaves of different apple varieties vary in their rate of photosynthetic activity and that this different capacity is correlated with the extent of the intercellular space. There were, however, other factors influencing photosynthesis, including chlorophyll content, nitrate and moisture supply, temperature, and carbon dioxide content of the atmosphere. Among varieties, the Livland ranked high in rate of photosynthetic activity per unit area of leaf. York Imperial, under comparable conditions, rated consistently lower and had at the same time a much lesser extent of intercellular

space. The author suggests that the low activity of York leaves may be one of the factors underlying the well-known biennial fruiting habit of this variety.

Studies of stomata showed the Livland leaves to have the smallest number per unit of area of any of the varieties studied. The Livland stomata were, however, longer than those of any other variety. Fewer stomata were open in the morning in the Livland and Wealthy than in the other varieties.

Determinations of gain in dry weight of unit area taken from leaves of different varieties showed that the daily maximum temperature exerts a pronounced influence on the dry matter gain. In general, the higher the temperature the lower the gain. During three consecutive seasons, York Imperial made lower daily gains in total dry matter and lower gains in total hydrolyzable carbohydrates estimated as glucose than did any of the other varieties under study.

The photosynthesis, transpiration, and stomata of apple leaves as affected by certain nutrient deficiencies, N. F. CHILDEES and F. F. COWART (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 160-163).—At Cornell University young McIntosh apple trees growing in the greenhouse in containers of sand and supplied with nutrient solutions lacking in one or more of the major plant food elements were examined with respect to transpiration, photosynthetic activity, and stomatal movement. The absence of nitrogen from the nutrient solution caused by far the greatest reduction in carbon dioxide assimilation and in transpiration per unit of leaf area. The maximum assimilation of carbon dioxide occurred in the full nutrient plants, with the minus P plants approximately equal. The absence of P or K, or both, had little effect on transpiration. The number of stomata per given area was greater in leaves of plants deficient in certain elements, particularly N, but the stomatal movement of plants deficient in N was distinctly sluggish.

The effect of some summer oil sprays upon the carbon dioxide absorption of apple leaves, R. A. SCHROEDER (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 170-172).—Applying sprays with a hand atomizer to the leaves of potted Delicious apple trees and using a modified Heinicke and Hoffman apparatus for measuring CO₂ assimilation, the author found at the University of Missouri that with both increased viscosity and increased percentage of oil in the spray there is an increase in the amount of reduction of carbon dioxide absorption. There was no great difference between oils of 80 and 110 viscosity. A further reduction in carbon dioxide assimilation was noted following the application of a second spray. The recovery of leaves was less with vegetable than with mineral oils.

Blossom performance of Newtown terminal growth in relation to alternate bearing, pruning, and thinning of fruit, G. G. BROWN (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 693-699).—Yield data taken in 1934-35 by the Oregon Experiment Station on Newtown apple trees which prior to the removal of alternate trees in the spring of 1933 had lapsed into pronounced biennial bearing showed definite indications of a return to annual fruiting. An application of 6 lb. of nitrate of soda per tree per year was involved in the favorable response. Comparatively severe pruning of some of the trees in 1933 had no material effect on yields in 1934, but thinning of the fruit in 1934 did influence 1935 production. In all cases where the fruit was thinned from 10 to 12 in. in 1934, yields in 1935 were decidedly larger than on trees the fruit of which was thinned to 6 in. The grand average of all buds, terminal and axillary, on 1933 terminals which differentiated bloom during the first year of growth and on extensions thereon during 1934, was 14.1 percent for the 6 in. thinned plats and 27.84 percent for the 10 to 12 in. plats.

Studies to determine the effect of "Freon" in the atmosphere upon apples in cold storage, C. E. BAKER (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), p. 214).—"Freon", a proprietary refrigerant of practically no odor and when used as a compressible gas of much lower temperature-pressure relationship than ammonia, was studied by Purdue University as to its effect in various concentrations and at various temperatures on Delicious, Golden Delicious, and Winesap apples. Under the prevailing conditions, there was noted no injury to the fruit that could be attributed to the gas except when the air was almost completely replaced. When the concentration simulated that involving refrigerant leaks of considerable extent and duration, no injury was observed. Considerable quantities of the gas were inhaled by the author without apparent harm.

Wrapping Golden Delicious apples in moisture-proof cellulose sheets to prevent shriveling in cold storage, C. E. BAKER (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), p. 213).—Experiments conducted by the Purdue University over a period of 3 yr. indicate that wrapping in a moisture-proof grade of transparent cellulose prevents wilting to a high degree and over a long period. Under the same conditions, unwrapped apples in tub baskets with paper liners and pads were unsalable by early winter. Golden Delicious apples appeared to withstand tight wrappers much better than did Grimes Golden and some other varieties.

Decreasing the germination delay in stone fruits [trans. title], F. HILKENBÄUMER (*Landw. Jahrb.*, 82 (1936), No. 6, pp. 883-924, figs. 4).—Working with plum, sweet cherry, sour cherry, and peach seeds, the author found that the seeds of different mother trees within a species exhibit material variation in their germination. When seeds were not removed immediately from the flesh at harvest, or the fruits were fermented even for a short time, germination was delayed and reduced. Of four media, peat, sand, sand and peat, and peat and soil, peat was most effective in hastening germination. Germination was increased by peat only in the case of the mahaleb cherry and the peach. Low and varying temperatures in damp storage reduced germination except in the peach. Storage and seedbed temperatures over 12° C. hindered germination. Temperatures from -10° to -05° had no beneficial or harmful effects on air-dried seed. The several species had different optimum germination temperatures. Immersion in water at 12° had no effect on germination, except in the case of the mahaleb cherry. At 24° germination was decreased and delayed. Various chemical agents, such as sulfuric acid and chloride of lime, were tested and for the most part were accelerating to germination. The bony seed shell delayed germination only to a certain degree. The causes of delayed germination are said to rest in the specific nature of the seed and not in external factors such a seed shell.

Why is one half of a peach larger than the other? H. B. TUKEY (*Farm Res. [New York State Sta.]*, 3 (1937), No. 3, p. 11, fig. 1).—This is a popular discussion of the investigations previously noted (E. S. R., 77, p. 48).

Missouri peach culture, T. J. TALLENT (*Missouri Sta. Bul.* 380 (1937), pp. 30, figs. 12).—General information is presented on locating orchard sites, selection of varieties, methods of planting, general culture, pruning, fruit thinning, control of pests, and harvesting and marketing practices.

Studies on the effect of humidity in the cold storage of fruits, F. W. ALLEN and W. T. PENTZER (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 215-223, figs. 4).—In studies conducted jointly by the University of California and the U. S. Department of Agriculture, it was observed that in the case of Emperor grapes saturated atmospheres were needed to approach suspension of moisture loss

and that transpiration increased with each decrease in relative humidity down to 40 percent. Weight loss of 1.2 percent did not cause shriveling. A relative humidity of 85 percent proved most satisfactory for Emperor grapes. Likewise with apricots, plums, peaches, and apples, a saturated atmosphere was required to prevent moisture loss. High relative humidity had no apparent detrimental effect on pears or apples and little upon sound plums held at 32° F., although some mold appeared on the exterior of the packages after 4 to 8 weeks. Apricots held for 10 days at a relative humidity of 95 to 100 percent and at 50° tended to take on a watery appearance before becoming fully ripe. In general, deciduous fruits held at about 32° were most attractive in appearance and texture when the humidity was maintained at 90 percent or above.

Red Lake, a promising new currant (*Farm Res. [New York State Sta.], 3 (1937), No. 3, p. 2*).—A brief description is presented of a new variety originated by the Minnesota Experiment Station.

Grape pruning in Illinois, V. W. KELLEY (*Illinois Sta. Circ. 468 (1937), pp. 16, figs. 11*).—Among material covered in this circular of general information is the need of pruning, methods of training, construction of trellises, relation of number of buds to production, renewal of neglected vines, and the inter-relationship between pruning and training and other factors in the management of vineyards.

A manurial experiment on bananas, R. C. WOOD (*Empire Jour. Expt. Agr., 4 (1936), No. 16, pp. 365-367, fig. 1*).—In studies at the Imperial College of Tropical Agriculture, Trinidad, the addition of potash to manures supplying nitrogen gave profitable increases in the yield of Dwarf Cavendish bananas. On the addition of phosphorus to the nitrogen and potash materials, however, the yields were less than with these materials alone.

Rootstock and scion influence in citrus, R. W. HODGSON, S. H. CAMERON, and E. R. EGGER (*Calif. Citrogr., 22 (1937), No. 3, p. 110, figs. 2*).—At the end of their seventh growing season, trees of trifoliate orange budded on trifoliate and rough lemon stocks and of rough lemon budded on rough lemon and trifoliate orange were carefully dug and records taken of top and root growth. Using as standards for comparison the trees budded on themselves, it was found that the rough lemon scion had greatly stimulated trifoliate rootstock and reciprocally the trifoliate scion had markedly reduced the growth of the rough lemon rootstock. By far the largest tree of all was the rough lemon budded on itself and the smallest tree was the trifoliate orange budded on itself. Rootstock and scion influences appeared to be reciprocal in nature.

Effect of humidity on transpiration of rooted lemon cuttings under controlled conditions, J. BIALOGIEWSKI (*Amer. Soc. Hort. Sci. Proc., 32 (1935), pp. 166-169, figs. 2*).—Using rooted Eureka lemon cuttings possessing three or four mature leaves or rooted single leaves growing in an artificially controlled environment, the author found, in studies conducted by the University of California, that the loss of water from rooted lemon cuttings was not directly related to the saturation vapor pressure deficit. At 30° C., the rate of transpiration is a function of humidity in the range of 95 to 60 percent humidity. A very pronounced retardation was recorded below 60 percent. At 25° and 20° the effect of external factors is most accentuated in a straight line relationship between transpiration and relative humidity.

Cold storage studies of Florida citrus fruits, I, II, (*Florida Sta. Buls. 303 (1936), pp. 67, figs. 13; 304 (1936), pp. 78, figs. 23*).—Two bulletins are presented.

I. Effect of temperature and maturity on the changes in composition and keeping quality of oranges and grapefruit in cold storage, A. L. Stahl and A. F.

Camp.—Studies of the effect of temperature and maturity on the keeping quality and changes in composition of freshly harvested, untreated, and unwrapped oranges and grapefruits held at 32°, 37.5°, 42°, 48°, 54°, and 58° F., with relative humidity approximating 85 to 90 percent where possible, showed a direct relationship between the rate of change in composition and the storage temperature.

In the Pineapple orange there was noted a decrease in total weight, volume, and percentage of juice, with very slight changes in percentage of sugars, pH, and percentage of citric acid. In the Valencia there was a decrease in total weight, specific gravity, percentage of juice, and percentage of acid and an increase in total sugars with the length of storage. The pH values also increased, suggesting a decrease in effective acidity. Weight losses were less in all varieties at the lower temperatures and increased with greater maturity at the time of harvest. The amount of decay increased with storage temperatures, but 37.5° was better than 32° because fruit kept marketable for a longer time after removal from storage.

In the case of grapefruit, total weight decreased with length of storage. The percentage of free-reducing, hydrolyzable, and total sugars increased, but there was very slight change in acidity. As with the orange, the lower the temperature the less rapid the changes in composition. Considering all factors—weight loss, decay, etc.—37.5° was found the best of the several temperatures for storing grapefruit.

II. *Effect of various wrappers and temperatures on the preservation of citrus fruits in storage*, A. L. Stahl and W. M. Fifield.—In this second paper there are discussed the results of trials of 22 different wrappers for oranges and grapefruit.

The moistureproof wrappers, aluminum foil, cellophane, etc., were found superior in reducing losses in weight and preserving the general appearance of both oranges and grapefruit. In moistureproof wrappers, Pineapple oranges and grapefruit kept 3–4 mo. in good condition, and Valencia oranges for 5 mo., much longer than when unwrapped or when wrapped in ordinary tissue. In the case of the orange, a box liner of moistureproof material was as effective as individual wrappers. In the grapefruit, a combination of moistureproof lining and individual tissue wraps proved very satisfactory and saved material. With both fruits a temperature of 37.5 was again found more desirable than higher or lower temperatures.

Breeding for earliness and hardiness in chrysanthemums, F. L. Mulford (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 690–692).—Stating that in the Northern States there are very few varieties of hardy chrysanthemums that bloom before heavy frost, the author discusses the work of the U. S. Department of Agriculture in the development of early flowering varieties. Of a total of 101 promising seedlings, 34 were early, 31 midseason, and 36 late. There was no apparent correlation between flower type and season of bloom, but there was a slight indication that certain colors, namely, red, blush, and lemon, may possibly be associated with late blooming.

Storage of French marigolds, M. S. Neff and W. E. Loomis (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 683–685).—In experiments at the Iowa State College, French marigolds were found to store better at 40° than at 33° F. Wrapping the flowers in waxed paper reduced turgidity of the blooms and prolonged their life as compared with comparable flowers standing in water. Flowers wrapped in moist moss and waxed paper did not keep satisfactorily because of early maturity and the development of foliage diseases.

The effect of fertilizers on the yield of narcissus bulbs, M. M. PARKER (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 678-682).—At the Virginia Truck Experiment Station large-sized King Alfred bulbs, fertilized at the time of planting with a 2-10-5 mixture applied at the rate of 1,000 lb. per acre, yielded more and heavier bulbs than the nonfertilized plats, but the differences were not significant unless a top dressing of a 9-5-3 material was added the following spring. The effects of fertilizer treatments were more pronounced on smaller bulbs. Fertilization resulted in a decrease in round bulbs and cannot be recommended when the objective is round bulbs for forcing. It is pointed out that the number of flowering stalks the next spring after planting might be decreased by fertilization.

Further experiments with high test pyrethrum strains, B. D. DRAIN, C. B. GNADINGER, C. S. COHL, and G. A. SHUEY (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 201-204).—The results are presented of the analyses for pyrethrin in various vegetative strains of pyrethrum, in individual plants of single strains, and in a new group of selections from seedlings of Swiss origin. In general it was shown that the pyrethrin content is fairly uniform in plants of a single strain, with differences for the most part only slightly greater than would be expected between duplex determinations on a single sample. The evidence supported earlier conclusions (E. S. R., 73, p. 619) that there exist high pyrethrin-producing strains of pyrethrum.

Hardiness tests of some perennial Sedums, E. D. HANSING, L. E. LONGLEY, L. SANDO, and R. B. HARVEY (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 686-689).—A total of 16 species of *Sedum* were tested by the University of Minnesota in freezing chambers as to their resistance to low temperatures. At near-killing temperature, the roots and stems were injured first with the stem tips and leaves retaining the capacity to send forth roots. Species native to central and northern Europe, northern Asia, and northeastern United States proved to be hardy.

A method for determining the nutrient needs of shade trees with special reference to phosphorus, H. L. MITCHELL (*Black Rock Forest Papers*, 1 (1935), No. 1, pp. 4, fig. 1).—Analyses of leaves collected from sample plats established in a mixed hardwood stand, composed mainly of red and chestnut oaks and red maple and fertilized with different amounts of finely ground rock phosphate, showed a close association between soil phosphorus supply and the quantity of this element in the red oak leaves. The phosphorus contents of red maple and chestnut oak leaves were also proportional to the phosphorus supply.

FORESTRY

[Forestry studies by the Iowa Station] (*Iowa Sta. Rpt. 1936*, pt. 1, pp. 142, 144, 145, fig. 1).—Among projects the progress of which is discussed are the establishment and maintenance of nurseries for producing trees and shrubs, and volume, growth, and yield studies with Iowa trees, both by G. B. MacDonald; and the direct seeding of woody plants in erosion control, by A. F. Dodge.

Oregon's forest problems (*Portland: Oreg. State Planning Bd.*, 1936, pp. [7]+19, [pls. 6]).—This report to the Governor and Legislative Assembly of Oregon discusses the importance of the forest resources and the major forest problems of the State, and makes recommendations for policies and legislation.

Shelterbelt investigations, O. B. MATHEWS and V. I. CLARK (*U. S. Dept. Agr. Circ. 421* (1937), pp. 38-43).—Results are presented on trials of species, spacing distances, pruning, comparisons of cultivation, mulching, and no cultivation, and methods of arrangement.

Effect of stand density on mortality and growth of loblolly pine, E. M. SIMMONS and G. L. SCHNUR (*Jour. Agr. Res. [U. S.]*, 54 (1937), No. 1, pp. 47-58).—Continuing studies (E. S. R., 72, p. 629), the authors report that analysis of 25-yr. records of 44 sample plots in old-field stands of loblolly pine (*Pinus taeda* L.) on the Eastern Shore of Maryland show that mortality and growth are both significantly correlated with stand density and basal area. Growth rate increases as density and basal area decrease, but the opposite is true of mortality. Stand density is rigidly determined from the average regression: log number of trees per acre = $4.075 - 1.603 \log$ average diameter breast high. Basal area is significantly correlated with age and site index, but density is not. Growth and mortality may be estimated from tables presented for 5-, 10-, and 15-yr. periods if present density and basal area are known. The errors of estimate are high, but the trends are significant. Estimates of future mortality indicate the minimum amounts that should be removed in thinnings. Growth correlations indicate 15 yr. as the maximum interval between thinnings, and that the shorter the interval the better the results.

Elements of forest mensuration, H. H. CHAPMAN and D. B. DEMERITT (*Albany, N. Y.: J. B. Lyon Co., 1936, 2. ed., rev., pp. 451, figs. 89*).—This is a revised edition of this book (E. S. R., 67, p. 688).

Fire Control Notes (*U. S. Dept. Agr., Forest Serv., Fire Control Notes, 1936, No. 1, pp. 52, figs. 7; 1937, Nos. 2, pp. 53-109, figs. 5; 3, pp. 110-167*).—These, the first three in a new series of publications devoted to the technic of fire control, contain general information on fire prevention and suppression, with brief articles by various workers throughout the Nation on features such as equipment, methods, and experiences.

DISEASES OF PLANTS

Abstracts of papers accepted for presentation at the twenty-eighth annual meeting of The American Phytopathological Society, Atlantic City, New Jersey, December 28-31, 1936 (*Phytopathology*, 27 (1937), No. 2, pp. 119-144).—Abstracts of the following papers are included: Development and Experiences in the Use of Apparatus for Pouring and Washing Agar Plates, by W. E. Ahrens (p. 121); Distribution of Spores of Wilt-Inducing Fungi Throughout the Vascular System of the Elm by the Sap Stream, by W. M. Banfield (pp. 121, 122); Possible Relationship of Stanley's Crystalline Tobacco-Mosaic-Virus Material to Intracellular Inclusions Present in Virus-Infected Cells, by H. P. Beale (p. 122); The Dutch Elm Disease in Europe, by R. K. Beattie (p. 122); A Comparison of Linted and Acid-Delinted Cotton Seed, by J. G. Brown (pp. 122, 123); Symptoms and Terminology in Some Physiogenic Apple Diseases, by A. B. Burrell (p. 123); Boric Acid Treatment of a Physiogenic Apple Disease [Drought Spot, Cork, Rosette, and Dieback], by A. B. Burrell and H. J. Miller (p. 123); Cultural Characters of *Thyrostroma compactum*, From Chinese Elm, by J. C. Carter (pp. 123, 124); The Limitations of Plant Virus Serology, by K. S. Chester (p. 124); Spraying as a Method of Control for Mildew (*Peronospora tabacina*) and Wildfire (*Bacterium tabacum*) in Tobacco Plant Beds, by E. E. Clayton (p. 124); Germination of Conidia of *Peronospora effusa* From Spinach (p. 124) and *Sclerotinia sclerotiorum* on Pyrethrum (pp. 124, 125), both by H. T. Cook; Cucumber Mosaic in Puerto Rico (p. 125) and The Witches'-Broom of *Tabebuia pallida* Caused by a Virus (p. 125), both by M. T. Cook; Savoy, a Virus Disease of Beet Transmitted by *Piesma cinerea*, by G. H. Coons, J. E. Kotila, and D. Stewart (p. 125); Bunch Disease of Pecans [Successfully Transmitted by Grafting], by J. R. Cole (p. 125); Wetwood [a Bacterial Vascular Disease in the Sall-

ceaeae], by B. S. Crandall, C. Hartley, and R. W. Davidson (p. 126); The Interaction of Two Apple-Rotting Fungi [*Schroetinia fructigena* and *Penicillium expansum*], by H. R. X. D'Aeth (p. 126); Reduction of Bordeaux Mixture Injury by the Use of Amendments, by R. H. Daines and W. H. Martin (p. 126); Nitrogen Supply of Sugar Beets in Sand Cultures in Relation to Extent of Injury by Southern *Sclerotium Rot*, by A. E. Davey (pp. 126, 127); Cultural Identification as a Necessary Supplement to Tree Decay Studies, by R. W. Davidson, W. A. Campbell, and D. J. Blaisdell (p. 127); The *Cercospora* Leaf Spot of Rose Caused by *Mycosphaerella rosicola* [n. sp.], by B. H. Davis (p. 127); Some Disease Developments in Forest Nurseries, by W. C. Davis, D. H. Latham, and G. Y. Young (pp. 127, 128); Seed Treatment in Relation to Sand Culture of Seedlings, by A. A. Dunlap (p. 128); *Corticium* Disease of Turf, by L. E. Erwin (p. 128); Environmental Conditions Influencing the Development of Tomato Pockets or Puffs (p. 128) and Environmental Factors Influencing the Development of Blossom-End Rot of Tomatoes (pp. 128, 129), both by A. C. Foster; Factors Affecting the Prevalence of the Spotted Wilt Virus, by M. W. Gardner, C. M. Tompkins, and H. R. Thomas (p. 129); Evaluation of the Geneva Experiment on [Apple] Scab Control, by W. O. Gloyer (p. 129); Breeding Disease-Resistant Chestnut Trees, by A. H. Graves (pp. 129, 130); Control of Club Root of Crucifers, by C. M. Haenseler (p. 130); *Cercospora* Leaf Spot of *Calendula*, by J. G. Harrar (p. 130); Movement of Intracellular Bodies Associated With Peach Yellows, by A. Hartzell (pp. 130, 131); Histological Studies of Infection and Sporulation of *Peronospora tabacina* in Tobacco Seedlings, by R. G. Henderson (p. 131); Inheritance of Plant Characters and Resistance to Fire Blight in Pear, by E. M. Hildebrand and S. L. Hsiung (p. 131); Hereditary Factors Affecting Tobacco-Mosaic Disease in Solanaceous Plants, by F. O. Holmes (pp. 131, 132); Effect of Copper Sprays on Ripening of Tomatoes [New York], by J. G. Horsfall, R. O. Magie, and C. H. Cunningham (p. 132); Studies on a Ring-Spot Type of Virus of Tomato, by E. P. Imle and R. W. Samson (p. 132); Aerial Bacterial Strands in Fire Blight, by S. S. Ivanoff and G. W. Keitt (p. 132); Experimental Spraying for Combined Control of Apple Scab and Fire Blight, by G. W. Keitt and J. B. Carpenter (p. 133); Eradicator Fungicides in Relation to Apple-Scab Control, by G. W. Keitt and D. H. Palmiter (p. 133); Contaminated Soil in Relation to the Epiphytology of Tobacco Mosaic, by S. G. Lehman (p. 133); Crown Gall on *Nicotiana glauca* and *Nicotiana glauca* and the Spontaneous "Tumors" of Their Hybrid, by M. Levine (p. 134); A Growth Hormone in the Development of Crown Gall, by S. B. Locke, A. J. Riker, and B. M. Duggar (p. 134); Inactivation of Tobacco-Mosaic Virus by Ascorbic Acid, by M. Lofkin (p. 134); Comparative Properties of Virus Proteins From a Single-Lesion Strain and From Ordinary Tobacco-Mosaic Virus, by H. S. Loring and W. M. Stanley (pp. 134, 135); An Iris Leaf Disease Caused by *Bacterium tardicrescens* n. sp., by L. McCulloch (p. 135); Isolation of Pathogenic Variants From Pure Cultures of *Bacterium stewartii*, by G. Larson (p. 142); Pathogenicity of a Brown Cultural Variant of *Ceratostomella ulmi*, by J. M. Walter and C. May (pp. 142, 143); Penetration and Invasion of *Phymatotrichum omnivorum* in Cotton Roots Grown Under Pure-Culture Conditions, by G. M. Watkins (p. 143); Antiseptic and Disinfectant Treatments of Flowering Bulbs, by F. Weiss (p. 143); Noninfectious Chlorosis of Perennial Phlox and Its Relation to Phlox Blight, by F. Weiss and T. B. Post (pp. 143, 144); Control of Damping Off of Conifers, by G. Y. Young, W. C. Davis, and D. H. Latham (p. 144); and Pea Streak and Its Relationship to Strains of Alfalfa Mosaic, by W. J. Zaunmeyer (p. 144).

Diseases of plants in the United States in 1935, compiled by H. A. Eboon and J. I. Wood (*U. S. Dept. Agr., Bur. Plant Indus., Plant Disease Rptr., 1936, Sup. 96, pp. 115-289, figs. 20*).—The diseases reported are listed under those of cereal, forage and cover, fruit, nut, vegetable, special, and sugar crops, and under trees and ornamental and miscellaneous plants. Under each of these sections the hosts are given alphabetically by scientific names (with cross references from the common names), and under the hosts the diseases are also listed alphabetically in the following order: Fungus, bacterial, nematode, virus, and nonparasitic. Except for the arrangement, the subject matter is presented in essentially the same way as in other recent summaries. The collaborators are listed by States.

Index of organisms and non-parasitic diseases in The Plant Disease Reporter Supplements 91-96, 1936, N. W. NANCE (*U. S. Dept. Agr., Bur. Plant Indus., Plant Disease Rptr., 1936, Sup. 97, pp. 291-319*)

The Plant Disease Reporter, March 15 and April 1, 1937 (*U. S. Dept. Agr., Bur. Plant Indus., Plant Disease Rptr., 21 (1937), Nos. 5, pp. 85-99, figs. 2; 6, pp. 101-109, figs. 2*).—Notes on the following subjects are included:

No. 5.—A striking example of varietal resistance of roses to crown gall, by F. L. Howard; infectious hairy root (*Phytoplasma rhizogenes*) on rose, by E. M. Hildebrand; a serious blight of the Philippine lily (*Lilium formosanum*) caused by *Botrytis elliptica*, by F. L. Howard; *Fusarium poae* on spring oats in Oregon, by R. Sprague; early development of the apple scab fungus in Massachusetts, by O. C. Boyd; fruit diseases in Idaho, 1936 (including fungus,

bacterial, virus, and nonparasitic diseases, and those of undetermined cause), by E. C. Blodgett; and bean rust (*Uromyces phaseoli typica*) in southern Florida, by G. R. Townsend.

No. 6.—Third experimental forecast of the incidence of bacterial wilt of corn, by N. E. Stevens; and tobacco downy mildew developments to date (mid-March 1937) for Georgia, North Carolina, and South Carolina, by E. E. Clayton.

A contribution to the physiology of diseased plants, V. F. KUPREVICH (W. Th. KUPREWICZ) (*Trudy Bot. Inst. Akad. Nauk SSSR, Eksper. Bot. (Acta Inst. Bot. Acad. Sci. URSS, Bot. Expt.)*, 4. ser., No. 2 (1936), pp. 283-345, figs. 11; *Eng. abs.*, pp. 335-339).—This is a comparative study of the physiological processes in healthy plants v. those infected by various fungus and virus diseases. The material used consisted of *Cirsium arvense* infected by *Puccinia suaveolens*, Victoria field peas infected by *Mycosphaerella pinodes*, *Trifolium hybridum* infected by *Erysiphe communis*, and potatoes infected by mosaic, leaf roll, and aucuba mosaic. A bibliography of 157 titles is included.

Analysis of typical plant diseases from the quarantine standpoint, W. A. McCUBBIN (*Phytopathology*, 26 (1936), No. 10, pp. 991-1006).—An analysis of 200 typical plant diseases from the quarantine standpoint indicates the type of action (embargo, detention, disinfection, inspection, and unrestricted entry) which would be necessary for seeds, propagating materials other than seeds, and commercial products of the chief host, if exclusion of these diseases were aimed at. Summarized results indicate that in these examples embargo is scarcely needed for seeds and would have a minor use for other propagating materials, but would be necessary on a large scale for commercial products. Comparatively few seeds would require detention, but for other propagating materials detention should be freely used. Disinfection, the important procedure for seeds, is only moderately useful for other propagating materials and for commercial products. Inspection of itself has in all three categories a very low rank for exclusion purposes. Many seeds, but very little other propagating material and a rather limited number of commercial products, are held safe for unrestricted entry. Effective quarantine protection is practically attainable for propagating materials, but the need for excessive embargo in the case of commercial products tends to restrict such action to a compromise system far short of perfection.

[Plant disease work by the Delaware Station] (*Delaware Sta. Bul.* 205 (1936), pp. 37, 38, 39-45).—Reports of progress are given on studies relating to the dissemination of peach yellows and little peach by *Macropsis trimaculata* and the masking of peach yellows and little peach in plums and other *Prunus* species, both by T. F. Manns and F. R. Davies; chemical treatments of sweet-potato sprouts and slips for control of wilt and improvement of the set, by Manns and J. W. Heuberger; tomato foot rot (*Macrosporium solani*) control, by Manns; and diseases of cucurbits, bacterial spot *B[acterium] pruni* [= *Phytophthora pruni*], and diseases of soybean, all by J. F. Adams.

[Phytopathological studies by the Iowa Station] (*Iowa Sta. Rpt.* 1936, pts. 1, pp. 97-104, 106-108, 109, 110, 111, 112, 113, 141, 142, figs. 3; 2, pp. 35, 44-49, 49-51, figs. 3).—Progress reports are included in part 1 on the biology and control of *Colletorichum lagenarium* on watermelon, by D. V. Layton; breeding and selection of better wilt-resistant strains of watermelons, by J. J. Wilson (E. S. R., 75, p. 364); physiologic specialization and parasitism of crown rust of oats, and making new strains of oats resistant to crown rust by selection and hybridization, both by H. C. Murphy; control of virus diseases of the potato, by C. S. Reddy; host response and control of leaf spot of sugar beets,

by W. J. Henderson and C. M. Nagel; breeding of sugar beet strains resistant to *Cercospora* leaf spot, by S. M. Dietz, Henderson, and Nagel; development and testing of dust fungicides for control of smut of oats, by Reddy; propagation of disease-free sweetpotato seed stock, by Wilson; seedling structure of wilt-resistant watermelons and the inheritance of fruit shape and flesh color, by J. N. Martin; interaction between spacing and environmental factors in sugar beets, by J. M. Aikman; *Phoma terrestris* and *Fusarium zonatum* on onion in Iowa, by I. E. Melhus and Henderson (E. S. R., 74, p. 353); control of gladiolus diseases in Iowa, by Reddy; apple scab and root necrosis, by Melhus; flax diseases in Iowa, by Reddy; plant pathology phases of barley breeding especially for scab resistance, by Reddy and H. D. Hughes; treatment of wheat, flax, and barley for seed-borne plant pathogens, by G. N. Davis and R. H. Porter; influence of pythiaceae damping-off fungi on seedling stands of legumes and other crops and their control, by Melhus and W. F. Buchholtz; plant disease survey of Iowa, by Wilson, Melhus, Reddy, Porter, Davis, and Henderson; the gumming canker of cherry, damping-off of coniferous seedlings, and a necrosis of the foliage in black walnut seedbeds, all by Melhus; and the control of white pine blister rust in Iowa, by G. B. MacDonald, C. J. Drake, Melhus, and D. R. Lubberts.

In part 2, reports of progress are given on the development of laboratory technics for the detection of seed-borne plant pathogens of corn, by Davis and Porter; genetic investigations of bacterial wilt resistance in corn, by E. W. Lindstrom and E. J. Wellhausen; physiological response of the growing plant and the pathogen to chemical treatments of seed corn, by Reddy; the effect of organic mercury dusts on seeds of corn, oats, barley, and flax, by Porter; fermentation products formed by the action of certain fungi on the byproducts of the corn plant, by J. C. Gilman and C. H. Werkman; factors influencing resistance of strains of corn to *Ustilago car.*, by Melhus and Davis; *Diplodia* dry rot of corn, by Melhus; and the pathogenicity of *Basisporium gallarum* to corn, by Reddy.

[Phytopathological studies by the New Mexico Station] (*New Mexico Sta. Rpt. 1936*, pp. 45, 46, 47).—Reports of progress (E. S. R., 75, p. 56) are given relative to work on apple measles, chlorosis of various plants, and Texas root rot of Chinese elm and other ornamental trees and shrubs.

Organization of the unvalled ascus in two species of *Ceratostomella*, C. F. ANDRUS and L. L. HAETER (*Jour. Agr. Res. [U. S.], 54 (1937), No. 1, pp. 19-46, figs. 7*).—Stages in the multiplication of unvalled cells previous to ascus formation in *C. moniliformis* and *C. fimbriata* include the crosier type of cell division, as well as several other types of direct and indirect cleavage. The position of the spindles at the time of nuclear division probably provides the most reliable indication as to direct or indirect cell division. Cell divisions are accompanied by significant changes in cell shape. A centrosomelike structure is present as a satellite of nucleoli during the prefusion stage. Nuclear fusion in the ascus is followed by three successive nuclear divisions, all alike except in the size of their structures. The spindle axis is a simple rod without evidence of polar bodies or astral rays. Two and later four chromatin bodies appear on the spindle axis, and two bodies move to each pole. The chromosome number in each species is interpreted to be 2 (diploid), and no reduction occurs in the ascus.

Following nuclear divisions, the spore-producing region of the ascus is differentiated as a single vesicle. The vesiculate condition in *C. moniliformis* is evidenced by a cleavage space surrounding the spore-producing region, while in *C. fimbriata* a definite endogenous wall frequently encloses the vesicle.

The data tended to show that the membrane of the spore-producing vesicle is continuous with or derived from the membrane of the fusion nucleus.

The eight ascospores in *C. moniliformis* originate as protuberances on the surface of the protoplasmic sphere contained in the spore-producing vesicle. Each spore becomes enclosed by a wall of cytoplasm originally composing a part of the external ascus. The process of spore formation in *C. fimbriata* is frequently modified to an extent imposed by the presence of a wall enclosing the spore-producing region of the ascus. In both species immature spores appear attached to a common base which is usually lateral to the longer axis of the ascus.

The mature ascus consists of a compact group of spores to which are attached remnants of inert cytoplasm. Deliquescence involves disorganization of the peripheral cytoplasmic layer but does not appear to involve any wall dissolution in *C. moniliformis* and *C. fimbriata*, since the asci possess no external wall. Mature ascospores possess disk-shaped membranous attachments that apparently originate in a manner similar to spore walls and often hold the spores together in pairs or in groups of four.

Liberation of neutralized virus and antibody from antiserum-virus precipitates. K. S. CHESTER (*Phytopathology*, 26 (1936), No. 10, pp. 949-964, figs. 2).—A technic involving moderate heating followed by selective ammonium sulfate precipitation and dialysis resulted in purification of virus-immune serum by the removal of a large proportion of the serologically inactive serum protein, with little or no loss in antibody content but with retention of only a fraction of the nonspecific inhibitory action of unpurified serum. Neutralized precipitates of tobacco-mosaic virus and specific antibody were prepared by titrating the serum with the virus until the mixtures contained an excess of neither antibody nor virus. When such precipitates were partially digested with pepsin, the antibody was destroyed and a large portion of the virus was recovered, as shown by precipitin and infectivity tests. When similarly neutralized precipitates of potato X-virus and its specific antibody were acidified at pH 4.8 or below, the virus underwent dissolution and large amounts of free antibody were liberated. Titrations of X-virus with its immune serum showed that 1 unit of antibody has the power of combining with and being saturated by any number of units of antigen from 1 to 8. Pepsin digestion of tobacco-mosaic virus antibodies alone failed to result in the recovery of virus, suggesting that antibody is not merely antigen which has been slightly modified by the serum proteins. Inoculation of rabbits with antibody did not result in the production in the animal of counter-antibody with antineutralizing properties.

Effect of certain enzymes and amino-acids on crown gall tissues. P. A. ARK (*Science*, 85 (1937), No. 2206, p. 364).—At the University of California crown galls (*Phytoplasma tumefaciens*) of geranium were destroyed in from 4 to 7 days by injection of soft rot bacteria, as were galls of tomato and sunflower. Injection of 0.1 percent water solutions, or placing a few crystals of diastase, papain, pepsin, cysteine hydrochloride, leucine, and isoleucine into crown galls of geranium and sunflower caused them to collapse and dry up within 2 weeks. Tyrosine and tryptophane were ineffective. Pepsin and papain acted most promptly.

Sulphur fungicides. J. F. ADAMS (*Peninsula Hort. Soc. [Del.] Trans.*, 49 (1935), pp. 48-54).—This is a general discussion of sulfur fungicides and progress reports of laboratory tests with lime-sulfur and catalytic sulfur in various concentrations and combinations relative to the toxicity for apple scab spores, and of field spray tests with lime-sulfur, alone and combined with catalytic

sulfur. and wet-milled sulfur for control of scab, sooty blotch, flyspeck, and fruit spot. and with respect to russetting of the fruit.

Pathogenic strains in *Ustilago nigra*, V. F. TAPKE (*Phytopathology*, 26 (1936), No. 10, pp. 1033, 1034).—In a test with the black loose smut of barley (*U. nigra*), 17 host varieties were each inoculated with 10 collections. Two distinguishable pathogenic strains were found and differentiated by their behavior on the varieties Himalaya, Lion, and Nepal.

Varietal testing for the reaction of oats to diseases, especially covered smut, O. S. AAMODT and A. W. PLATT (*Canad. Jour. Res.*, 14 (1936), No. 12, Sect. C, pp. 425-437).—By inoculations (with *Ustilago levis*) of 61 varieties of oats in replicated plats over 2 yr. and of 13 varieties over 3 yr., it was indicated that all gradations in reaction from high susceptibility to apparent immunity exist. Dehulling the kernels before inoculation increased the incidence of smut about six times, but susceptible varieties gave relatively greater increases when dehulled than did resistant varieties. There were no significant differences in total smut obtained between any two of the seasons, but the season influenced the relative varietal reaction.

Spontaneous epidemics of halo blight (*Pseudomonas coronafaciens* [= *Phytophthora coronafaciens*]) and blast provided opportunities for obtaining data on the reactions of a large number of varieties. Immunity to neither of these diseases was observed, though marked varietal differences were noted.

The synthetic production of oat varieties resistant to race 6 and certain other physiologic races of oat stem rust, J. N. WELSH (*Canad. Jour. Res.*, 15 (1937), No. 2, Sect. C, pp. 58-69, figs. 5).—At present, oat varieties classed as resistant to *Puccinia graminis avenae* are resistant to only a certain number of the 10 physiologic races. With the object of combining in a single variety resistance to as many races as possible, a cross was made between the varieties Hajira Strain and Joannette Strain, from which 93 pure lines were obtained. The detailed report of resistance tests with these pure lines forms the bulk of the paper and shows an advance toward the objective noted.

Studies on the control of root-rot diseases of cereals caused by *Fusarium culmorum* (W. G. SM.) Sacc. and *Helminthosporium sativum* P., K., and B.—III, Effect of seed treatment on the control of root rot and on the yield of wheat, J. E. MACHACEK and F. J. GREANEY (*Sci. Agr.*, 15 (1935), No. 9, pp. 607-620; *Fr. abs.*, p. 620).—Continuing this series (E. S. R., 75, p. 58), the authors report that in greenhouse tests seed treatment with Semesan and Ceresan (liquid and dust forms) and with New Improved Ceresan and Uspulun (liquid form) prevented root rot and wilt (*F. culmorum*) in seedlings of wheat, oats, and barley. Cultural studies indicated copper carbonate to be only slightly toxic to *F. culmorum* and *H. sativum*. Seed treatment with formaldehyde (1934) reduced emergence to such an extent that the yield was significantly lower, while the disease rating was considerably higher.

Field tests (1932-34) gave good control of root rots due to both fungi by the organic mercury fungicides, while copper carbonate failed to control. As far as effectiveness for control was concerned, the dust or liquid methods with any of these compounds were of about equal value.

Studies on the control of root rot diseases of cereals.—IV, Influence of mechanical seed injury on infection by *Fusarium culmorum* in wheat, J. E. MACHACEK and F. J. GREANEY (*Canad. Jour. Res.*, 14 (1936), No. 12, Sect. C, pp. 438-444).—Continuing the series, the authors report that in field experiments (1932-34) successful positive attacks of *Fusarium* root rot were experimentally induced. Reduced emergence, increased root rot, and reduced yield uniformly followed the planting of injured seed, and the amount of the

disease increased and the yield decreased with an increase in the degree of seed injury. Mindum and Marquis wheat appeared equally affected by seed injury.

Breeding for smut resistance in Arizona-grown wheat, W. E. BRYAN (*Arizona Sta. Tech. Bul. 66 (1937), pp. 93-123, figs. 4*).—The need for this investigation is based on the fact that the commercial varieties most resistant to *Tilletia tritici* and *T. laevis* are not adapted to Arizona conditions, so that the best use that can be made of them is in crosses with adapted varieties followed by selection in the attempt to isolate new resistant varieties adapted to the State. The data presented are based on studies as to the manner of inheritance of smut resistance and the suitability of a breeding technic for separating the resistant and susceptible forms in the segregating progenies. For this purpose about 2,000 hybrid progenies of the third and later generations consisting of more than 80,000 individual plants were used, for which the 3 resistant varieties Hussar, Riddit, and Hope and the susceptible varieties Sonora and Baart were taken as parents.

Under the experimental conditions it became apparent that a true distribution of the genotypes in a cross with regard to resistance and susceptibility could be determined only by repeated testing of progenies taken from all classes of F_2 . The study has indicated the following necessary steps in breeding for smut resistance in crosses between resistant and susceptible sorts: (1) Selection of the resistant parent, (2) crossing it with the best standard varieties already adapted to the region, (3) growing a sufficiently large number of first- and second-generation hybrids to insure a large number of third-generation progenies, (4) inoculation of the seed of each F_2 plant used for growing the F_3 progenies, and (5) selection of individual plants from zero- and low-infection progenies of F_3 and later generations until immunity or high resistance has been fixed, with care exercised that the seed used in planting each progeny is thoroughly inoculated. The practical value of some of the most promising progenies derived from the crosses noted is briefly discussed.

Controlling damping-off in greenhouse and cold frame, J. G. HORSFALL (*Farm Res. [New York State Sta.], 3 (1937), No. 3, p. 6*).—As a result of 2 years' tests at the station and in commercial greenhouses, red copper oxide spray (1-50) is recommended for control of postemergence damping-off as a valuable supplement to seed treatment with red copper oxide, zinc oxide, or organic mercury (depending on the crop concerned).

The use of bromine in the sterilization of fruits and seeds, C. D. LA RUE (*Science, 85 (1937), No. 2204, p. 319*).—Bromine water diluted to one-tenth its original strength and poured over seeds or pieces of stems, roots, etc., in containers forthwith tightly stoppered proved effective. Oats were injured if exposed over $\frac{1}{2}$ hr., but corn, cabbage, radish, and sunflower seeds withstood 1 hr. or more. Rinsing proved unnecessary.

Fruit and vegetable diseases on the Chicago market in 1935, G. B. RAMSEY (*U. S. Dept. Agr., Bur. Plant Indus., Plant Disease Rpt., 1937, Sup. 98, pp. 15*).—"These notes and data represent material collected by the writer from personal observations on the condition of fresh fruits and vegetables as they arrived on the Chicago market and information abstracted from over 2,000 certificates issued by the inspection service of the fruit and vegetable division of the Bureau of Agricultural Economics in Chicago." The hosts are arranged alphabetically by common names.

Market diseases of fruits and vegetables: Peaches, plums, cherries, and other stone fruits, D. H. ROSE, D. F. FISHER, C. BROOKS, and C. O. BRATLEY (*U. S. Dept. Agr., Misc. Pub. 228 (1937), pp. 27, pls. 11*).—This handbook is

designed "to aid in the recognition and identification of pathological conditions of economic importance affecting fruits and vegetables in the channels of marketing, to facilitate the market inspection of these food products, and to prevent losses from such conditions." It includes 6 colored plates and a list of 67 references to cited literature.

Black stem of alfalfa in Idaho, R. REMSBERG and C. W. HUNGERFORD (*Phytopathology*, 26 (1936), No. 10, pp. 1015-1020, fig. 1).—Studies at the Idaho Experiment Station indicate that this disease is identical with that reported by Johnson and Vallean (E. S. R., 70, p. 194) from Kentucky, the causal organism being *Phoma medicaginis*. The fungus, grown on sweetclover stems, produced an ascigerous stage corresponding to *Pleospora rehmanniana*, which was found also on dead alfalfa stems from the field. Pycnidia of *Phoma medicaginis* were produced on alfalfa and sweetclover in moist chambers after inoculation with a culture of *Pleospora rehmanniana*, which also produced typical black stem symptoms on alfalfa and sweetclover in the greenhouse. Reisolations yielded cultures of *Phoma medicaginis* identical with the original, proving that *Pleospora rehmanniana* is the perfect stage of *Phoma medicaginis*. The ascospores function as inoculum for alfalfa in the spring.

The relationship of Cephalosporium acremonium to the black-bundle disease of corn, M. R. HARRIS (*Phytopathology*, 26 (1936), No. 10, pp. 965-980, figs. 2).—In studies with over 5,000 corn plants, stalks were inoculated by hypodermic needle at all stages of growth with a spore suspension of the fungus *C. acremonium*. A majority of these escaped infection. In a histological study of vascular bundles of various strains of corn, the black condition of the vascular bundles was found to be caused by a deposit of a gummy material containing pentoses, *C. acremonium* being present only occasionally but always associated with the gum. Cornstalks free of the black bundles could not be inoculated with the fungus. The black-bundle condition was found to be caused by unfavorable environmental conditions in some inbred strains of corn. In others it appeared to be a hereditary condition. In no case in which the fungus was isolated was there indication of active pathogenicity by attack through uninjured root systems or invasion of normal vascular elements, but in all instances it had apparently developed only after severe root injury in cornstalks where gum was already present in the bundles.

Resistance to bacterial wilt of open-pollinated varieties of sweet, dent, and flint corn, S. S. IVANOFF (*Jour. Agr. Res. [U. S.]*, 53 (1936), No. 12, pp. 917-926, figs. 2).—In this study by the Wisconsin Experiment Station in which 92 sweet, 17 dent, and 11 flint corn varieties were tested for resistance by artificial inoculation with *Phytophthora stevensii*, great differences were found within each of the three varietal groups. There was a high correlation between resistance and height, resistance and lateness, and height and lateness within each varietal group. The dent varieties of a certain lateness and height proved no more resistant than sweet and flint varieties of the same lateness and height. It thus appears that resistance in open-pollinated field corn is similar in type and degree to that of the open-pollinated sweet and flint varieties.

Resistance to bacterial wilt of inbred strains and crosses of sweet corn, S. S. IVANOFF and A. J. RIKER (*Jour. Agr. Res. [U. S.]*, 53 (1936), No. 12, pp. 927-954, figs. 3).—The sweet corn tested for resistance to *Phytophthora stewartii* in this study by the Wisconsin Experiment Station included approximately 1,000 inbred strains and 1,000 F₁ hybrids and top crosses of the Golden Bantam type inoculated by artificial puncture or spontaneously infected. The artificial method proved to be more advantageous for resistance tests.

Great differences in resistance were found among the inbred strains, as a rule the taller and later strains showing the greater resistance. The hybrids and top crosses also showed great differences, and their resistance was found to be inherited from the inbred parents. Resistant inbreds usually produced resistant hybrids and susceptible inbreds susceptible hybrids. As a rule, tall and late hybrids were more resistant than short and early hybrids. Hybrids originating from highly resistant inbreds generally showed high resistance regardless of their degree of earliness or lateness. Highly resistant hybrids were commonly late, though a few were early.

Resistance in the hybrids appeared to be generally dominant. Usually the crosses between resistant and susceptible inbreds gave resistant hybrids, crosses between susceptible inbreds and susceptible inbreds gave susceptible hybrids, and crosses between resistant inbreds and resistant inbreds gave resistant hybrids.

Concentration of ammonia necessary in a low-lime phase of Houston clay soil to kill the cotton root-rot fungus, *Phymatotrichum omnivorum*, D. C. NEAL and E. R. COLLINS (*Phytopathology*, 26 (1936), No. 10, pp. 1030-1032).— NH_3 added as NH_4OH to a low-lime phase of Houston clay soil was converted to nitrate fairly rapidly, 30 percent being nitrified after 28 days from applications in excess of 8.25 p. p. m. Therefore, when soils containing cotton root rot mycelium and sclerotia after adding ammonia in graded amounts are tested to determine what concentration is effective in killing the fungus, the concentration of free NH_3 obtained at the time of analysis in cultures where the fungus failed to grow cannot be considered as that effective in killing the fungus. Tests using shorter periods of incubation after treatment are held necessary to determine this. In the experiments here reported the effective initial concentration in the soil appeared to range from 900 to 1,025 p. p. m., in marked contrast to the lower concentrations reported from previous tests.

The organism causing the dry top rot of sugar cane, M. T. COOK (*Jour. Agr. Univ. Puerto Rico [Col. Sta.]*, 21 (1937), No. 1, pp. 85-97, pls. 3).—The morphological, life history, and taxonomic data relating to the causal agent are summarized from the standpoints of the literature and the author's studies, on the basis of which it is believed that "this organism should be kept in the genus *Ligniera* or that there should be a merging of genera as suggested by [B. T.] Palm and [M.] Burk, in which it would become *Sorosphaera rascularum*." The method of infection has not yet been definitely determined. Differences in varietal susceptibility are noted, and the disease is said to be most severe in poorly drained soils. The most important method of distribution from place to place is by the seed cuttings.

Crystalline tobacco-mosaic virus protein, W. M. STANLEY (*Amer. Jour., Bot.*, 24 (1937), No. 2, pp. 59-68, figs. 2).—This is a critical review of previous work on plant viruses (with 72 bibliographic references) and a summary of the author's studies of the virus of tobacco mosaic leading to the following general conclusions: "The fact that the crystalline protein from many different batches of starting material has the same chemical composition, isoelectric point, optical rotation, and biological activity, and that these properties remain constant during many recrystallizations and following drastic fractional crystallization, the fact that it was found impossible to separate the activity from the protein by means of filtration through collodion or other types of filters or by centrifugation of the high molecular weight protein from solution under a variety of conditions, the fact that the destruction spectrum of the virus activity (Duggar and Hollaender, 1934, 1936) [*E. S. R.*, 76 p. 50] agrees essentially with the absorption spectrum of the protein, the homogeneity of the

protein with respect to size and isoelectric point, the isolation of the protein from plants distantly related to tobacco, the isolation of different proteins from plants diseased with different strains of tobacco-mosaic virus, and the fact that any change in the protein is accompanied by a change in virus activity are all indications that the virus activity is a property of the protein."

Since tobacco-mosaic virus has long been considered a representative virus, it seems likely that other viruses will be found to be proteins, and in view of the properties which this protein possesses the border line between the living and the nonliving tends to become nonexistent. It very possibly represents "a link between the type of organization within the atom or molecule with which chemists have concerned themselves and the type of organization within the cell with which biologists have been concerned. In any event, it now appears possible to list protein molecules along with living organisms, such as bacteria, fungi, and protozoa, as infectious disease-producing agents." These diseases may thus be regarded as disruptions of the normal metabolism caused by the production of virus protein.

Frenching of tobacco and thallium toxicity, E. L. SPENCER (*Amer. Jour. Bot.*, 24 (1937), No. 1, pp. 16-24, figs. 2).—When the toxic action of 33 different chemical elements on young seedlings of *Nicotiana tabacum* var. Turkish was studied, thallium was the only one that produced chlorosis in the youngest leaves and formed strap-shaped leaves resembling those in frenching. It produced chlorosis in tobacco in amounts as low as 0.007 p. p. m. in nutrient water cultures, 0.10 p. p. m. in sand, 0.38 p. p. m. in orchard soil (a light, sandy, nontoxic loam), and 0.25 p. p. m. in field soil (a heavy, clay loam which causes severe frenching). Thallium was more toxic to seedlings in sand when added with a water extract of this field soil than when added with the orchard-soil extract or with water alone. Although a water extract of the orchard soil in itself was nontoxic, the addition of a nontoxic concentration of thallium rendered it toxic, supplementing the activity of some principle already present in the soil (possibly thallium) sufficiently to produce chlorosis.

Species of *Nicotiana* susceptible to frenching were also found to be sensitive to thallium, and vice versa. Thallium-induced chlorosis was controlled by the addition of nitrogen salts, aluminum sulfate, and potassium iodide, all of which are effective in preventing frenching.

The evidence indicates a striking similarity between natural frenching and thallium toxicity in the symptoms they produce on Turkish tobacco and also with regard to the methods by which they are controlled. Final proof that these two diseases are identical requires the demonstration of the presence of toxic quantities of thallium in soils which produce frenching. At present it is questionable whether the known chemical methods are sufficiently sensitive to detect such small traces of thallium as these experiments have indicated must be present in the soil if frenching is a thallium-toxicity disease.

A strain of the virus which causes streak in tomato, G. H. BECKLEY (*Canad. Jour. Res.*, 14 (1936), No. 12, Sect. C, pp. 419-424, pls. 3).—"In this paper the symptoms of a strain of tomato streak virus 1 found in Ontario are described and are compared with those produced by tomato streak virus 1 and tobacco virus 1 on the same hosts. On tobacco, variety White Burley, Adecock, etc., the Ontario strain produces necrotic local lesions on rubbed leaves followed by systemic mottling, whereas tomato streak virus 1 generally produces necrotic local lesions only, though sometimes systemic necrosis may follow. Also, on *Nicotiana glauca* the Ontario strain gives rise to systemic mottling with necrosis following the primary necrotic local lesions, whereas

tomato streak virus 1 produces primary necrotic local lesions with or without systemic necrosis.

"The fact that all varieties of tobacco do not react in a similar manner to either tomato streak virus 1 or the Ontario strain is shown by a comparison of symptoms on Harrow Velvet (systemic mottling only) and White Burley or Kelley (necrotic local lesions sometimes followed by systemic necrosis). On the other hand, all varieties tested respond to inoculation with tobacco virus 1 (tomato mosaic) by production of systemic mottling with some distortion. A series of inoculations on seven varieties of tobacco grown in the field has shown that *N. tabacum* varieties Adcock, Gold Tip, White Burley, and Greenwood were killed within 2 weeks after inoculation with tomato streak virus 1, whereas the Ontario strain on the same varieties caused stunting with systemic mottling of leaf tissue but did not kill the plants.

"Tests as to reaction to aging and heat have demonstrated that tomato streak virus 1, the Ontario strain of this virus, and tobacco virus 1 have similar properties in that each is viable after 6 months' aging and each is rendered inactive after 10 min. at 90° C. Immunity tests show that tobacco virus 1 immunizes plants against infection with either tomato streak virus 1 or the Ontario strain of this virus. It is suggested, therefore, that tomato streak virus 1 and the Ontario strain of the virus may be strains of tobacco virus 1."

A possible new wilt disease of tomatoes, O. A. REINKING (*Farm Res. [New York State Sta.]*, 3 (1937), No. 3, pp. 12, 13, fig. 1).—Studies (including successful inoculations) of a wilt disease observed in the hot, dry season of 1936 in the Rochester tomato area indicated it to be due to a new fungus differing from the ordinary *Fusarium* of tomato wilt and here given the provisional name *F. bulbigenum lycopersici* f. 1.

The effect of certain cultural and handling practices on the resistance of apples to *Penicillium expansum*, K. F. BAKER and F. D. HEALD (*Phytopathology*, 26 (1936), No. 10, pp. 932-948).—In tests at the Washington Experiment Station in which over 9,000 sound fruits were uniformly punctured, immersed in a suspension of blue mold spores, and stored at approximately 0° C., the rate of rot advance in Delicious and Winesap apples was slightly greater in fruit from fertilized than from unfertilized trees and in fruit picked at prime maturity than at early maturity. When fruit was coated with a paste of *P. expansum*-decayed apple pulp, then wrapped in oiled paper before storing, the number of lenticel infections per apple was greater in fruit picked at prime maturity than at early maturity, the Winesap showing more resistance to lenticel infection, as well as to spread in the flesh, than the Delicious. Fertilizer did not affect lenticel infection. The Jonathon variety developed more lenticel infection than the other two.

Recent investigations on the control of cedar-apple rust in the Hudson Valley, J. M. HAMILTON (*New York State Sta. Bul.* 678 (1937), pp. 34, figs. 8).—Brief reviews are given of the life histories of the fungi of apple rust (*Gymnosporangium juniperi-virginianae*), hawthorn rust (*G. globosum*), and quince rust (*G. clavipes*) as pertaining to an appreciation of the rust problem on apples in the Hudson Valley. The relative importance and status of these species for apple production in this area are considered. The danger from foliage infection by the apple rust fungus extends from the first of May to the latter part of June, and for apple fruit infection, for the most part, over the month of May.

The data presented are limited to field control trials for the apple rust fungus, data being recorded by infection periods. Commercial control was obtained

economically by fungicides and absolute control where no growth occurred between the spray application and the infection period. Lime-sulfur (1-100) gave commercial control. All wettable sulfurs gave satisfactory control under average conditions, but under adverse conditions those depositing the greatest sulfur residue were the most effective. Flotation sulfur in the paste form and sulfurs plus amendments to promote adhesiveness appeared most promising. The finer sulfurs (particle size of 5μ or less) that spread well and had but little run-off were most effective, depending partly on the concentration. Bordeaux mixture (2-3-100) was effective, but two proprietary copper substitutes, at the concentrations used, were not. Timeliness and thoroughness were obviously vital factors and apparently were more important than the concentration of the materials.

Suggestions are given for adapting the experimental results to commercial practice, especially for combined apple rust and scab control. Where effective spray equipment is unavailable and the alternate host cannot be reduced to a minimum, substitution of rust-resistant varieties of apples is recommended.

Mottle-leaf and sun-blotch disease control, E. R. PARKER (*Calif. Avocado Assoc. Yearbook, 1936, pp. 149-151*).—Tests at the California Citrus Experiment Station have shown that spraying with zinc compounds gives a favorable response in avocado trees affected with mottle-leaf. Sun-blotch of avocado trees is shown to be a virus disease capable of propagation by budding and grafting, but no evidence of other means of propagation has thus far been found. Preventive measures are outlined. As to pruning methods, the likelihood of success appears to depend on the amount of affected tissue and the severity of the pruning necessary.

Sweet orange fruit scab caused by *Elsinoë australis*, A. A. BITANCOUET and A. E. JENKINS (*Jour. Agr. Res. [U. S.], 54 (1937), No. 1, pp. 1-18, pls. 13, fig. 1*).—Sweet orange fruit scab, as yet identified only in South America, affects the following varieties of *Citrus sinensis*: Abacaxi, Bahia Navel, Criolla, Lima, Mangaratiba, Pera, Ruby Blood, Sabará, Selecta, Santos, São Sebastião, Sweet Mediterranean, and Valencia. Other kinds of citrus affected are the tangerine of Brazil (*C. nobilis* var.), a sweet lime known as "lima da Persia" (*C. aurantifolia*), a sour lime known as "limão seda" (*C. aurantifolia*), "laranja cravo" (*Citrus* sp., probably a variety of *C. nobilis*), and a pointed-leaf papeda (*C. hystrix?*), the last two named being also susceptible to sour orange scab. The disease has been identified from Argentina, Paraguay, Uruguay (apparently), and Brazil, where it is found more or less widely distributed in the States of São Paulo, Rio Grande do Sul, Rio de Janeiro, Minas Geraes (one locality), and in the Federal District. The earliest records are from Paraguay (1882), São Paulo (1900, apparently), and Rio Grande do Sul (1923). The disease, which may be controlled by spraying, is of economic importance particularly because it blemishes the fruit. It affects the leaves and twigs more rarely. In its symptoms (described) it has the general aspect of our "sour orange scab" caused by *E. fawcettii*, although there are appreciable differences in the lesions.

The taxonomy of the perfect and imperfect stages of the fungus has been previously noted (E. S. R., 76, p. 498). Saltations may be produced, and these have been isolated and cultured separately. At constant temperatures between 35° and 39.5° C., both *E. australis* and *E. fawcettii* grew from 9.5° to 35°, the optimum for *E. australis* occurring at 24.5°-29° (probably being near 26°) and for *E. fawcettii* at 20°-24.5° (probably near 21°). In inoculation experiments, *E. australis* from sweet orange gave positive results on sweet orange, tangerine, and laranja cravo and was reisolated. *E. fawcettii* infected laranja

cravo and sour orange, but not sweet orange. Cross-inoculations on citrus with *Sphaceloma perseae* and on avocado with *E. fauconneti* and *E. australis* gave negative results.

A disporous *Gnomonia* on pecan, J. B. DEMAREE and J. R. COLE (*Phytopathology*, 26 (1936), No. 10, pp. 1025-1029, figs. 2).—In Georgia and Florida a *Gnomonia* produces necrotic spots on living leaves of the pecan (*Hicoria pecan*), the lesions first appearing in June and mature perithecia about 1 mo. later. Two spores are commonly formed in each ascus, but occasionally one, and less often three or four. A conidial stage has not been observed. The fungus is considered only a minor one on pecans and is frequently associated with rosette, a zinc-deficiency disease. To distinguish this species of *Gnomonia* from others reported on *Hicoria*, two of which cause destructive diseases of pecans, the name *G. dispore* n. sp. is proposed. It was observed on other species of *Hicoria*. In pure culture it developed typical perithecia, asci, and ascospores.

Leaf blight of China aster caused by *Rhizoctonia solani*, A. J. ULLSTRUP (*Phytopathology*, 26 (1936), No. 10, pp. 981-990, figs. 3).—A culture of *R. solani* was isolated from severely blighted leaves of China-asters growing in New Jersey under greenhouse conditions. A comparative study was made between this isolate and one from potato and three from sugar beets. The isolate from China-aster could be differentiated from other isolates on the basis of more rapid growth rate at 35° C., growth on certain agar media, and its high pathogenicity on various host plants. The culture obtained from China-aster, together with one isolate from sugar beet, penetrated directly uninjured cuticularized epidermal cells, while other isolates penetrated only through stomata or not at all. Cross-inoculations indicated no marked host specialization between the different isolates.

Rhododendron wilt and root rot, R. P. WHITE (*New Jersey Stat. Bul.* 615 (1937), pp. 32, figs. 18).—Rhododendron wilt, caused by *Phytophthora cambivora* (= *P. cinnamomi*) is reported to be the most serious disease of juvenile rhododendrons known. *Rhododendron ponticum*, widely used as an understock for grafting, is the most susceptible species tested, although none of the natives were resistant to inoculations.

Yellowing of the foliage, wilting, decay of roots, and brown, sunken cankers on the current season's growth are characteristic. The phloem and cambium are invaded in stems older than 1 yr., but the xylem is not invaded until after the plant dies. On current season's growth the fungus spreads inter- and intracellularly into the cortex, through the medullary rays and into the pith, and out the leaf petioles into the lamina of the leaf.

Inoculations were successful through roots, growth cracks in the basal portion of stems, uninjured lower surfaces of leaves, and through injuries to above ground stem parts. On the basis of the pathogenicity tests, there seem to be three distinct strains of the fungus. An optimum temperature of 25°-27.5° C. held for all strains, but one isolate showed a consistently greater tolerance to high (35°) and low (5°) temperatures than all others. The rhododendron isolate had a tolerance to acidity of pH 4.25+. *R. ponticum* has shown better growth at pH 4.25 than at lower acidities. In highly organic soils *R. ponticum* grows most rapidly when the soil is adjusted to 60-70 percent of its water-holding capacity. Disease prevalence is greater in soils of higher soil moisture contents, first evidences of wilt due to inoculation of the roots occurring on plants growing in soils kept above 70 percent of their water-holding capacity. Except for one isolate, the fungus was killed by long ex-

posures to low winter temperatures normally experienced at 4- and 6-in. soil depths at New Brunswick. Soil known to be infested was freed by exposure to the same temperatures.

Control may be effected by strict daily roguing of field frames, avoiding excess irrigation, providing proper soil acidity for growth of the host, preventing root decline due to becoming pot-bound, providing partial shade and mulch for young plants, and allowing the outdoor soil to freeze as deeply as possible during winter.

Cephalosporium wilt of elms, D. B. CREAGER (*Natl. Shade Tree Conf. Proc.*, 12 (1936), pp. 140-144).—Since June 1934 this wilt or die-back has been studied intensively at the Arnold Arboretum. The symptoms are described. The causal fungus produces naked spore heads of the *Cephalosporium* type and pycnidia characteristic of *Dothiorella*, to which it has been referred as *D. ulmi*. Entrance of the fungus commonly takes place through wounds made by leaf-eating insects. Overwintering pycnidia in the bark of dead branches produce abundant viable spores the following spring.

Recommended control measures comprise the exclusion of infected trees from plantings and nurseries, careful pruning of light infections, eradication of all bad cases, and protection from injuries as far as possible by combined fungicidal-insecticidal sprays.

Verticillium root disease of American elms, L. R. TETON and H. L. JACOBS (*Natl. Shade Tree Conf. Proc.*, 12 (1936), pp. 128-139, fig. 1).—A disease of American elms regarded as a native disease, characterized by distinctive symptoms and always resulting in the death of affected trees, has been known in the Ohio Valley for some years prior to 1927. It appears to occur always on ground once forested, and in soils at pH 8.0. *V. rhizophagum* was the fungus most consistently isolated from samples of roots from 12 affected trees. Reinoculations with this fungus indicated its ability to induce stunting and death of seedlings grown directly from seeds in test tubes and to reproduce the entire series of symptoms of the spontaneous disease in young potted elms under controlled conditions. Anatomical and histological studies showed essentially a parasitization and destruction of the most newly formed xylem, of the cambium, and of the newest phloem. The effect is in the nature of a root rot not to be confused with any of the wilt diseases. Treatments tending to stimulate new root growth and to establish a somewhat higher soil acidity proved futile.

The dissemination of *Septoria acicola* and the effect of grass fires on it in pine needles, A. F. VERRALL (*Phytopathology*, 26 (1936), No. 10, pp. 1021-1024).—Evidence from spore traps and from disease development on seedlings of *Pinus palustris* protected and unprotected from rain splashing from diseased seedlings in an epidemic area in Louisiana indicated that this needle blight of pine seedlings is chiefly disseminated by splashing raindrops. Heat from grass fires sufficient to kill leaf tissue was found to kill the *Septoria* in that tissue.

ECONOMIC ZOOLOGY—ENTOMOLOGY

Some changes in the soil fauna associated with forest fires in the longleaf pine region, F. HEYWARD and A. N. TISSOT (*Ecology*, 17 (1936), No. 4, pp. 659-666, fig. 1).—Observations of animal signs and counts of the microfauna reported in this contribution from the U. S. D. A. Southern Forest Experiment Station and the Florida Experiment Station cooperating show that "the A. horizon of soils supporting dense, long-unburned longleaf pine forests offers an excellent habitat for a diversified soil fauna. This is in contrast with

pine forests subjected to frequent fires, in which, instead of an A_o horizon, a ground cover of herbaceous plants is present. Soils of unburned areas were riddled with holes and tunnels of small mammals and insects, a condition generally lacking on frequently burned areas. The A_o horizon of unburned areas contained approximately 5 times as many microfaunal forms as the ground cover of burned areas. The top 2 in. of mineral soil of unburned areas contained 11 times more such animals than the corresponding soil depth from burned areas. In general, the same microfaunal groups were found in soils protected from fire as in soils exposed to periodic fires, although the total number in each was different. In general, earthworms were more numerous in soils from unburned areas. Mites were by far the most abundant group of microfauna, 98 percent of the animals in the soil from unburned areas belonging to this group. The diversified active soil fauna of the unburned areas is believed to be responsible for the penetrable and well-aerated soil typical of such areas. This is in striking contrast to the more compact, less porous soil of frequently burned areas in which animal activity is much less abundant."

Food habits of Iowa red foxes during a drought summer, P. L. ERRINGTON (*Ecology*, 18 (1937), No. 1, pp. 53-61).—Comparisons made by the Iowa Experiment Station of the food habits of red foxes (*Vulpes fulva*) in Iowa during the drought season of 1934 and the normal season of 1933, here presented, are based upon data obtained from the examination of 1,010 food items and 1,175 fecal samples from 113 breeding dens in 1933 (E. S. R., 74, p. 63) and 2,848 food items and 935 fecal samples from 200 dens in 1934. "From this material, the conclusion may be drawn that, of the chief types of food, the representation of rabbits, ground squirrels, passerine birds, and ring-necked pheasants was nearly the same in 1934 as in 1933; that the representation of mice dropped appreciably in 1934, coincident with a rise in representation of pocket gophers, domestic chickens, and insects (mainly such Coleoptera as *Phyllophaga*)."

Food habits of the red fox in Iowa: Management depends to a great extent on what fox eats, P. L. ERRINGTON (*Amer. Wildlife*, 26 (1937), No. 1, pp. 5, 6, 13, fig. 1).—A practical contribution based upon the work above noted.

A study of the winter activities of the mink, W. H. MARSHALL (*Jour. Mammal.*, 17 (1936), No. 4, pp. 382-392, figs. 3).—A report is made of studies of *Mustela vison mink* conducted in Washtenaw County, Mich., during the months of December 1934 and January, February, and March 1935. The details are presented in tables and figures.

An ecological study of the mole, A. V. ARLTON (*Jour. Mammal.*, 17 (1936), No. 4, pp. 349-371, figs. 5).—A study of the ecology of the mole, commenced in the eastern part of Iowa and continued in the vicinity of Lincoln, Nebr., is presented at some length, details being given in tables and figures. The contribution is presented with a list of 29 references to the literature.

The house rat, J. SILVER (*U. S. Dept. Agr. Circ.* 423 (1937), pp. 19, figs. 15).—A practical account is given of the house or brown rat, its breeding and other habits, abundance, economic status, relation to health, and means of control.

Moisture and its relation to the cone-storing habit of the western pine squirrel, W. T. SHAW (*Jour. Mammal.*, 17 (1936), No. 4, pp. 337-349, figs. 7).—An account based upon observations of species of *Sciurus* in western United States and a review of the literature is presented.

Food habits of a weasel family, P. L. ERRINGTON (*Jour. Mammal.*, 17 (1936), No. 4, pp. 406, 407).—Observations of food habits of the weasel, probably *Mustela longicauda*, in Ruthven, Iowa, considered to give a fair idea of the

midsummer food habits of this weasel under the environment indicated, are briefly reported in this contribution from the Iowa Experiment Station.

American bird biographies, A. A. ALLEN (*Ithaca, N. Y.: Comstock Pub. Co., 1934, pp. IX+238, pls. 20, figs. 190*).—The life and habits of some 20 representative American birds are dealt with. The work includes 10 color plates and 10 wash drawings by G. M. Sutton.

The birds of Minnesota, I, II, T. S. ROBERTS (*Minneapolis: Univ. Minn. Press; London: Oxford Univ. Press, 1936, 2. ed., rev., vols. 1, pp. XXVI+718, pls. 50, figs. [305]; 2, pp. XVII+850, pls. 42, figs. 308*).—This is said to be a thorough revision (*E. S. R.*, 68, p. 64), new material bringing the work as nearly up to date as possible. Minor changes, such as dates of migration and nesting, have been inserted in the original text. More extensive alterations and new material have been added in the form of an appendix to each volume, textual references being made to all such changes and additions. The pagination has been continued through the appendixes. The general index at the end of the second volume has been completely rewritten.

The thrushes and mimids of New Jersey, L. A. HAUSMAN (*New Jersey Stat. Bul. 618 (1937), pp. 32, figs. 28*).—This, the ninth in the series of birds native to New Jersey and found generally distributed over the northeastern part of the United States (*E. S. R.*, 75, p. 511), treats of eight native thrushes and of the catbird, brown thrasher, and mockingbird of the family Mimidae (referred to as mimics or mimids), which are closely allied in structure. A chart comparing the dietaries of the six thrushes of the genus *Hylocichla*, a chart of their chief foods, a figure showing their breeding grounds in northeastern North America, and a plate illustrating the six species are included. Wild fruits, beetles, ants, and caterpillars are their principal food supply.

Ancient records of birds from the island of St. Croix, with observations on extinct and living birds of Puerto Rico, A. WETMORE (*Jour. Agr. Univ. Puerto Rico [Col. Sta.], 21 (1937), No. 1, pp. 5-16, pl. 1*).—Twenty-three species of birds identified from bones in a kitchen midden excavated on St. Croix in the Virgin Islands during the summer of 1934 are reported upon, supplemented by information on Puerto Rican forms. A description of one new species is included.

Studies of the nesting activities of Latimer's vireo (*Vireo latimeri* Baird), N. G. SPAULDING (*Jour. Agr. Univ. Puerto Rico [Col. Sta.], 21 (1937), No. 1, pp. 17-28, pls. 3*).—Observations of the nesting activities of *V. latimeri*, made at Algarrobo on the north coast of Puerto Rico, are reported. The data given relate to its song, call notes, territorial occurrence, nest, eggs, incubation, rearing of young, and the behavior of the male upon destruction of mate and young.

The development of the giant Surinam toad (*Bufo marinus* L.), F. SEIN, JR. (*Jour. Agr. Univ. Puerto Rico [Col. Sta.], 21 (1937), No. 1, pp. 77, 78, figs. 3*).—A tadpole, from a strand of eggs of the giant toad collected in a brook at Monacillos, Rio Piedras, P. R., on April 20, 1934, developed to the adult stage on October 3, 1934, a period of nearly 6 mo. from collection.

What the giant Surinam toad (*Bufo marinus* L.) is eating now in Puerto Rico, G. N. WOLCOTT (*Jour. Agr. Univ. Puerto Rico [Col. Sta.], 21 (1937), No. 1, pp. 79-84*).—A comparison is made of the food habits of the giant toad based upon studies of the contents of pellets of excrement collected in 1935 and 1936 with the findings of Dexter (300 toads from 18 localities) in 1931 (*E. S. R.*, 70, p. 357), at a time when the toad had presumably attained its maximum abundance in Puerto Rico. It is concluded that, while no decided change in the food of this toad has occurred in recent years due to the increasing

scarcity of May beetles resulting from its activities, the even greater scarcity of some of the other insects and other animals previously eaten leads to an even more exclusive selection of the adults of white grubs for its food. Thus the introduction of this toad into Puerto Rico for the control of white grubs was not only an immediate and temporary success, but tends, at least so far as the food habits of the toad determine its trend, continually to become more effective and more permanent.

On the potential longevity of various helminths with a record for a species of *Trichostrongylus* in man, J. H. SANDGROUND (*Jour. Parasitol.*, 22 (1936), No. 5, pp. 464-470).—In his treatment of this subject, the author considers trematodes, cestodes, and nematodes.

Studies on the endoparasitic fauna of Trinidad mammals.—IV, Further parasites from Trinidad deer, T. W. M. CAMERON (*Canad. Jour. Res.*, 14 (1936), No. 11, Sect. D, pp. 165-167, fig. 1).—In this continuation (E. S. R., 75, p. 654) of the author's studies, the trematode *Paramphistomum cotylophorum* is recorded from the Trinidad deer *Mazama simplicicornis*, and the female of the nematode *Encyathostomum longesubulatum* from the deer is described.

On the fourth stage larva of *Chabertia ovina*, H. J. GRIFFITHS (*Canad. Jour. Res.*, 14 (1936), No. 11, Sect. D, pp. 168-171, figs. 5).—The structure of the early fourth-stage larva of *C. ovina*, an important nematode parasite of ruminants, is described in detail.

Experimental studies of factors influencing the development of the eggs of pig ascarid (*Ascaris suum* Goeze), G. C. HUFF (*Jour. Parasitol.*, 22 (1936), No. 5, pp. 455-463, figs. 2).—The author found that while the removal of the albuminous coating characteristic of the eggs of ascarids has no visible effect on development of ova at 30° C., it makes possible the development at 38° of 87 percent of the eggs through the tadpole stage and about 11 percent of the eggs to become embryonated. It is concluded that the role of the development of albumin is underestimated, since it modifies oxygen uptake significantly at optimum temperatures and is at least partially responsible for failure of the eggs to develop at temperatures around 38°.

General entomology, R. A. WARDLE (*Philadelphia: P. Blakiston's Son & Co.*, 1936, pp. VII+311, figs. 96).—An elementary text.

Studies on the freezing process in insects, R. W. SALT (*Minnesota Sta. Tech. Bul.* 116 (1936), pp. 41, figs. 3).—The importance of low temperatures in limiting the distribution and abundance of insects which must undergo a period of hibernation led to a study of some of the more fundamental problems of insect freezing, particularly with a view to clarifying the physical concepts involved. The insects used in the experimental work, representative of several types, were found to exhibit a considerable variation in the effect that desiccation or other change in water content has on their undercooling points. Puparia of the housefly lost 4 percent of their weight when exposed to warm, dry laboratory conditions for several hours, while their undercooling points dropped from -12° to -22° C. Adults of the boxelder bug, desiccated over calcium chloride at 2° and 20°, lost over 20 percent of their weight, while the undercooling points remained stationary. Larvae of the Mediterranean flour moth had almost the same percentage water content whether they were last instar feeding larvae, early prepupal larvae, or prepupal larvae from cocoons, yet the undercooling points averaged -5.5°, -8°, and -21.3°, respectively. Hibernating Say's stinkbug increased in water content from 53 to 67 percent of their total weight when fed for 5 days, but the undercooling points remained unchanged.

The effects of moisture in contact with the body surface, usually in the form of ice, and the need for careful technic to eliminate this factor when not desired are pointed out. Contact moisture reduces and sometimes completely eliminates undercooling in many insects, while others are not affected by even a heavy coating of water or ice. The factors governing the action of contact moisture appear to be the extent and "quality" of the contact, the type of integument of the insect, and probably others. Soft-bodied insects such as dipterous and lepidopterous larvae are usually susceptible, although the heavily sclerotized wasps, *Polistes*, are also very susceptible to ice crystal inoculation. Larvae of *Lucilia sericata*, the housefly, the Mediterranean flour moth, the Indian meal moth, and *Phyllophaga* are all readily inoculated by contact moisture. The pupae are slightly harder to inoculate, exhibiting an apparent individual variation which probably depends more on the quality of the contact than on the insect. Eggs seem to be very resistant, those of the clear-winged grasshopper and the Angoumois grain moth were entirely so in spite of all efforts to inoculate them. Fully developed larvae of the forest tent caterpillar in the eggshell were also proof against inoculation. Larvae of *Eurycephalomys myopaeformis*, on the other hand, exhibited a doubtful or very low susceptibility.

Three species of stored-product pests, Mediterranean flour moth, Angoumois grain moth, and black carpet beetle, were tested for the location of their minimum lethal temperatures. The variation of these temperatures is given in the form of maximum, minimum, and mean lethal low temperatures. The complete life cycle of *Ephestia*, most of the stages of *Sitotroga*, and the larvae, pupae, and adults of *Attagenus* were studied. A temperature of -27° kills all stages of *Ephestia*, and -27.5° all stages of *Sitotroga*. The most resistant stage in each case is the newly hatched unfed larva. The first feeding of these larvae lessens their cold resistance so effectively that they are then in the least resistant stage. There seems to be evidence that this is a rather general phenomenon in insects, at least of certain types. The forest tent caterpillar behaves similarly. The food ingested by the newly hatched larvae of this species as they chew their way out of the eggshell raises their undercooling points more than 20° . It is suggested that this may give important clues in investigations on the factors involved in undercooling, whether such investigations are of a biological or physical nature. The quantity factor of cold, effective on many insects infesting stored products, was tested with the object of determining whether it could act in a short enough period of time to affect experiments designed for the study of the intensity factor alone.

In the case of insects that can withstand freezing, the minimum lethal temperature is lower than the undercooling point and may be very simply determined by test exposures. For insects that are killed by freezing, the undercooling point is the all-important minimum lethal temperature. If the insect is dry or immune to inoculation by contact moisture, then it is the normal undercooling point that is important. If the insect is inoculated by contact moisture, undercooling is limited, and a new and higher undercooling point is observed. The location of this new point is dependent on many factors, and may even coincide with the freezing point, in which case undercooling is nil. In any case it becomes the minimum lethal temperature for that particular insect.

Bushland (ET-88); A Graphite Stamp Pad for Temporary Marking, by C. E. Woodworth (ET-89); An Inexpensive Hot-Wire Glass Cutter, by R. A. Fulton (ET-90); An Agar-Sugar Preparation Used as Food in Parasite Shipping Cages, by J. K. Holloway (ET-91); A Pressure Sprayer for Handling Small Quantities of Material, by G. W. Barber (ET-92); and An Improved Apparatus for Mixing Insecticidal Dusts, by T. E. Bronson (ET-93).

Technique for rearing subterranean insects, H. R. Beyson (*Jour. Kans. Ent. Soc.*, 9 (1936), No. 3, pp. 73-84, pl. 1).—In this contribution from the Kansas Experiment Station the problem of rearing insects which spend a portion or all the stages of their life cycles beneath the surface of the soil is dealt with. The contribution is presented with a list of 18 references to the literature.

The biological control of insects (with a chapter on weed control), H. L. SWEETMAN (*Ithaca, N. Y.: Comstock Pub. Co., 1936, pp. XII+461, [pl. 1], figs. [147]*).—This work, with a foreword by L. O. Howard, deals with the subject as follows: The theoretical basis of biological control (pp. 1-27); the use of (1) resistant hosts (pp. 28-41), (2) micro-organisms—bacteria and fungi (pp. 45-76) and viruses and protozoa (pp. 77-96), (3) parasitic invertebrate animals—Nemathelminthes (pp. 97-109) and Hexapoda (pp. 110-176), and (4) predatory invertebrate animals—Arachnida and Hexapoda (pp. 177-217); some biological relations of insect parasites and predators to their hosts (pp. 218-257); factors to be considered in the utilization of insect parasites and predators (pp. 258-288); the introduction of insect parasites and predators (pp. 289-317); the use of predatory vertebrate animals (pp. 318-339); the results of biological

control experiments against animals (pp. 340-358); and the biological control of pest plants (pp. 359-383). A glossary (pp. 384-389) and a list of references arranged alphabetically by chapters (pp. 390-420) are included.

Plant protection by the aid of therapeutants, G. H. CUNNINGHAM ET AL. (*Dunedin, New Zeal.: John McIndoe, 1935, pp. XXVI+243, pls. 4, figs. 23*).—Section 1 of this work deals with sprays and spraying (pp. 1-84), section 2 with dusts and dusting (pp. 85-94), section 3 with fumigants and fumigation (pp. 95-127), section 4 with disinfection of seeds, tubers, bulbs, and corms (pp. 128-152), section 5 with soil disinfection (pp. 153-176), and section 6 with miscellaneous measures (pp. 177-194). A glossary of terms, a bibliography of 26 pages, and a general index are included.

A study of arsenical dusting of cabbage in relation to poison residues, C. E. SMITH, W. J. REID, JR., P. K. HARRISON, and C. O. BARE (*U. S. Dept. Agr. Circ. 411 (1937), pp. 8, fig. 1*).—The results of 12 experiments, 6 in Charleston, S. C., and 6 at Baton Rouge, La., during the seasons of 1932-33 and 1933-34 to determine the limitations imposed by residue on treatments with arsenicals in controlling worms on cabbage are reported, the details being given in 4 tables. Four dilutions of paris green and calcium arsenate and one of lead arsenate, using lime as a diluent, were employed in two or more of the experiments. "The rates per acre per application ranged from approximately 10 to 24 lb., the number of applications of the different insecticides ranged from 0 to 10, and the periods of time from last dusting to sampling ranged from 8 to 100 days. The samples for residue determination consisted of from 10 to 20 plants taken at random from each treatment and trimmed to conform to U. S. grade No. 1—except in one experiment in which the entire leaf growth was included for analysis, the stalks being cut just below the bottom leaf. The studies were conducted under various conditions of rainfall, temperature, and soil, and with three plant varieties."

It was shown that, "with intervals up to 30 days from the last arsenical application to marketing, cabbage may retain arsenical residues exceeding the legal tolerance of 0.01 grain of arsenic trioxide per pound of marketable product. The loose leaves surrounding the compact head carry the principal portion of these residues. The variety of cabbage and the quantity of rainfall also affect the residues of the harvested product. Excessive residues were found in these tests in nearly all instances where the samples were taken within 10 days after the last application of the arsenicals was made, in about 30 percent of the samples examined after about 20 days, but in less than 10 percent of the samples taken after 24 to 30 days. For periods of time exceeding 30 days no excessive residues were found during the course of these tests." The data obtained indicate that it is unsafe to apply arsenicals on cabbage after foliage becomes exposed that will be a part of the marketed product.

Toxicity of fruit sprays: A study of lead spray residues in Iowa-grown fruit, with reference to manifestations in consumers, R. H. HEEBEN and H. B. FUNK (*Pub. Health Rpts. [U. S.], 52 (1937), No. 1, pp. 8-16*).—Report is made of a case of arsenic dermatitis in an individual who consumed apples covered with heavy spray residues. Examinations for lead in spray residues on Iowa apples of the 1935 crop showed a lead content generally below the maximum allowed by Federal regulations for apples entering into interstate commerce, although a higher lead content was found in two lots from Iowa orchards.

"Imported apples which were examined also showed a lead content much lower than the maximum amount permitted by interstate commerce regulations, with the exception of one lot from an Illinois orchard. Tests on apples from orchards receiving light sprays, as are customary in Iowa, show lower lead

determinations than do crops from districts receiving heavier sprays. The lack of increase of basophilic substances in the red blood corpuscles of individuals who ate sprayed apples regularly indicates that the amounts of lead ingested were not sufficient to produce signs of toxicity."

A list is given of 13 references to the literature.

Investigation of organic compounds as insecticides, H. G. GUY (*Delaware Sta. Bul. 206 (1937), pp. 60, figs. 10*).—The need for an effective substitute for lead arsenate nontoxic to man and the higher animals led to the work here reported. Continued through 3.5 yr., it resulted in the evaluation of approximately 1,000 compounds, some 800 of which were tested as stomach poison insecticides.

"In laboratory tests, representatives of five different chemical groups, namely, phosphoniums, coordinated chromium salts, thiazines, thiuram sulfides, and thiocarbamates, approached the efficiency of lead arsenate in insect control. Although several other compounds were comparable in toxicity to this insecticide, they injured plant foliage severely. Under Delaware field conditions, on the contrary, only the thiuram sulfides gave excellent insect control. (The thiocarbamates and phosphoniums have not been so tested.) The other compounds, in particular the thiazines, through possible modifications in their physical and chemical properties, may still be of commercial value as insecticides against specific insects on certain crops."

Thiuram sulfides act as repellents to chewing insects. Tetramethylthiuram monosulfides and tetramethylthiuram disulfide were more effective in this respect than either lead arsenate or hydrated lime, both in the laboratory and in the field. They should be of commercial value as repellents for the adult Japanese beetle, since they give excellent protection of foliage from attack by this insect without creating a conspicuous spray residue.

Observations on the effectiveness of some moth-proofing, chemical compounds, D. R. MUSSEY (*Jour. Kans. Ent. Soc., 9 (1936), No. 4, pp. 116-125*).—Experimental work conducted with a view to determining the insecticidal values of various moth-proofing compounds, most of which are now used in some form or another against insects injurious to fabrics and were tested for control of the case-making and the webbing clothes moths and the black, common, and varied carpet beetles, is reported upon, the details being given in table form.

The results indicated that all of the compounds tested offer approximately complete protection to the treated fabrics against clothes moths and carpet beetles. In many cases this protection either caused directly the death of the insects confined within the treated samples or resulted in their starvation. Dry cleaning and washing removed a sufficient portion of the Steuben Chemical Compound and the sodium fluosilicate from the fabrics to permit the larvae to cause appreciable damage to them. Similar tests were not conducted with the other moth-proofing compounds used. The results of the dry cleaning and washing tests appear to indicate that guarantees or claims of protection for the life of the fabrics from clothes moths or carpet beetles upon one application of any particular moth-proofing compound are to be looked upon with suspicion. Complete immersion of the fabrics gave slightly better protection than the application of the moth-proofing solution as a spray. The application of moth-proofing solutions by means of immersion or with the aid of a power spraying machine is recommended. Fabrics of the finished type were damaged in the checks to a greater extent than the fabrics of the unfinished type.

"The toxic moth-proofing materials, which consist of the arsenical and fluorine compounds, usually killed the larvae of these clothes pests when feeding occurred. Although the moth-proofing solutions which contain an arsenical

compound are used very extensively at the present time by several moth-proofing concerns, these solutions should be applied with caution due to their toxic effects upon human beings.

"Larvae of the clothes moths were killed more quickly by the moth-proofing compounds tested than were the larvae of the various species of carpet beetles, the latter being apparently more resistant to the toxic or repellent effects of these compounds.

"From the results of the experiments, it appears that the general public could advantageously purchase sodium fluosilicate in bulk, prepare a saturated solution in distilled water, apply it thoroughly either by immersion or spraying, and obtain a high degree of success in the protection of clothing and carpets against these fabric pests."

Fall clean-up measures against scale insects and whitefly, J. B. WATSON (*Citrus Indus.*, 17 (1936), No. 10, pp. 18, 19).—This is a practical contribution from the Florida Experiment Station.

Department of entomology, S. G. JARY and M. D. AUSTIN (*Jour. Southeast. Agr. Col., Wye, Kent. Nos.* 37 (1936), pp. 9-14; 39 (1937), pp. 9-15).—Notes on the occurrence of the more important pests and the results of experimental work are presented (E. S. R., 73, p. 206). That in No. 39 relates to control of the strawberry blossom weevil *Anthonomus rubi* and the black currant eelworm *Aphelenchoides ribes*, insect and allied pests of cultivated mushrooms, pyrethrum, weevils of the genus *Rhynchites*, control of the currant bud mite, and the value of *Aphelinus mali* as a parasite of the woolly apple aphid.

Additions to Hebard's list of Orthoptera of South Dakota, with observations on some previously recorded species, H. C. SEVERIN (*Jour. Kans. Ent. Soc.*, 9 (1936), No. 3, pp. 85-98).—This contribution records and notes 17 species of Orthoptera occurring in South Dakota additional to those reported by M. Hebard in 1925.²

Differences in the resistance of the instars of a pentatomid bug to pyrethrum powder, F. B. NOTLEY (*Bul. Ent. Res.*, 27 (1936), No. 4, pp. 607-609, fig. 1).—During the course of the testing of finely ground pyrethrum flowers as an insecticide for the control of *Antestia lineaticollis* Stål in coffee trees, the author observed that various instars showed different percentage death rates under the same conditions. The experiments which followed are briefly reported upon.

A new species of *Nysius* (Hem., Lygaeidae) from Tasmania, and notes on the economic importance of the genus, J. W. EVANS (*Bul. Ent. Res.*, 27 (1936), No. 4, pp. 673-676, fig. 1).—Following a description of the new species *N. turneri*, a brief summary is given of the importance of the genus *Nysius* and their life history, habits, and control.

The toxicity of certain insecticides to the chinch bug, C. H. RICHARDSON, C. C. DEONIE, and W. A. SIMANTON (*Jour. Agr. Res. [U. S.]*, 54 (1937), No. 1, pp. 59-78, figs. 6).—As a contribution from the Iowa Experiment Station, the results of a laboratory and a field investigation to determine the effectiveness of certain contact insecticides against the chinch bug are reported, the details being given in tables and graphs. In the laboratory five soaps (sodium oleate, sodium-base laundry soap, pure potassium oleate, commercial potassium oleate, and commercial potassium fish oil soap), two kerosene emulsions, nicotine, piperidine, pyrethrum extract, rotenone, and derris extracts were applied as sprays under standardized conditions to the various stages of the insect. In the field, three commercial soaps, several petroleum oil emulsions, nicotine sulfate, a preparation containing dipyridyls, pyrethrum extract, and rotenone and

² Acad. Nat. Sci. Phila. Proc., 77 (1925), pp. 33-155, figs. 3.

derris extracts were tested as sprays on chinch bugs in corn. Calcium cyanide, sodium fluoride, nicotine-bentonite mixture, anabasine-bentonite mixture, and powdered derris root were applied as dusts.

In the laboratory experiment laundry soap was the most toxic, no significant differences being found among the other soaps tested. The adult chinch bugs were generally more resistant than the younger forms. Kerosene emulsion at high oil concentrations was only mildly toxic; emulsions which contained naphthalene dissolved in the oil were more toxic. Nicotine was more toxic to the adults than to the younger stages. Piperidine was relatively nontoxic. Pyrethrum extract in dilute acetone solution was highly toxic on the basis of total pyrethrin content and about equal to derris extract when the concentration of the latter was expressed as rotenone. On the above-mentioned bases both pyrethrum extract and derris extract were much more toxic than rotenone, and the latter was almost nontoxic to adults and fifth-instar nymphs. There was no difference in toxicity between acetone and carbon tetrachloride extracts of derris.

In the application of sprays in the field laundry soap was no more effective than commercial potassium oleate or potassium fish oil soap. The former was less injurious to the plant, suggesting that soaps of the higher saturated fatty acids (palmitic and stearic) may be less toxic to the corn plant. The alkalinity of the soaps may also be a factor. Nicotine and pyrethrum extracts gave results in substantial accord with those of the laboratory. Rotenone was less effective in the field than in the laboratory, as were also the derris extracts. Dipyridyl oil was noninjurious to the plant at effective concentrations.

Of dusts applied in the field calcium cyanide was efficient only when the amounts were large enough to cause severe plant injury. The other materials used were valueless.

The approximate order of toxicity in the laboratory of the various materials tested based upon the median lethal concentrations for the adults was pyrethrins=derris extract (based on rotenone content)>nicotine>sodium-base laundry soap>other K and Na soaps>piperidine>kerosene-naphthalene emulsion>kerosene emulsion. Rotenone is not included because the toxicity data are insufficient.

A list of 45 references to the literature is included.

Land-improvement measures in relation to a possible control of the beet leafhopper and curly top. R. L. PIEMTSEL and J. C. CHAMBERLAIN (*U. S. Dept. Agr. Circ. 416 (1936), pp. 24, figs. 13*).—The data here presented, based upon reconnaissance surveys of weed hosts and leafhoppers throughout southern Idaho and on detailed studies of selected fields and plats, show that the application of certain land-improvement measures would result in a large measure of control of the beet leafhopper and the curly top disease that it transmits. This leafhopper is produced in economic numbers only on the weed host stands which grow on abandoned, weedy fallow, burned-over, or heavily grazed lands, and not in economically significant numbers on well-farmed lands and desert range in good condition.

"Under favorable conditions these weed hosts will ultimately be replaced by a combination of desert shrubs, perennial grasses, perennial herbs, and other plants that are not breeding hosts of the beet leafhopper. For the greater part of southern Idaho such complete re-establishment of native perennials is not necessary for the elimination of weed hosts, since downy chess, not a host, forms an intermediate stage. In favorable situations the replacement of weed hosts by downy chess takes place in about 5 yr. The portion of southern Idaho here considered is divided into three categories—the primary, secondary, and

potential areas. The primary areas are considered the most important leafhopper-breeding areas and are those needing the first efforts at rehabilitation. The beet leafhopper and curly top can be controlled provided that all lands not continuously farmed and well farmed can be restored to and maintained as good desert range. The measures proposed for the accomplishment of this are similar to those contemplated or now under way for purposes of land conservation and differ only in the results sought for, that is, the control of the leafhopper and curly top instead of increased forage or prevention of soil erosion. Unless present practices are corrected, an increase of the weedy areas, leafhopper populations, and curly top can be expected."

Spruce gall aphids in nursery and ornamental plantings, F. L. GAMBRELL (*Farm Res. [New York State Sta.]*, 3 (1937), No. 3, pp. 1, 5, figs. 3).—The spruce aphid, which attacks principally Norway and white spruces but may be found to some extent on other species of spruce, previously reported upon (E. S. R., 73, p. 74), and the Sitka aphid, which occurs largely on Colorado blue spruce, on which it causes very definite injury, and is also present on Douglas fir during part of its life history, are considered, particularly as relates to their control. The Sitka aphid, which is more commonly found on trees in the home planting, has recently proved to be a pest in some commercial nurseries as well. Its life history is somewhat similar to that of the spruce aphid but is much more complicated, having both primary and alternating hosts, namely, the Colorado or Sitka spruces and Douglas fir.

Experiments conducted for the past several years are said to have clearly demonstrated that these aphids can be effectively controlled by one thorough application of any one of several mixtures described. Their application should be made during the dormant season, with a view to killing the immature aphids that overwinter on the bark. Ordinarily treatment can be made any time between the middle of October and the latter part of April that weather conditions permit.

New California Aphididae, E. O. ESSIG (*Pan-Pacific Ent.*, 12 (1936), No. 2, pp. 65-72, figs. 4).—Three species of Aphididae, including *Myzus langei*, taken on the under sides of the leaves of water cress near Sonora, Calif., and to which the name water cress aphid is given, are described as new.

The problem of black scale (*Chrysomphalus ficus* Ashm.) in Palestine, C. SCHWEIG and A. GRUNBERG (*Bul. Ent. Res.*, 27 (1936), No. 4, pp. 677-714, pl. 1, figs. 9).—An extended account is given of studies of the biology and control of this scale in Palestine, detailed in tables and graphs.

Ecological observations upon the enemies of *Cecropia*, with particular reference to its hymenopterous parasites, F. L. MARSH (*Ecology*, 18 (1937), No. 1, pp. 106-112, figs. 2).—A study made of the feeding interrelationships existing between scattered clumps of black willow, boxelder, and wild cherry in an area near Summit, Ill., the *Cecropia* larvae with which they were heavily infested, and the involved chain of hymenopterous parasites and hyperparasites is reported upon.

Fruit-piercing Lepidoptera in Sierra Leone, E. HARGREAVES (*Bul. Ent. Res.*, 27 (1936), No. 4, pp. 589-605, figs. 6).—Observations of the fruit-piercing Lepidoptera in Sierra Leone, where grapefruit, sweet orange, mandarine, tangerine, and sweet lime are affected in addition to cashew, mango, breadfruit, and jackfruit, are reported upon.

A ten year study of codling moth activity, R. L. WEBSTER (*Washington Sta. Bul.* 340 (1936), pp. 40, figs. 22).—A comparison made of codling moth activity in the Pacific Northwest commenced in 1928, in which year traps were first employed to determine the proper time of application of cover sprays, indicates

a wide range of variation from year to year. The records, details of which are graphically presented in 22 charts, have shown worm damage in any orchard to depend largely on the initial infestation. "The greater the population of overwintering worms, other things being equal, the greater the damage. An increasing moth population has been accompanied by greater irregularity in moth emergence, especially between broods. Temperatures in May, influencing the extent of egg-laying and the development of first brood worms, are of great importance in determining codling moth activity during the season. Temperatures during both August and September determine the extent of second brood worm activity. Warm weather late in the season may counterbalance cool May temperatures, and vice versa. Low winter temperatures appear less important than spring and summer temperatures. Low temperatures during the winter months were important during only 1 yr. in the 10-yr. period, i. e., in 1930. In this case May temperatures were also unfavorable. There is some correlation between size of the apple crop and worm damage. In general, a light crop following a heavy one is subject to greater damage. Conversely, when a large crop follows one much smaller, less injury may be anticipated. Peaks of moth emergence occur at practically the same times in Yakima, Wenatchee, and Omak. Little correlation exists between moth records obtained at Prosser when compared to those obtained at Yakima and Wenatchee."

The oriental peach moth in the Goulburn Valley (Vic.) (*Jour. Council Sci. and Indus. Res. [Austral.], 9 (1936), No. 4, pp. 320, 321*).—Brief reference is made to the oriental fruit moth, an outbreak of which occurred in 1933-34 and caused serious losses to the canned peach industry of the Goulburn Valley of Victoria. In 1934-35, "the loss was [from] 20 to 28 percent, but in the 1935-36 season the loss was estimated at [from] 50 to 52 percent, which was almost as serious as the outbreak of 1933-34."

Although peaches are the chief fruits attacked by the moth, almond fruit and twigs, apricot fruit, plum twigs, pears, and quinces are also attacked. Reference is made to work with the fruit moth parasites *Macrocentrus ancylivorus* and *Glypta rufiscutellaris*, introduced from the United States in 1935.

A method of testing oils and other chemical agents for killing mosquito larvae, J. CACCHI, W. SELLERS, and J. D. BUNKALL (*Bul. Ent. Res., 27 (1936), No. 4, pp. 649-652*).—A description is given of a method devised by the authors.

Studies on the higher Diptera of medical and veterinary importance.—The warble flies of the genus *Hypoderma*, W. S. PATTON (*Ann. Trop. Med. and Parasitol., 30 (1936), No. 4, pp. 453-468, figs. 12*).—A continuation of this contribution (*E. S. R., 76, p. 77*), in which the diagnostic characters of the terminalia of both sexes of species, including the common cattle grub, *H. diana* Brauer, *H. tarandi* L., *H. crossi* Patton, and *H. aeratum* Austen, are described and illustrated.

New or little-known species of West Indian "Tipulidae" (Diptera) L. I., C. P. ALEXANDER (*Jour. Agr. Univ. Puerto Rico [Col. Sta.], 20 (1936), No. 4, pp. 877-882, figs. 4*).—Two new species of crane flies from Puerto Rico, one from Cuba, and one from the Bahamas are described.

The breeding media of some common flies, M. THOMSEN and O. HAMMER (*Bul. Ent. Res., 27 (1936), No. 4, pp. 559-587, figs. 4*).—Observations of the breeding habits of the stablefly and the housefly on a large number of farms in Denmark, together with oviposition experiments conducted in 1933 and notes on the reactions of other species during experiments, are reported upon in this further contribution (*E. S. R., 72, p. 664*). The contribution is presented with a list of 34 references to the literature.

A comparative study of the first-instar larvae of the genus *Sarcophaga* (Calliphoridae, Diptera), with notes on the biology, E. F. KNIPLING (*Jour. Parasitol.*, 22 (1936), No. 5, pp. 417-454, pls. 5).—Following an introductory account of the habits and life history, larval characters, and a general description, a comparative study of 24 species of *Sarcophaga* (Calliphoridae, Diptera) in the first larval instar is reported upon.

The growth stimulation of blow-fly larvae fed on fatigued frog muscle, H. G. P. SMITH (*Jour. Expt. Biol.*, 13 (1936), No. 3, pp. 249-252).—It has previously been shown that blowfly larvae (*Calliphora erythrocephala*) fed on fatigued frog muscle grew to a size larger than controls fed on resting muscle (E. S. R., 69, p. 694). The author has now demonstrated that the growth-stimulating substance is thermolabile and that it passes from the contracting muscle into the blood stream. It does not accumulate in the liver. The bacterial flora is equally dense on resting and on fatigued muscle on which fly larvae have fed.

The currant and gooseberry maggot or yellow currant fly (*Epochra canadensis* Loew), S. C. JONES (*Oregon Sta. Circ. 121* (1937), pp. 11, figs. 10).—This is a practical summary of information on the currant fruitfly, a serious pest of both currants and gooseberries in Oregon. Biological studies of this dipteran, with a chart illustrating its seasonal history on gooseberries in the Willamette Valley, and means of control are included.

The application of a poison bait spray consisting of arsenate of lead (2 oz.), cheap molasses (1 qt.), and water (3 gal.) is recommended as the most effective insecticidal treatment available. It is recommended that the first spray be applied within 1 week after the flies begin to emerge or when the gooseberries begin to set fruit, and followed at weekly intervals until a week before harvest, being repeated after every rain.

Coleoptera of an original prairie area in eastern Nebraska, D. B. WHELAN (*Jour. Kans. Ent. Soc.*, 9 (1936), No. 4, pp. 111-115).—An annotated list is given of the Coleoptera collected from the vegetation of a 320-acre tract of original low and upland prairie located about 9 miles northwest of Lincoln, Nebr.

Distributional notes on Utah Coleoptera, II, G. F. KNOWLTON (*Jour. Kans. Ent. Soc.*, 9 (1936), Nos. 3, pp. 107, 108; 4, pp. 109-111).—This is a further contribution on the distribution of Coleoptera in Utah (E. S. R., 72, p. 510), contributed from the Utah Experiment Station.

The Cicadellidae of Cuba, Z. P. METCALF and S. C. BRUNER (*Jour. Agr. Univ. Puerto Rico [Col. Sta.]*, 20 (1936), No. 4, pp. 915-973, pls. 6).—Keys are given to the genera and species of Cicadellidae, of which no less than 32 forms are recorded from Cuba. Five genera (*Hortensia*, *Hadria*, *Ciminius*, *Acrezia*, and *Lucumius*) are erected, and 21 species and 2 varieties are described as new.

A bibliography of 52 titles is included.

The furniture carpet beetle *Anthrenus vorax* Waterhouse, a pest of increasing importance in the United States, E. A. BACK and R. T. COTTON (*Ent. Soc. Wash. Proc.*, 38 (1936), No. 9, pp. 189-198, figs. 2).—In addition to the three species of carpet beetles that are of major economic importance throughout the United States, due to their destructiveness to house furnishings, namely, the carpet beetle, the varied carpet beetle, and the black carpet beetle, there is a fourth species, the furniture carpet beetle *A. vorax*, which is practically unknown except in Washington, D. C. This Old World species, first collected in Augusta, Ga., in 1911, was observed at Washington, D. C., in 1915, where it has become thoroughly established and is today the most destructive of all the carpet beetle and fabric pests and the cause of considerable loss

to property owners. It has also made its appearance at isolated points in other eastern States, extending from New York to Florida.

A study of its life history has shown the female to lay from 37 to 96 eggs, sometimes as many as 57 eggs in one batch. "During warm summer weather at Washington eggs hatch in 10 to 15 days, and the complete life cycle or generation requires about 1 yr., with some individuals requiring 2 yr. The pupal stage lasts from 9 to 13 days in summer, and adults may live several months, although, if laying eggs, they usually die within 2 weeks. By far the greatest period of the insect's life is spent in the feeding or larval stage.

"This beetle is exceedingly destructive when it finds access to stored commodities. It is very fond of hair-filled furniture, brushes, and carpeting, but feeds on all kinds of animal substances. It does not normally feed on substances of vegetable origin, but sometimes injures cotton, linen, rayon, and jute fabrics and silk, and in fact almost anything edible that has become stained or polluted with animal excretions."

A list is given of 16 references to the literature.

The fir engraver beetle, a serious enemy of white fir and red fir, G. R. SEURLE (*U. S. Dept. Agr. Circ. 419* (1937), pp. 16, pls. 4, figs. 3).—This contribution reports upon the hosts and distribution of *Scolytus ventralis* Lec., a major cause of widespread damage and destruction to forests of fir in the West, its life history and habits, seasonal generations, character of damage, host susceptibility and resistance, associated insects of secondary importance, insect enemies, and artificial control measures.

"From 1928 to 1930, and again in 1932, sporadic outbreaks of local nature appeared in California and Oregon, doing considerable damage to second-growth forests. White fir, lowland white fir, and California red fir are the preferred host trees, but occasional damage is done to Douglas fir, mountain hemlock, alpine fir, and Engelmann spruce. The range of *S. ventralis* is known to extend from British Columbia to New Mexico and east to the Rocky Mountains.

"The beetle kills or damages its host by cutting transverse egg galleries along the cambium layer, resulting in girdling of the trunk or in patches of dead cambium. The larvae mine separate channels at right angles to the egg gallery along the cambium layer, causing further damage. A fungus stain introduced by the beetle and found with every attack is apparently an important factor in insuring the success of the beetle, as it apparently assists in overcoming the resistance of the host.

"The length of the life cycle depends on prevailing temperatures at the altitude and latitude of the host trees. In the central Sierra Nevada one generation is produced each year at elevations between 4,500 and 6,000 ft., one generation every 2 yr. at elevations above 6,000 ft. on north exposures, and one and a partial second generation at elevations between 3,500 and 4,500 ft. on south exposures. The broods hibernate only in the larval stage. The egg stage and the pupal stage are completed within 10 to 14 days. Adults are in flight from June into September, the maximum number being found during July and August. Under normal conditions *S. ventralis* breeds in old or weakened trees, killing the tops or patches of cambium along the bole. . . .

"Trees weakened by the fir engraver beetle are often readily attacked and killed by several species of associated secondary insects. The cerambycid *Tetropium abietis* is the most important in this group. *S. ventralis* is held in check naturally by several species of parasitic and predaceous insect enemies whose numbers increase with the numerical increase of the beetle. Artificial control measures are limited because of the wide variation in kill and brood establish-

ment. Unless the broods in top-killed trees or in partially injured boles can also be destroyed, the benefit from destroying broods in trees killed is largely nullified. The most practical means of control is by felling, peeling the bark, and burning."

Prothetely in larvae of the confused flour beetle (*Tribolium confusum* Jacq. Duv.), M. J. OOSTHUIZEN and H. H. SHEPARD (*Ann. Ent. Soc. Amer.*, 29 (1936), No. 2, pp. 268-272, fig. 1).—A contribution from the Minnesota Experiment Station, presented with a list of 13 references to the literature.

The biology of *Ips perturbatus* Eichhoff, A. R. GUBIEL (*Canad. Jour. Res.*, 1: (1936), No. 12, Sect. D, pp. 181-204, pl. 1, figs. 4).—Studies made of the biology of the bark beetle *I. perturbatus* in the Gaspé Peninsula during the summers of 1933 and 1934 are reported upon, details being given in seven tables. This species, which generally breeds on trees killed by *Dendroctonus piceaperda* Hopk., was also found on white spruce dying from attacks of the European spruce sawfly (*Diprion polytomum* Hartig). There was found to be one complete generation a year in the Gaspé Peninsula, young adults leaving their host tree at the end of September and the beginning of October to hibernate in the ground, from which they emerge in the spring.

"Experiments show that the adult stage lasts nearly 2 yr. During their first complete summer as adults the females lay two sets of eggs. The following spring they lay a third set and die during the summer. There are [from] one to four egg tunnels per engraving. The average number of eggs per egg tunnel decreases with the increase in the number of females per engraving. Dissection of 500 beetles indicates that the two sexes are present in about equal proportions. Analysis of the results of a population study made on a white spruce representing 48 ft. of tree superficies attacked by *I. perturbatus* produced the following results: 2,418 egg tunnels, 22,512 young beetles, 58,800 egg niches, and a mortality rate of 58.33 percent. *Coeloides dendroctoni* Cushman is the most important parasite of this species, but does not kill more than 5 percent of the larvae and pupae. No trace of woodpecker control was noticed."

The life history of "*Diaprepes abbreviatus*" L., at Rio Piedras, Puerto Rico, G. N. WOLCOTT (*Jour. Agr. Univ. Puerto Rico [Col. Sta.]*, 20 (1936), No. 4, pp. 883-914, figs. 7).—Studies of the life history of the otiorhynchid beetle *D. abbreviatus* (the adults of which are known as "vaquitas"), conducted by the Puerto Rico College Experiment Station, are reported. Nurseries and young newly set citrus trees are much more often attacked (or at least the feeding of the adults is more obvious) than are the older trees. They feed almost exclusively on young tender foliage, but when exceptionally abundant they may attack also the older leaves. The beetles also feed on the leaves of many other kinds of trees, and in the case of *Andira inermis* at times cause complete defoliation. The roots are fed upon by the grubs.

The females lay about 5,000 eggs in as few as 2 mos., May and June, or in as many as 7 mo. at other times of the year, often living over twice as long as do the males after emergence from the soil. "The incubation period of all eggs is 7 days. Larvae attain full size in 2 to 4 mo. A diapause period is absolutely essential before pupation. The pupal period is about 2 weeks. Fully-formed adults remain within the pupal chamber for a variable period of weeks or months, the length of this period and that of the diapause period of the larva being subject to great variation. The great variation in the duration of the diapause period of the larva and before the emergence of the adult from the pupal cell in the ground permits some individuals to complete their

life cycle (hatching of eggs to first egg cluster laid by female, or to emergence of male from soil) in less than 8 mo., but for other individuals it may extend for 18 mo. (hatching of egg to last egg cluster laid by female, or to death of male).

"Deviation from a 1-yr. life cycle is of tremendous value to *D. abbreviatus* L. in enabling its eggs to escape attack by a common parasitic wasp, *Tetrastichus haitiensis* Gahan, which is most abundant during the late spring, but very scarce during autumn and winter."

A list is given of 21 references to the literature.

Host relationships of the larger apple curculio, *Tachypterellus quadrigibbus magnus* List, P. O. RITCHER (*Jour. Kans. Ent. Soc.*, 9 (1936), No. 3, pp. 94-99).—This contribution from the Wisconsin Experiment Station deals with variations within the subspecies *T. quadrigibbus magnus* as it occurs on wild and cultivated hosts growing in the Kickapoo Valley apple district of Wisconsin. The fact that this curculio varies greatly in size is said to be due in large part to the fact that *Crataegus* produces small curculios and the cultivated apple large curculios. That there is much less transfer between the two hosts than might be expected is thought to result from the feeding and egg laying preferences and the sluggishness of the curculios.

The practical use of the sun in cowpea weevil control, R. R. REPEET and M. R. BENTLEY (*Jour. Kans. Ent. Soc.*, 9 (1936), No. 4, pp. 126-139).—The experiments reported, the details of which are given in tables, have shown that exposure of cowpeas to open sunlight on a clear day with no wind blowing between the hours of 10 a. m. and 4 p. m. when shade temperatures are 98° F. or more, for a period of 75 min. or more, will result in the complete destruction of all stages of weevils that may be infesting them. A similar exposure continued for as long as 5 hr. is not seriously injurious to germination, provided the shade temperature is not greater than 100°. Exposure under the same conditions but covered with glass, for a period of 15 min., will result in the complete destruction of all stages of weevils that may be infesting them. When continued for as long as 1 hr. there is no serious injury to germination, provided the shade temperature is not greater than 96°. When continued for as long as 5 hr. the percentage of germination is considerably reduced but the vigor of the resulting plants is not impaired.

The Mexican cotton boll weevil, *Anthonomus grandis* Boheman, in Haiti, A. AUDANT and A. OCCÉNAD (*Jour. Agr. Univ. Puerto Rico [Col. Sta.]*, 21 (1937), No. 1, pp. 69-76, figs. 5).—The bollweevil, supposed to have been introduced by accident into Haiti, probably in the personal effects of returned emigrants from Cuba or in commerce by boats from Texas, about 1932, first came to the attention of cotton growers close to Jacmel through the number of fallen squares noted in the crop of 1932-33, although the loss was not sufficiently severe to cause alarm at that time. During the following season the infestation spread to other regions, but it was so light as to attract little attention from the growers. By the end of January 1935 the crop was a complete loss in the Jacmel region, and by June 1935 the pest had become established to the north and east of Port-au-Prince and before the end of the harvest had reached the neighborhood of l'Arcahaie and the lower slopes of Morne à Cabrits. Up to the end of 1936 the regions of St. Marc and of the Plateau Central had remained free from the pest, under the protection of a very severe quarantine.

The extent of the losses caused the cotton crop in Haiti is considered at some length.

The ants of Puerto Rico, M. R. SMITH (*Jour. Agr. Univ. Puerto Rico [Col. Sta.]*, 20 (1936), No. 4, pp. 819-875, figs. 19).—Keys are given for the separation of the subfamilies and species of worker ants, together with notes on the characters, occurrence, food habits, etc., of 66 ant forms recognized as occurring in Puerto Rico. One species and one subspecies are described as new to science. The contribution is based upon work in Puerto Rico from July 1935 to June 1936. A review of the literature with a list of 17 references is included.

Descriptions and records of California Mutillidae, C. E. MICKEL (*Pan-Pacific Ent.*, 12 (1936), No. 2, pp. 91-96).—Descriptions of three new mutillid species are included in this contribution from the Minnesota Experiment Station.

Laboratory breeding of *Ascogaster carpocapsae* Vier., with notes on biology and larval morphology, H. R. BOYCE (*Canad. Ent.*, 68 (1936), No. 11, pp. 241-246, figs. 9).—As noted from a study made at the Dominion Parasite Laboratory at Belleville, Ontario, 9,349 adults of *A. carpocapsae* which were reared in the laboratory have been released in several areas in British Columbia to control the codling moth. It is pointed out that this species is widely distributed in Europe and eastern North America, where it parasitizes a number of lepidopterous forms. A short account is given of its biology, with a description of its several stages, chiefly as a comparison with studies made by earlier workers. The breeding technic is described in full, and a detailed account given of shipping methods and liberation areas. Recoveries are said to have been made from liberations in 1935 in an unsprayed orchard near Victoria.

ANIMAL PRODUCTION

Animal breeding plans, J. L. LUSH (Ames, Iowa: Collegiate Press, Inc., 1937, pp. VIII+350, figs. 41).—This book is intended primarily as a text for college students in advanced animal breeding courses and deals with the means available for improving the heredity of farm animals, particularly stressing the possibilities and limitations of each method. The different sections deal with the background of animal breeding, genetic principles, breeding plans based on selection, on relationship, and on somatic likeness, other topics concerning breeding plans, reproduction, and general considerations.

[Livestock investigations in Delaware] (*Delaware Sta. Bul.* 205 (1936), pp. 19-23).—Data are reported continuing earlier work (E. S. R., 76, p. 668), including that on dried distillers' and dried brewers' grains for growing fattening pigs and forage crops for pigs, both by A. E. Tomhave, and the necessity of breeding for desirable factors in high egg production and viability, protein levels of rations in growing chicks, and germinated oats for laying pullets, all by Tomhave and C. W. Mumford.

[Livestock investigations in Iowa] (*Iowa Sta. Rpt.* 1936, pts. 1, pp. 72, 73, 75, 76, 81, 82, 83-85, 88-92, 93, 94, 95, 96, fig. 1; 2, pp. 58, 59).—Swine studies reported include the consequences of inbreeding Poland China hogs, by J. L. Lush and C. C. Culbertson: the value of the Danish Landrace breed in the development of improved strains of swine for American conditions, and the evaluation of swine breeding stock, both by Lush, Culbertson, M. D. Helser, F. J. Beard, B. H. Thomas, and J. A. Schultz; spring v. fall pigs, by Culbertson, A. L. Anderson, Helser, Beard, and Thomas; the relative efficiency of different sources of calcium for growing and fattening pigs, by Culbertson and Thomas; the relative efficiency of different types of corn for growing and

fattening pigs, by Culbertson, Anderson, and J. L. Robinson; and the influence of different amounts of soybeans and oil in the ration of swine upon the character and quality of body fat and lard, and upon the keeping quality of the lard, by Culbertson, Beard, Helser, Thomas, and J. H. Buchanan.

Other livestock studies yielded information on the preparation of roughages for draft colts, and factors involved in the production of colts, both by A. B. Caine; rations for finishing steer calves in dry lot, and the influence of sex and also the influence of menhaden oil and coconut oil on the quality and palatability of beef, both by Helser, Beard, Culbertson, and Thomas, with P. M. Nelson cooperating on the meats studies.

Poultry investigations gave results on the effect of diet on the quantity of vitamins A and D occurring in hens' eggs, by Thomas; the biological value of meat scrap and milk combinations for egg production, and the value of egg yolk and chicken fat as preventives of rickets and slipped tendons of chicks, both by E. W. Henderson; a comparison of avian growth rates, by Henderson and T. T. Milby; and the effect of various levels and sources of protein and inorganic elements in the ration upon slipped tendons in chicks and poults, caponizing turkeys, and artificial lights for turkeys, all by H. L. Wilcke, Henderson, C. Murray, and C. D. Lee.

[Livestock experiments in New Mexico] (*New Mexico Sta. Rpt. 1936, pp. 34-36, 66-69*).—Progress is reported on the investigations previously noted (E. S. R., 75, p. 87), including additional data on the importance of alfalfa hay in different proportions in replacing hegari fodder for fattening lambs and on the phosphorus and calcium content of the important livestock grazing forages in different sections of the State, and the influence of different range crops and rations on egg quality, production, and mortality.

The technical conditions of preparation and the biological value of fish meals [trans. title], N. J. CHLEBNIKOW and A. F. ARSINJEV (*Biedermanns Zentbl., Abt. B, Tierernähr., 8 (1936), No. 6, pp. 565-579; Eng. abs., p. 578*).—The effect of certain treatments in the process of preparing various fish meals on the biological value of the protein has been studied in trials with growing chicks. The use of fish meal containing up to 9.47 percent of salt and 7.15 percent of fat in the chick ration caused no disturbance in growth. The process of soaking decreased the vitamin B₁ potency of the meal but did not affect its protein value. On the basis of growth-promoting quality and biological value of the proteins, the meals were ranked as follows: (1) Herring meal, soaked and extracted; (2) herring meal, not soaked and not extracted; (3) herring meal, from fresh fish, extracted; and (4) herring meal, soaked, but not extracted. The three codfish meals tested all ranked below the herring meals.

The yield of crude and digestible nutrients from clover and meadow grass under different methods of conservation [trans. title], K. BASELER (*Biedermanns Zentbl., Abt. B, Tierernähr., 8 (1936), No. 6, pp. 509-544; Eng. abs., pp. 543, 544*).—In a series of digestion trials with wethers over a 2-yr. period, clover and meadow grass hay dried on various types of scaffolds or riders was practically equal in digestibility to silage (cold fermentation process) from the same source, providing the hay was free from mold and otherwise of good quality. Ensiling proved by far the most effective means of conserving the starch value and protein content present in the green feed, while of the drying methods the thin wire rider ranked first, followed by the trestle rider, the Allgäu cottage, and drying on the ground. Feeding trials with cows comparing the nutritive value of the silage and hay dried on trestle riders confirmed the results of the digestion trials.

Investigations on silage and A. I. V. fodder conservation [trans. title], H. ISAACHSEN, O. ULVESLI, and M. HUSBY (*Meld. Norges Landbr., Høiskole., 16* (1936), No. 3-5, pp. 309-360; *Eng. abs., pp. 353, 359*).—This report summarizes several years' trials in preparing silage from grass and aftermath, comparing the keeping quality and composition of ordinary silage with those receiving additions of either mineral salt solutions (NaCl , Na_2HPO_4 , and CaCl_2), sour whey, or hydrochloric acid (A. I. V. process). Results of trials with ordinary potato silage and A. I. V. potato silage are also noted. A complete tabulation of the composition of all lots and the percentage recovery of nutrients in the various lots of silage is presented.

In general, the nutritive values of the conserved fodders are high, ranging from 59 to 92 feed units per 100 kg of dry matter in the silage. Some ammonia was found in all silage samples, with the least amounts occurring in the A. I. V. lots. Organic acid contents varied widely, lactic acid ranging from 0.12 to 2.9 percent, and butyric acid, which was found in practically all samples, ranging from 0 to 1.2 percent.

Effect of method and rate of grazing on beef production and plant population of pastures at Beltsville, Md., M. A. HURN and A. C. COOK (*U. S. Dept. Agr., Tech. Bul. 538* (1937), pp. 35, figs. 16).—Three similar permanent pasture areas seeded with a complex mixture in 1928 were grazed with beef steers for 6 seasons (1929-34) under different methods and rates of grazing. Pasture 1 was grazed continuously at the rate of one animal unit to two acres, pasture 2 was grazed continuously at the rate of one animal unit per acre, and pasture 3 stocked at the rate of one animal unit per acre was divided into two equal parts which were grazed alternately.

The plant population was affected by the rate and method of grazing, Canada bluegrass, timothy, orchard grass, and lespedeza predominating under light continuous grazing, while Kentucky bluegrass and white Dutch clover predominated under heavy continuous grazing. The harvested growth from protected areas indicated that over one-half of the total herbage was produced during the first one-third of the grazing season. Analysis of three samples showed a calcium:phosphorus ratio of approximately 2:1 and an average protein content for the season of 13.67 percent. The 6-yr. average gains per steer on pastures 1, 2, and 3 were 287, 196, and 194 lb., respectively, and the average gains per acre for the 6-yr. period were 145, 196, and 194 lb., respectively. Steers on the lightly grazed areas which gained 92 lb. more than those on the heavily stocked areas were considerably better finished at the close of the season. Surplus forage remaining on the ground of the lightly grazed area at the close of the regular season in 1933 and 1934 produced an additional gain of 43 lb. per acre when grazed by thin feeder cattle in late fall and early winter.

The role of the connective tissue in the pH determination of meat [trans. title], H. KELLER (*Ztschr. Fleisch. u. Milchw. 47* (1936), No. 5, pp. 89, 90).—Connective tissue of freshly slaughtered animals has an extraordinarily high pH value, generally ranging from pH 7 to 7.4. On this basis muscle high in connective tissue should not be employed for pH studies, since the values obtained will be greater than actually exist in muscle low in connective tissue. Muscle tissue found satisfactory for such studies includes the rectus abdominis, gracilis, and pectoralis muscles. Excessive connective tissue tends to increase the pH value of the surrounding blood and fat, and on this basis sausage high in connective tissue is relatively unstable. The fact that putrefaction is first observed in the connective tissue elements of the carcass is attributed to their high pH value.

Sheep, L. J. HORLACHER and C. HAMMONDS (*Lexington, Ky.: Commercial Ptg. Co., [1936], pp. XII+305, figs. 150*).—This book presents approved methods in sheep production and management, and while primarily intended for the student in vocational agriculture it should serve as a convenient manual for those already engaged in sheep production. Successive chapters discuss: Planning for the sheep enterprise, choosing the breed, selecting and judging, feeding and managing the flock from breeding to lambing, feeding and caring for the ewes and lambs, fattening commercial lambs, preventing and controlling common parasites and diseases in sheep and lambs, producing and handling wool, marketing lambs and sheep, and fitting and showing sheep.

The golden hoof: A practical sheep book [edited by P. V. EWING] (*Chicago: Sheep Breeder, Inc., [1936], pp. 256, figs. 47*).—This volume is presented as a source of practical sheep information and represents contributions of 25 contemporary sheepmen, each a specialist in the subject treated.

Maintenance metabolism of growing swine [trans. title], K. BREIREM (*Biedermanns Zentbl., Abt. B, Tierernähr., 8 (1936), No. 5, pp. 463-498, figs. 2; Eng. abs., p. 496*).—Based on a series of fasting experiments with swine in an attempt to obtain a reliable function for the calculation of the maintenance requirement, the following equations were found to express the relationship between maintenance metabolism and body weight:

$$E = 154.74W^{0.809} \text{ or } E = 2131 \left(\frac{W}{100} \right)^{0.809}$$

or in case a proper fraction is preferred

$$E = 164.27W^{4/5} \text{ or } E = 2126 \left(\frac{W}{100} \right)^{4/5},$$

in which E is the maintenance metabolism for 24 hr., expressed as net energy requirement for maintenance, and W is the body weight. These results serve to confirm previous findings by the author (*E. S. R., 76, p. 86*). Of particular significance from the standpoint of experimental methods is the fact that a preliminary fast of from 8 to 10 days was required to arrive at true maintenance metabolism in 40- to 50-kg pigs.

Comparative studies of fattening in different types of pigs and with different rations [trans. title], C. KRONACHER, J. KLFESCH, and R. HUNDS-DÖRFER (*Ztschr. Zücht., Reihe B, Tierzücht. u. Züchtungsbiol., 35 (1936), No. 2, pp. 191-212*).—This report is a summary of a large number of experiments in which both cross-bred and purebred pigs were fattened under three different systems of feeding. Under the first system pigs received potatoes ad libitum plus a daily allowance of 1 kg of medium protein meal per head throughout the fattening period. Under the second system the pigs were fed green alfalfa and a limited allowance of concentrate up to 70 kg live weight, after which they were fed according to the first plan. In the third system the pigs received potatoes ad libitum and a daily allowance of 2.5 kg of silage or other green feed and 0.5 kg of protein-rich concentrate. The latter system proved most economical, requiring less feed per unit of gain although requiring a slightly longer feeding period, while the second system proved the least desirable of the three. No significant differences were noted between the response of the cross-bred and purebred groups.

[Feeding trials with wood sugar yeast in the ration of swine] (*Biedermanns Zentbl., Abt. B, Tierernähr., 8 (1936), No. 6, pp. 594-607; Eng. abs., pp. 596, 599, 607*).—In fattening trials with pigs, reported from Tschechnitz by K. Richter and H. Brüggemann and from Kiel by H. Bünger, J. Schultz, and H. Augustin (with a general summary by Bünger) and in which the check ration contained beets, potatoes, and fish meal, substituting wood sugar yeast

(xylose yeast) for one-half the fish meal did not adversely affect appetites, rates of gain in weight, or feed utilization, but substitution of the yeast for all the fish meal resulted in failure. The yeast contained from 41 to 43 percent of digestible protein and had a starch value of 67 kg.

Temperature measurements on the working horse [trans. title], H. TOEPSCH (*Biedermanns Zentbl., Abt. B, Tierernähr.*, 8 (1936), No. 6, pp. 608-612; *Eng. abs.*, p. 612).—Temperature determinations made on the skin surface at different points on the bodies of horses showed a range of as much as 16° C. at diverse points, with highest temperatures occurring on the neck and the lowest on the back. Air temperature and rate of work greatly affected external body temperature, while the relative humidity of the atmosphere had little effect. Under like conditions, temperature measurements on the same part of the bodies of different horses showed little variation.

On the digestion of the cell wall constituents of feeds (lignin, pentosans, cellulose, and crude fiber) by the domestic hen [trans. title], A. TSCHERNIAK (*Biedermanns Zentbl., Abt. B, Tierernähr.*, 8 (1936), No. 5, pp. 408-462, fig. 1; *Eng. abs.*, p. 451).—Results of digestion trials with hens indicate that the cellulose, lignin, and pentosans of alfalfa meal are practically indigestible. In ground grains (wheat, corn, barley, or oats) and in ground soybeans the cellulose is likewise nearly indigestible, but lignins and pentosans are evidently digestible up to from one-eighth to two-fifths of their total content.

Comparative digestibility of ground and whole grain [trans. title], I. T. MASLIEFF and I. P. DENISSOFF (*Biedermanns Zentbl., Abt. B, Tierernähr.*, 8 (1936), No. 6, pp. 613-620; *Eng. abs.*, p. 620).—Results obtained in a series of trials with fowls indicate that in general grinding grain did not materially increase its digestibility. The digestibility of the fat in the ground grain averaged about 4.5 percent higher than in whole grain, but this is considered insignificant. A ground mash ration was digested more rapidly than whole grains as determined by rate of passage through the digestive tract, consequently mash feeding would permit a relatively larger feed consumption within a given time.

The feeding of pelleted feed [trans. title], R. FANGAUF and A. HAENFEL (*Arch. Geflügelk.*, 10 (1936), No. 10, pp. 353-358; *Eng. abs.*, p. 358).—Hens fed grain and pellets showed a decided preference for the grain. The time required for hens to become accustomed to pellets depended on the extent to which other feed was limited and also on the shape of the pellets, since it is shown that hens distinguish between different shaped pellets or nuts. The feeding of pellets had no advantage in any respect over grain feeding and was considered a complete failure from an economic standpoint.

Soybean oil meal prepared at different temperatures as a feed for poultry, J. W. HAYWARD, J. G. HALPIN, C. E. HOLMES, G. BOHSTEDT, and E. B. HAET (*Poultry Sci.*, 16 (1937), No. 1, pp. 3-14).—In a series of chick feeding trials at the Wisconsin Experiment Station, the use of high temperature expeller soybean oil meal (from 140° to 150° C. for 2½ min.), medium or high temperature hydraulic soybean oil meal (from 105° to 121° for 90 min.), or solvent extracted soybean oil meal (98° for 15 min.) as the primary source of protein in the chick ration resulted in chicks weighing almost twice as much at 8 weeks of age as those receiving the ground raw soybeans or low temperature expeller soybean oil meal (105° for 2 min.), while low temperature hydraulic meal (82° for 90 min.) gave intermediate results.

In trials involving various combinations of high temperature expeller meal, meat scrap, and dried milk in the ration of growing chicks and laying pullets,

rations containing 16 parts of soybean oil meal as the only protein concentrate proved inadequate, but a combination of 12 parts of soybean oil meal, 2 parts of meat scrap, and 2 parts of dried milk almost equaled an 8:4:4 or an all-animal protein 0:8:8 mixture with reference to growth of pullets at 20 weeks of age, and egg production of pullets over an 11-mo. laying period.

A study of the biological value of fish meals as determined by the raw material [trans. title], A. F. ARSENJEV and N. J. CHLEBNIKOW (*Biedermanns Zentbl., Abt. B, Tierernähr.*, 8 (1936), No. 6, pp. 580-593; *Eng. abs.*, pp. 592, 593).—It is shown that each of seven fish meals tested ranked higher than either casein or meat meal in growth-promoting value for chicks. All of the fish meals had a uniformly high coefficient of digestibility, ranging around 80 percent, and were adjudged as practically equal with regard to the biological value of the protein. However, they showed marked variation in vitamin B₆ content, certain ones failing to meet the requirements of growing chicks. Meals from the various sources are ranked on the basis of their growth-promoting value. The use of fish meal as the only source of animal protein in the chick ration is recommended. Fibrin, which has a very low biological value, may be combined with fish meal to give a product equal to casein in nutritive value.

A study of the effect of charcoal on chickens, also on the digestive function and feed utilization of fowls [trans. title], E. MANGOLD and H. DAMKÜHLER (*Arch. Geflügelk.*, 10 (1936), No. 8-9, pp. 289-316, fig. 1; *Eng. abs.*, p. 315).—The feeding of from 5 to 10 g of charcoal per hen daily checked or prevented diarrhea caused by feeding cane sugar in the mash or boiled potatoes as a sole diet. The voluntary intake of charcoal averaged 1.8 g per hen daily, or about 1.5 percent of the total ration. The addition of from 5 to 20 percent of charcoal in the ration of chicks or mature hens had no other noticeable effect, but in fattening cockerels its presence greatly accelerated the rate of growth. The presence of charcoal did not affect the digestibility of protein but slightly increased that of carbohydrates, particularly crude fiber.

The effect of feeding grit on digestibility in the domestic fowl, J. C. FRITZ (*Poultry Sci.*, 16 (1937), No. 1, pp. 75-79).—In studies by the U. S. D. A. Bureau of Animal Industry, two mature male birds were surgically altered to permit separate collection of urine and feces. These birds, which were reared on screen floors and without access to grit, were employed in a series of digestion trials to determine the effect of feeding grit on the digestibility of an all-mash ration and of southern field peas, each ration being tested with no grit, with from 3 to 6 g daily of fine granite grit, and with from 3 to 6 g daily of coarse granite grit. There was only a slight improvement in the digestibility of all constituents when grit was fed, and no significant differences were apparent from feeding the two sizes. The peas were shown to have a sufficiently high digestibility to justify their use in a poultry ration.

The vitamin A requirements of chicks with observations on the comparative efficiency of carotene and vitamin A, P. B. RECORD, R. M. BETHKE, and O. H. M. WILDER (*Poultry Sci.*, 16 (1937), No. 1, pp. 25-33).—In a series of feeding trials at the Ohio Experiment Station both prophylactic and curative types of feeding were employed to establish the minimum vitamin A requirements of growing chicks. Cod-liver oil, crystalline carotene, and alfalfa meal were used as sources of vitamin A, with the oil content of all rations kept constant by suitable additions of cottonseed oil. In the prophylactic trials the minimum requirement to promote normal growth and prevent symptoms of vitamin A deficiency to 8 weeks of age was established at from 50 to 100 μ g (micrograms) of carotene, or from 80 to 160 international units of Vitamin A

per 100 g of ration. In the curative trials it appeared that about 100 μ g of carotene, or from 120 to 200 units of vitamin A every other day, were required to cure and prevent symptoms of vitamin A deficiency in depleted chicks to 10 or 12 weeks of age. Carotene was effectively utilized by the chicks as a source of vitamin A, the response being similar to that obtained when equivalent rat units of the vitamin were supplied. The vitamin A requirement increased with age, and it is suggested that the minimum requirements as determined in this experiment may not be the optimum level under practical feeding conditions.

The vitamin A requirements of White Leghorn pullets during the growing period, G. E. BEARSE and M. W. MILLER (*Poultry Sci.*, 16 (1937), No. 1, pp. 34-38).—Chick feeding trials at the Western Washington Experiment Station in which varying levels of dehydrated alfalfa meal were fed as a source of vitamin A to 24 weeks of age showed that 175 Sherman-Munsell units of vitamin A per 100 g of ration met the requirements of growing White Leghorn pullets.

The effect of varying levels of vitamin A in the hen ration on the vitamin A content of the egg yolk, on hatchability, and on chick livability, G. E. BEARSE and M. W. MILLER (*Poultry Sci.*, 16 (1937), No. 1, pp. 39-43, fig. 1).—In these trials all groups of pullets reared on rations as described above were continued through their first laying period on rations containing the same levels of dehydrated alfalfa as employed during the growth period.

The vitamin A content in their egg yolk varied in proportion to the amount of vitamin A supplied in the ration, and the chicks hatched from the eggs lived and grew on vitamin A-deficient rations in proportion to the amount of vitamin A in the ration of the parent stock. Maximum hatchability was attained when 500 Sherman-Munsell units of vitamin A per 100 g of ration were fed.

The effects of storage on the vitamin D value of Columbia River salmon fish meal, J. S. CARVER, V. HERMAN, and J. L. ST. JOHN (*Poultry Sci.* 16 (1937), No. 1, pp. 68-74, fig. 1).—In chick feeding trials at the Washington Experiment Station salmon fish meal (17.4 percent fat) fed at either 2.9-percent or 5.7-percent levels in the all-mash ration gave complete protection against rickets. The same mixed ration after one year's storage still afforded protection at the same levels of feeding, but when the fish meal was stored separately for 1 yr. and then incorporated in the mix it gave protection at the 5.7-percent level but failed at the 2.9 level. It is suggested that the basal ration may have acted as an antioxidant in preventing loss of vitamin D in the salmon meal during storage.

Differentiation between vitamin G and an insoluble factor preventing a pellagra-like syndrome in chicks, A. T. RINGROSE and L. C. NORRIS (*Jour. Nutr.*, 12 (1936), No. 6, pp. 535-552, pl. 1, fig. 1).—This is a continuation of previous investigations (E. S. R., 66, p. 862), in which it has been found that egg white is greatly deficient in a pellagra-preventing factor but contains a fairly large amount of a growth-promoting factor for chicks, whereas purified casein is nearly adequate in a pellagra-preventing factor but very deficient in a growth-promoting factor.

In this experiment rations containing either commercial dried egg white or purified casein were fed to groups of chicks unsupplemented and supplemented with either dried liver, a water-alcohol liver extract, the extracted liver residue, heated dried liver, or liver autoclaved at pH 11. The results of these trials indicate that dried pork liver contains a factor necessary to prevent the pellagra-like syndrome in chicks on the egg white diet and also a factor necessary to promote growth on the purified casein diet. The antipellagra factor was insoluble in alcohol-water mixture and was destroyed by heating in a dry atmos-

phere and by autoclaving at pH 11, although not at pH 9. On the other hand, the growth-promoting factor was soluble in alcohol-water mixture, was stable to heating in dry atmosphere, and relatively stable to autoclaving at pH 11. This factor is designated as vitamin G. The evidence indicates that the syndrome developing on the egg white diet is identical with that developing to a lesser degree on the purified casein diet. Autoclaving dried egg white for 6 hr. at 15 lb. pressure at the natural pH (5.9 to 6) or at pH 9 overcame the tendency to produce this syndrome, probably due to the formation or release of the preventing factor during autoclaving.

Differentiation between vitamin G and a soluble factor preventing a pellagra-like syndrome in chicks. A. T. RINGROSE and L. C. NORRIS (*Jour. Nutr.*, 12 (1936), No. 6, pp. 553-569).—In further investigations it is shown that heating the purified casein diet (above) at from 95° to 100° C. for 144 hr. destroyed the pellagra-preventing potency of the ration. Supplementing this heated ration with dried pork liver prevented the pellagra-like syndrome and also promoted growth in chicks. It is shown that both the pellagra-preventing and growth-promoting factors present in the liver are soluble in alcohol-water mixture and are sensitive to, but are not destroyed by, autoclaving at pH 11. The pellagra-preventing factor was destroyed by heating in a dry atmosphere and was not adsorbed from the liver extract on fuller's earth, whereas the growth-promoting factor was relatively stable to dry heat and was adsorbed on fuller's earth. Thus vitamin G as defined above is a complex, containing both of these soluble factors. Further evidence indicates the identity of the pellagra-like syndrome which develops on the heated casein diet and on a raw egg white diet, and apparently both the alcohol-water soluble factor and the alcohol-water insoluble factor are required to prevent its development.

The "per cent firsts" as a measurement of egg size in pullet yields. W. C. THOMPSON (*New Jersey Stas. Bul.* 621 (1936), pp. 20, figs. 12).—The author studied the relationship between the percentage of first-grade eggs produced during certain seasons of the year and "per cent firsts" for the entire year from approximately 1,500 Single Comb White Leghorn pullets entered in the New Jersey egg-laying contests. The record year has been divided into three parts, namely, the winter season from October 1 to January 31, the spring season from February 1 to May 31, and the summer-fall season from June 1 to September 21. Frequency distribution tables, the degree of correlation for winter-year, spring-year, summer-fall-year, winter-summer-fall, and January-year "per cent firsts", and regression equations for predicting the yearly performance from any of the above-described short-time records are presented. In each instance the "per cent firsts" shown for a particular season was found to be positively and highly significantly correlated with the "per cent firsts" produced throughout the first laying year, with an indication that a prediction of the "per cent firsts" for the year based on "per cent firsts" in winter, in January, in spring, and in summer-fall would be 36, 45.4, 61, and 55.8 percent better than pure guess. It appears that the weighing of eggs for at least a 30-day period at any time after the layers have passed the third month of production may be used as a reasonable measure of the individual bird's egg-size quality character.

Augmentation of nitrogen to the egg white after the formation of the shell membranes in the fowl. H. M. SCOTT, J. S. HUGHES, and D. C. WARREN (*Poultry Sci.*, 16 (1937), No. 1, pp. 53-61).—In a study at the Kansas Experiment Station the absolute nitrogen content of laid eggs (each representing the first of a clutch) from 13 hens was compared with that in immature eggs from the same individuals (each representing the second egg of the same clutch intercepted in the isthmus). It was found that the immature eggs contained an

average of 96 percent as much nitrogen as the laid eggs, although the former contained only 51 percent by weight as much white as the latter.

By determining the total nitrogen in the consecutively laid eggs from 8 hens it was shown that the second-laid egg of a clutch averaged only 90 percent as much nitrogen as the first egg of the same clutch. It is concluded that differences in the nitrogen content of immature and laid eggs as noted by Pearl and Curtis (*E. S. R.*, 26, p. 670) were due entirely to the effect of clutch position and not to any infiltration of protein through the shell membrane. It is pointed out that according to the laws of physical chemistry protein would not pass from the uterine secretion of low protein concentration through the shell membrane into the egg white of higher protein concentration.

Loss of weight of hen's eggs during incubation under different conditions of humidity and temperature, E. M. PRINGLE and H. G. BAROTT (*Poultry Sci.*, 16 (1937), No. 1, pp. 49-52, fig. 1).—In tests conducted by the U. S. D. A. Bureau of Animal Industry, in which eggs were incubated in respiration calorimeters under carefully controlled conditions, loss of weight of fertile eggs during incubation was found to depend principally upon the relative humidity of the surrounding atmosphere. Rate of loss decreased in direct proportion to the increase in humidity within the tested range of from 8 to 85 percent at a constant temperature of 102° F.

When incubation temperatures were varied from 96° to 102.5° at a constant relative humidity of 60 percent a range of 96° to 99° had but slight effect on loss of egg weight, but at temperatures from 99° to 103.5° the weight loss became progressively greater with each degree rise in temperature, the total loss at the latter temperature averaging one-third greater than at the former. The daily loss of weight increased as incubation proceeded. A slight inverse relation was found between weight of eggs and loss of weight.

Blood chemistry of the chick embryo during ontogenesis, C. M. ZORN and A. J. DALTON (*Soc. Expt. Biol. and Med. Proc.*, 35 (1936), No. 3, pp. 451-453).—Values for blood sugar, uric acid, cholesterol, hemoglobin, and red blood cells in the blood of chick embryos by one-day intervals from the ninth to the twentieth day of incubation and from the first to the fourth day of postincubation are presented in tabular form and briefly discussed.

Electric brooding, J. C. TAYLOR and W. C. KRUEGER (*New Jersey Stas. Hints to Poultrymen*, 24 (1936-37), No. 2, pp. 4, fig. 1).—Certain practices which should be observed in the operation of an electric chick brooder are outlined.

DAIRY FARMING—DAIRYING

[**Dairy cattle and dairy products investigations in Iowa**] (*Iowa Sta. Rpt.* 1936, pt. 1, pp. 70-72, 73, 74, 86-88, 116-126).—Breeding and feeding studies reported include the consequences of inbreeding in Holstein-Friesian cattle, by J. L. Lush, C. Y. Cannon, and E. N. Hansen; the persistency and inheritance of milk and fat production among cows in Iowa cow-testing association herds, by Lush and E. N. Schultz; the relation of vitamin E to sterility (in goats), by Cannon, D. L. Espe, B. H. Thomas, and S. H. McNutt; the value of soybean gruel for calves, by Cannon, Espe, and Thomas; a comparison of roughages and the relation of roughage to grain in dairy cow rations, by Cannon, Hansen, and Espe; and storing hay with a modified silage cutter and a hay fork, by Cannon, Espe, Hansen, and E. V. Collins.

Studies with dairy products yielded results on the influence of the acidity in cream on fat losses in buttermilk, the kinds of acids in butter and the distribution of these acids between the water and fat phases, the effect of

neutralizers on fat losses in buttermilk and the quality of the butter, and the causes of tallowy flavor and other defects in strawberry ice cream, all by E. W. Bird; *Pseudomonas fragi* as a cause of rancidity in butter, micro-organisms causing surface taint in butter, the germicidal property of milk for *Streptococcus lactis*, the importance of acetylmethylcarbinol and diacetyl in butter cultures, the development of butter cultures from mixtures of organisms and with reference to mail shipment, and the classification of the organisms important in dairy products, all by B. W. Hammer; the nitrogen metabolism of *Lactobacillus casei* cultures important in Cheddar cheese made from pasteurized milk, and the protein and fat metabolism of various strains of *Penicillium roqueforti* used in Iowa blue cheese, both by C. B. Lane and Hammer; the production of 2,3-butylene glycol in dairy products, by Hammer and C. H. Werkman; the manufacture and introduction of a special-type Swiss cheese, by E. F. Goss and M. Mortensen; and a comparison of sediment tests for cream and butter, by L. A. Harriman and Bird.

[Dairy cattle investigations at the North Louisiana Substation] (*Louisiana Sta., North Louisiana Sta. Bien. Rpt. 1935-36, pp. 21-23*).—Brief results are noted on the profitability of dairying and feed production as supplements to cotton farming, the value of different cereals and vetch for winter grazing and of Sudan grass, kudzu, soybeans, and sweetpotato vines as summer grazing crops, feeding trials with chopped sweetpotatoes, dried sweetpotato pulp, and other feeds, and the effect of certain fertility treatments on permanent pasture results, all by S. Stewart and R. H. Lush.

[Dairy investigations in New Mexico] (*New Mexico Sta. Rpt. 1936, pp. 50, 51, 52*).—Projects previously noted (E. S. R., 75, p. 98) have been continued, with progress reported on the physiological effect of a hegari fodder and cottonseed meal ration on dairy cows and the vitamin A content of the butterfat produced.

Dairy cattle judging, A. B. NYSTROM (*U. S. Dept. Agr., Farmers' Bul. 1769 (1937), pp. 11-30, figs. 21*).—This supersedes Miscellaneous Circular 99 (E. S. R., 57, p. 371).

Effect of breed, size of cow, yield of milk, and stage of lactation upon efficiency of milk production, J. EDWARDS (*Jour. Dairy Res. [London], 7 (1936), No. 3, pp. 211-221, fig. 1*).—Based on an analysis of 2,400 2-day production records of cows, representing 12 dairy breeds as entered at the London Dairy Shows between 1922 and 1934, it is shown that among the best representatives of the various breeds there is little difference in the gross efficiency of milk production (the ratio of energy in the milk to the energy in the digestible nutrients consumed). Within a breed there is a tendency for gross efficiency to decrease with increase in live weight. Cows are more efficient than heifers. Cows milked three times daily are more efficient than those milked twice daily, and a steady decline in efficiency with advance of lactation was noted.

A comparison between blood meal and wheat gluten as a supplement to a low protein diet for dairy cows, S. BARTLETT (*Jour. Dairy Res. [London], 7 (1936), No. 3, pp. 222-227*).—Two groups of five milking cows each were employed in a double reversal feeding trial to compare blood meal (a lysine-rich protein) and wheat gluten (a lysine-poor protein) as supplements to a basal ration relatively low in protein and lysine content. These supplements were fed at approximately 2-percent levels in the concentrate ration, so that the low lysine group received from 9.9 to 10.8 g of lysine per gallon of milk produced while the high lysine group received approximately 20 percent more. Little difference was noted in the milk production obtained from the two rations, the slight advantage of the blood meal ration over the wheat

gluten ration failing to approach statistical significance. There was a small and almost significant advantage in live weight gains in favor of the former ration.

An experiment on substitution of ammonium bicarbonate for foreign oil cake protein in feeding milk cows on beet silage [trans. title]. P. EHRENBERG and V. PRIETWITZ (*Landw. Vers. Sta.*, 125 (1936), No. 1-2, pp. 101-118).—In a trial with two groups of milking cows, each receiving approximately the same total dry matter and starch equivalent in their rations, one group was given a supplement of 100 g of ammonium bicarbonate per head daily while the other received 0.5 kg of a mixture of soybean, peanut, and cottonseed cakes. The former group produced about 15 percent less milk than the latter group. A slightly higher percentage of butterfat in the milk of the group receiving the ammonium bicarbonate was the only significant difference noted in the composition of the milk from the two groups.

Utilization of vitamin A by dairy cows, G. S. FRAPS, O. C. COPELAND, R. TREICHLER, and A. R. KEMMERER (*Texas Sta. Bul.* 536 (1937), pp. 26).—In the first of the experiments reported 3 groups of 3 Jersey cows were fed rations containing such quantities of yellow corn and alfalfa meal as to provide 7,000, 170,000, and 340,000 Sherman-Munsell units of vitamin A per cow daily for the respective groups. Butter samples were collected at intervals over a 17-week period, and the vitamin A potency of the butter and of the feeds was determined in Sherman-Munsell units by rat assay.

At the beginning of the trial butter samples contained from 43 to 62 units of vitamin A and from 9.7 to 16.7 p. p. m. of carotene, while at the end of 17 weeks these values had decreased to 4, 12, and 10 units of vitamin A and 0.4, 3.9, and 3.6 p. p. m. of carotene for the 3 groups, respectively. The apparent percentage recovery was greatest at the beginning of the trial and for the cows receiving the least amount of vitamin A in the feed, which was due to the use of large proportions of the carotene and vitamin A stored in the body of individuals by the cows receiving the low carotene intake.

Correcting for the vitamin A potency stored by the cows by methods as outlined, the utilization was from 2.35 to 2.67 percent for an average of the periods. The carotene and spectro-vitamin A content of the individual butter samples indicated that some cows have a greater power than others to secrete vitamin A and carotene into the butter. A. I. V. sorghum silage was low in carotene and had little effect upon the carotene and vitamin A in the butter when fed to cows previously depleted. When 2 cows previously depleted were placed upon pasture the vitamin A potency of the butter increased from 12 units per gram to 40 or 50 units per gram within 3 days. The potency of the butter from cows on pasture was high, reaching a maximum of 72 units with one cow and 101 units for the other. The vitamin A potency of butter is closely related to the vitamin A potency of the feed and the period the cow has been receiving it. It is estimated that from 750,000 to 1,400,000 Sherman-Munsell units are required per cow per day to produce butterfat containing from 65 to 95 units per gram.

A note on feeding vitamin A and D concentrate in cod-liver oil to calves, A. C. DAHLBERG and L. A. MAYNARD (*Jour. Dairy Sci.*, 20 (1937), No. 1, pp. 59-61; *abs. in Farm Res. [New York State Sta.]*, 3 (1937), No. 3, pp. 1, 8).—In a trial at the New York State Experiment Station over a 40-week growth period, there was no apparent advantage of adding vitamin A and D cod-liver oil concentrate to a dairy calf ration consisting of 2.5-percent milk, skim milk, grain, and liberal amounts of alfalfa hay. The fact that the experimen-

tal calves without vitamin supplement were more thrifty than the general run of calves raised in the station herd is attributed to the greater consumption of alfalfa hay by the former group.

Raising the dairy calf, H. A. HERMAN (*Missouri Sta. Bul.* 377 (1937), pp. 28, figs. 11).—This is a popular bulletin on calf raising, successive sections dealing with care of the newborn calf, methods of raising the dairy calf, including feeding plans where skim milk is available and where milk substitutes must be used, suggestions on general management of calves, and the feeding and management of young dairy stock.

The composition of the colostrum of the dairy goat, A. J. BERGMAN and C. W. TURNER (*Jour. Dairy Sci.*, 20 (1937), No. 1, pp. 37-45, figs. 2).—This contribution from the Missouri Experiment Station reports the composition of colostrum and the trend of the various constituents in the transition to normal milk of 6 goats. Daily samples were analyzed over 9-day periods, and the analytical procedures are described. All of the constituents showed a rapid decrease in percentage during the second day except lactose, which increased. The colostrum closely approached normality between the third and fourth days. Globulin and albumin were determined separately in this study, and a very rapid decrease in the globulin is noted following removal of the first milk from the udder, while only a moderate decline occurred in the albumin.

Measuring the thickness of thin, flowing, liquid films, H. H. BECK and K. G. WECKEL (*Indus. and Engin. Chem., Analyt. Ed.*, 8 (1936), No. 4, pp. 258, 259, figs. 3).—This describes a new method for determining the thickness of flowing liquid films. The method utilizes the principle that some light is reflected from any surface and that the angles of incidence and reflection are equal. When a beam of light is projected on the surface of the film at an angle of 45° the distance between the parallel beams reflected from the surface of the film and from the metal surface supporting the film may be used as a basis for calculating the thickness of the film. The method, developed primarily to determine the thickness of milk films subjected to ultraviolet irradiation, has been found sufficiently sensitive to determine variations in the thickness of the film, such as those caused by changes in velocity, within successive short intervals.

Film characteristics: Effect on response of fluid milk to ultraviolet radiation, H. H. BECK and K. G. WECKEL (*Indus. and Engin. Chem.*, 28 (1936), No. 11, pp. 1251-1254, figs. 7).—Employing a light beam reflecting method as described above, the authors have determined the thickness, velocity of flow, and travel time of controlled thin flowing films of milk passing over a metal surface. Empirical formulas are presented for expressing these values as power functions of the film capacity (pounds per foot per hour). The character of the finish of the metal affects the thickness and other characteristics of the flowing film, and the degree of inclination of the surface also affects the film thickness. In a study of the relation between the thickness, velocity, and travel time of the film to the antirachitic potency acquired by the milk from ultraviolet radiation, it is shown that vitamin D potency is directly proportional to the travel time, thus emphasizing the importance of time in the irradiation of milk.

Milk: Effect of different sources of radiant energy on flavor and antirachitic potency, K. G. WECKEL, H. C. JACKSON, R. HAMAN, and H. STEENBOCK (*Indus. and Engin. Chem.*, 28 (1936), No. 6, pp. 653-656, figs. 3).—These experiments, conducted at the Wisconsin Experiment Station, represent an attempt to determine what part of the spectrum of various available sources of ultraviolet are particularly instrumental in producing an "activated flavor"

in irradiated milk. Three sources of radiant energy were employed, namely, the carbon arc (including five types of carbon electrodes), the quartz mercury-vapor arc, and the cold-quartz arc. Identical milk samples were irradiated until a uniform intensity of flavor was produced when the energy from each source was transmitted through quartz and through glass. There was a marked variation in the time required and the total energy expended from the different sources of irradiation to produce a uniform flavor change, and a like variation in the degree of antirachitic potency acquired by the milk was noted. It is shown that the flavor changes are caused by that part of the spectrum known to have an antirachitic effect as well as to parts of the spectrum devoid of such properties. The data indicate that within a spectral range below 3,100 a. u. the energy in wave lengths less than 2,600 a. u. is more active in flavor production than wave lengths between 2,600 and 3,100. Similarly, in a spectral region from 3,100 to 7,000, radiations of from 3,100 to 3,800 are more active in this respect than those from 3,500 to 7,000 a. u.

The rate of change in the vitamin A content of milk, W. C. LOX, J. H. HILTON, J. W. WILCOX, and S. M. HATGE (*Jour. Dairy Sci.*, 20 (1937), No. 1, pp. 31-36, fig. 1).—The object of this experiment at the Indiana Experiment Station was to determine the time required for the carotene and vitamin A content of milk to reach an equilibrium level when cows were changed from a high vitamin A ration to one of low vitamin A value and vice versa. Two Guernsey cows were fed an alfalfa hay, corn silage, and grain ration (high vitamin A) for 30 days, then changed to a ration of timothy hay, corn silage, and grain (low vitamin A) for a 21-day period, and then back to the original ration for an additional 21-day period. Butter was churned from milk samples at frequent intervals, chemically analyzed for carotene, and biologically assayed for vitamin A. During the depletion period the carotene and vitamin A in the milk fat declined rapidly, reaching an equilibrium level in about 11 days. During the repletion period the rise in these ingredients was rapid, reaching a constant level in 10 days. It is concluded that the major effect of a change in the diet on the vitamin A content of cows' milk can be ascertained by relatively short feeding trials.

Variations in the vitamin C content of milk, C. H. WHITMAN and W. H. RIDDELL (*Jour. Dairy Sci.*, 20 (1937), No. 1, pp. 9-14).—In further tests at the Kansas Experiment Station of factors causing variations in the vitamin C content of milk (E. S. R., 75, p. 245) the ascorbic acid content of the milk of from 40 to 58 individual cows in the station herd has been determined on three consecutive days of each month from October through April, with most of the animals receiving a typical winter ration without access to pasture.

Significant variations were noted between morning and evening milk samples and also from day to day, indicating that the vitamin C content of milk for a given cow or herd cannot be adequately determined by a single test. The level of production, age of the animals, and access to green feed are each shown to have only a slight effect, while season of the year, the individuality and breed of the cow, and the stage of lactation appear to be the most important factors causing variation in the vitamin C content of fresh milk from well fed cows.

A study of the seasonal variation of vitamin D in normal cow's milk, H. E. BECHTEL and C. A. HOPPEST (*Jour. Nutr.*, 11 (1936), No. 6, pp. 537-549, figs. 3).—Samples of milk from Holstein and Guernsey herds were assayed monthly for a period of 2 yr., and assays were made on butter samples during a 1-yr. period. The herds were kept under parallel conditions regarding sunshine and the ingestion of sun-cured feeds. A method is given for the

concentration of the antirachitic factors in milk fat so that fats of low potency can be biologically assayed.

The results obtained demonstrate that the antirachitic potency of milk may vary as much as 900 percent over a 2-yr. period, reaching a maximum from June to September, and, beginning with October, declining rapidly to a minimum in February. The vitamin D values ranged from 4.8 to 43.8 U. S. P. units per quart of Guernsey milk and from 3.1 to 27.7 U. S. P. units per quart of Holstein milk.

The amount of exposure of the cows to sunlight would appear to be the most important contributing factor as to the variability of the vitamin D content of milk. The vitamin D contained in dairy feeds apparently contributed very little to the potency of the milk. The cow has little or no opportunity to store vitamin D during lactation under ordinary dairy management conditions. The results of the bio-assays on the butter samples indicate that vitamin D in milk fat is stable for at least 30 mo. when stored at 0° F. in the dark.

Factors affecting the activatability of milk with ultra-violet light, W. E. KRAUSS, R. M. BETHKE, and R. G. WASHBURN (*Jour. Dairy Sci.*, 19 (1936), No. 12, pp. 739-747).—The Ohio Experiment Station has studied the effect of varying butterfat contents, various feeding conditions, including winter feeding v. pasture feeding, high protein rations v. low protein rations, and A. I. V. silage v. alfalfa hay, and breed on the degree of vitamin D enrichment attainable in milk through ultraviolet light irradiation. All samples were assayed by the standard line test procedure with rats.

In general, as the butterfat content of mixed herd milk increased (range from 0.025 to 6.3 percent), the capacity for vitamin D enrichment increased. The activatability of milk produced under various feeding practices, when standardized to a uniform butterfat content and irradiated under comparable conditions, is determined primarily by the original vitamin D potency of the unirradiated samples. Samples of Holstein and Jersey milks, either standardized to the same fat content or unstandardized, were activated to about the same degree of potency, suggesting that the solids-not-fat of Holstein milk may contain more activatable material than that of Jersey milk.

Amylase in cow's milk, G. A. RICHARDSON and C. L. HANKINSON (*Jour. Dairy Sci.*, 19 (1936), No. 12, pp. 761-772).—This study at the California Experiment Station produced evidence that normal cow's milk possesses starch liquefying, starch dextrinizing, and starch saccharifying activity. Based on the assumption that α -amylase accelerates starch dextrinization while β -amylase induces saccharification, milk apparently carries both α - and β -amylase. While considerable variation is noted between the activity of milk from different individuals, in general milk having high saccharifying activity also has high dextrinizing power. Milk from mastitis-infected udders shows greater diastatic activity than normal milk. The α fraction is partially inactivated by heating to 55° C. for 30 min., whereas the β fraction is completely stable when heated at 65° for 30 min. In testing for potency of these fractions an incubation temperature of from 30° to 40° or the former and 50° for the latter is considered optimum.

Variations in the phosphomonoesterase content of the milk of the cow in relation to the progress of lactation, S. J. FOLLEY and H. D. KAY (*Encymologia*, 1 (1936), No. 1, pp. 48-54, figs. 9).—This report is based on the determination of the concentration of phosphatase in 540 milk samples from Dairy Shorthorn cows and 104 samples from Guernsey cows, the samples

representing all stages of lactation for each breed. The output of phosphatase varied regularly throughout lactation, rising to a maximum at about 180 days post partum. The typical milk phosphatase concentration-lactation period curve is shown to be qualitatively the inverse of the milk yield-lactation period curve. No such regular changes occur in the phosphatase content of the blood serum with advance of lactation, indicating that the milk enzyme does not come directly from the blood. There is further indication that the rate of secretion of phosphatase in milk is in general inversely related to the functional efficiency of the mammary gland.

The fate of acetylmethylcarbinol and diacetyl in dairy products, G. L. STAHLX, B. W. HAMMER, M. B. MICHAELIAN, and C. H. WERKMAN (*Iowa Acad. Sci. Proc.*, 42 (1935), pp. 73-76).—In a series of tests in which either tomato bouillon or skim milk containing citric acid was inoculated with cultures of citric acid fermenting streptococci, incubated at 21° C. for from 24 to 48 hr. and then received additions of either acetylmethylcarbinol or diacetyl, it was found that both these substances were rather rapidly reduced to 2,3-butylene glycol. Increasing the acidity of the medium, adding certain hydrogen acceptors as sodium fumarate or hydrogen peroxide, and reducing the holding temperature each tend to reduce the rate of reduction, whereas neutralizing the cultures and holding at 21° results in very rapid reduction.

The relation of the oxidation-reduction potential of milk to oxidized flavor, R. E. WEBB and J. L. HILEMAN (*Jour. Dairy Sci.*, 20 (1937), No. 1, pp. 45-47, figs. 7).—Employing an improved type of platinum electrode, the construction of which is described, the authors have made oxidation-reduction potential determinations on a large number of milk samples and ascertained the relation of these values to the degree of oxidized flavor developing in the milk.

In a series of milk samples from individual cows drawn and pasteurized in glass containers, the absolute value of the oxidation-reduction potential appeared to have no relation to the degree of oxidized flavor which developed.

Samples of winter mixed herd milk coming in contact with exposed copper in the processing equipment were highly susceptible to the development of oxidized flavors. This was due to or accompanied by an increase in the oxidation-reduction potential of the milk to a point sufficiently high to bring about a change in some milk constituent. Summer mixed herd milk processed in the same equipment showed approximately the same degree of increase in reduction potential as winter milk but resisted the development of oxidized flavors. The exact cause for the reduced susceptibility of summer milk was not determined by this study, but apparently is not due to bacterial action. Winter milk processed in new equipment free from exposed copper areas did not show a marked increase in oxidation-reduction potential and failed to develop oxidized flavor in most instances, leading to the conclusion that mixed herd milk will rarely develop oxidized flavors unless contaminated with copper or some other agent that will raise the oxidation-reduction potential. Measurements of oxidation-reduction potential are considered a delicate means of detecting the source of copper contamination in a milk plant.

The "transition point" of milk fat, G. A. RICHARDSON (*Jour. Dairy Sci.*, 19 (1936), No. 12, pp. 749-752, fig. 1).—This contribution from the California Experiment Station describes a technic employed in determining the transition point in milk fat, i. e., the temperature at which a second phase begins to separate from a molten fat. Nine typical cooling curves for different fat samples are presented, primarily illustrating the influence of various feeding

practices on the transition point. Certain constants for these fat samples are given, from which it is evident that the cooling curve yields an insight into the physical and chemical nature of the fat.

Why do fat tests vary? A perpetual query, J. C. MARQUARDT and H. L. DURHAM (*Farm Res. [New York State Sta.], 3 (1937), No. 3, p. 15*).—Concluding this series (*E. S. R.*, 76, p. 844), data are reported indicating that the cream adhering to the sides of the cans does not alter the composition of the sample taken from the milk weigh vat as compared with the fresh milk sample or one taken directly from well-stirred milk in the can before dumping. Neither did the storage temperature to which milk was subjected before sampling affect the test. It is concluded that from 20 to 200 comparisons are sufficient to establish the accuracy of the routine method of sampling for any given installation. It is desirable that each installation be checked to establish its correctness for proper sampling of milk for fat analysis, since such factors as shape of the weigh can, type of strainer, etc., vary from plant to plant.

Manual for milk and cream testers in Maryland, C. W. ENGLAND (*Maryland Sta. Bul. 401 (1936), pp. 113-164, figs. 15*).—This bulletin describes methods for determining the butterfat content and other miscellaneous tests on dairy products, presents general information for testers, and sets forth the specifications for Babcock glassware and the dairy inspection law of Maryland.

Begin studies on paper milk containers, R. S. BREED (*Farm Res. [New York State Sta.], 3 (1937), No. 3, pp. 7, 14*).—Certain problems relating to the use of single service paper milk containers, with particular reference to methods for preventing bacterial contamination, and desirable sanitary standards for such containers are discussed.

Cleaning dairy equipment with trisodium phosphate, L. A. ROGERS and F. R. EVANS (*Jour. Dairy Sci.*, 19 (1936), No. 12, pp. 733-738).—This report from the U. S. D. A. Bureau of Dairy Industry shows that dairy equipment, such as separator parts, milking machine parts, and homogenizers, may be satisfactorily cleaned and sterilized by rinsing the parts in clean water, keeping them submerged in a 5-percent solution of trisodium phosphate from one period of use to the next, and rinsing in clean water before reassembling. Data are presented to indicate that the addition of 3 percent of sodium chromate to the trisodium phosphate entirely prevented corrosive action of the solution on tin plate, while additions of from 1 to 20 percent of either sodium perborate or sodium metasilicate to the phosphate reduced but did not prevent corrosion.

A study of the churn cleaning methods used by plants producing butter of various yeast and mold counts, H. A. BENDIXEN (*Jour. Dairy Sci.*, 20 (1937), No. 1, pp. 15-25).—This report from the Washington Experiment Station presents the results of a survey of methods employed in cleaning the churns in 17 cooperating creameries in the State and the yeast and mold counts of butter samples submitted by the respective plants. Good churn-cleaning methods are shown to be definitely related to low yeast and mold counts in butter. When the plants were grouped according to the median yeast and mold counts of butter samples the average butter score both when fresh and after 1 month's storage at from 36° to 41° F. decreased, and the average score loss during storage increased as the median yeast and mold counts increased.

Factors relating to the keeping quality of butter, O. R. OVERMAN (*Natl. Butter and Cheese Jour.*, 27 (1936), No. 24, pp. 6, 7).—The keeping quality of 36 different lots of stored butter, representing a wide range as regards the condition of cream from which the butter was churned, has been determined by the Illinois Experiment Station. It is concluded that neither the judges'

score of a butter sample, the chemical and physical constants of the butter, nor the rates of oxidation in butter are correlated with its keeping quality. On the basis of the initial score and ability to hold score, sweet cream butter is ranked first, followed by butter from starter ripened and partially neutralized cream, which in turn is superior to butter from spontaneously soured cream neutralized to the same acidity. Little difference was noted in the effect of different neutralizers used on initial score or keeping quality, while overneutralization resulted in low initial score and low keeping quality. In unneutralized cream butter, keeping quality declined with increased acidity. Salted sweet cream butter had a higher initial score but lost score more rapidly than unsalted sweet cream butter, samples of the latter being of salable quality after 2 yr. in storage.

Observations on yeasts causing gas in sweetened condensed milk, H. C. OLSON and B. W. HAMMER (*Iowa State Col. Jour. Sci.*, 10 (1935), No. 1, pp. 37-43, fig. 1).—This report deals with the types of yeast isolated from eight samples of gassy sweetened condensed milk. All samples yielded an oval yeast identified as *Torula lactis-condensi*, the characteristics of which are extensively described. Two of the samples also yielded a spherical yeast which is described and for which the name *T. globosa* is suggested. Apparently the former organism or the two growing together are commonly the cause of gas formation in sweetened condensed milk. When the two species are growing together the former is invariably the more numerous. Certain factors which may cause failure to secure gas formation when these organisms are inoculated into normal sweetened condensed milk are discussed.

First hand observations on cheese making in Germany, J. C. MARQUARDT (*Farm Res. [New York State Sta.]*, 3 (1937), No. 3, pp. 10, 11, figs. 3).—This article gives a brief résumé of the present status of the cheese industry in Germany, with a note on the trends in cheese research in that country.

The importance of the fat globule membrane in the freezing of ice cream, C. D. DAHLE and D. V. JOSEPHSON (*Ice Cream Rev.*, 20 (1937), No. 6, pp. 60, 62, 64, 66, 68, 70, 71).—In an investigation at the Pennsylvania Experiment Station to determine the reasons for the relatively poor whipping properties of ice cream mixes made from butter, butter oil, frozen cream, and plastic cream, it is shown that the whipping ability of such mixes is directly related to the degree to which the mixes "oil off" during processing. This condition is probably the result of foreign membranes being established on the surface of the newly formed fat globules during reemulsification. These membranes are a mixture of all the surface-tension-active substances in the mix, many of which are not conducive to good whipping. As a result of incorporating various emulsions of butter and butter oil into mixes, using a butter-fat "membrane suspension", egg yolk, egg or milk phospholipids, skim milk, buttermilk, vegetable lecithin, and starch, respectively, as emulsifying agents, it is concluded that the presence of a protein-phospholipid complex or membrane, such as that supplied by the egg yolk or membrane suspension, on the surface of the fat globules in the mix is essential for normal whipping properties.

VETERINARY MEDICINE

[Contributions on animal pathology] (*N. Y. State Vet. Col. Rpt.*, 1934-35, pp. 46-154, pls. 12).—Contributions relating to animal physiology, pathology, parasitology, etc., here presented (*El. S. R.*, 74, p. 539) are as follows: The Correlation of Anatomy and Epidural Anaesthesia in Domestic Animals, by G. S. Hopkins (pp. 46-51); A Non-Alcoholic Bromthymol Blue Solution, by C. El.

Hayden and S. D. Johnson (p. 52); Chemical Examination of the Blood and Chemical and Morphological Examination of the Urine (pp. 53-62) and Calcium Metabolism and Therapy (pp. 63-74), both by C. E. Hayden; The Acid-Base Balance in Cows and Ewes During and After Pregnancy, With Special Reference to Milk Fever and Acetonemia, by J. Sampson and C. E. Hayden (pp. 75-82) (E. S. R., 72, p. 692); Recent Progress in the Physiology of Digestion, by H. H. Dukas (pp. 83-89); Urinary Calculi, by H. J. Milks (pp. 90-96); Urinary Antiseptics, by H. C. Stephenson (pp. 97-101); A Study of *Gastrophilus* spp. Infestations of Horses in New York State, by D. W. Baker (pp. 102-110); Bovine Trichomoniasis, by H. S. Cameron (pp. 111-119) (E. S. R., 73, p. 685); Bang's Disease of Cattle, by R. R. Birch and H. L. Gilman (pp. 120-137); Recovery From John's Disease: Report of a Case, by W. A. Hagan and A. Zeissig (pp. 138-141) (E. S. R., 73, p. 849); and Vaccination Against John's Disease (pp. 142-149) (E. S. R., 74, p. 696) and The Relationship of Certain Diseases of Cows to Disease in Man (pp. 150-154), both by W. A. Hagan.

Annual report of the veterinary service for the year 1935, R. J. ROE (*Cyprus Dept. Agr. Ann. Rpt., 1935, pp. 37-49*).—The work of the year is briefly reported upon (E. S. R., 74, p. 694).

[Report of work with livestock diseases], W. C. BARRY, C. S. M. HOPKIRK, ET AL. (*New Zeal. Dept. Agr. Ann. Rpt., 1935-36, pp. 19-23, 27-33*).—The occurrence of and work of the year with diseases of livestock are reported upon.

A spot method of conducting whole-blood agglutination tests with stained antigen, D. E. STOVER (*North Amer. Vet., 18 (1937), No. 1, pp. 17-19, 20, fig. 1*).—A description is given of a simple method for conducting whole blood tests with stained antigen by which ill effects appear to be overcome to a marked degree.

How selective is the habitat of the poisonous *Astragalus hylophilus*? E. H. GRAHAM (*Ecology, 18 (1937), No. 1, pp. 171, 172*).—A critical discussion of the contribution of Beath previously noted (E. S. R., 76, p. 533).

[Contributions on parasites of animals] (*Jour. Parasitol., 22 (1936), No. 6, pp. 528-530, 531-533, 534, 535, 536, 537, 538-540, 541, 542, 543, 544, 545*).—Contributions presented at the twelfth annual meeting of the American Society of Parasitologists (E. S. R., 74, p. 694) held at Atlantic City, N. J., in December 1936, abstracts of which are presented, include the following: Parasites of Equines in the Panama Canal Zone, by A. O. Foster (p. 528); *Elaeophora poelli* Railliet and Henry 1912 in African Buffalo and Its Taxonomic Affinities, by J. H. Sandground (p. 528); Morphological and Biological Studies on *Tetrameres crami* Swales 1933, an Important Nematode Parasite of Ducks, by W. E. Swales (p. 528) (E. S. R., 76, p. 398); The Value of Esophageal Structures in Nemic Classification, by B. G. Chitwood (p. 528); The Fecundity of Single *Strongyloides ratti* Parasites, by G. L. Graham (p. 529); Effects of Various Physical Factors on the Survival of Eggs and Infective Larvae of the Swine Nodular Worm *Oesophagostomum dentatum*, by L. A. Spindler (p. 529); The Effect of Tropical Sunlight on Eggs of *Ascaris suis*, by L. A. Spindler (pp. 529, 530); Diagnosis and Treatment of Intestinal Parasitism by the Intra-Intestinal Thermal Method, by D. de Rivas (p. 531); Further Studies in Ascarid Nutrition, by J. E. Ackert and A. E. Freeman (p. 531), contributed from the Kansas Experiment Station; Observations Upon the Glycogen Relationships in *Ascaris*, by T. v. Brand (pp. 531, 532); Retention of Guanidine Bases, A Toxic Factor in Trichinosis, by P. D. Harwood, J. T. Cutler, L. A. Spindler, and S. X. Cross (p. 532); A Relationship in Equines Between Age of Host and Number of Strongylid Parasites, by A. O. Foster (p. 532); Studies on Trichinosis—I, The Inci-

dence of Trichinosis as Indicated by Post-Mortem Examination of 300 Diaphragms, and II, Some Correlations and Implications in Connection With the Incidence of Trichinae Found in 300 Diaphragms, both by M. C. Hall and B. J. Collins (pp. 532, 533); Studies on Active Acquired Resistance, Natural and Artificial, in the Rat to Infection With *Strongyloides ratti*, by A. J. Sheldon (p. 533); A Cerebral Coenurus From *Cercopithecus nictitans*, by J. H. Sandground (pp. 533, 534); Some New Cercariae From *Planorbis pfeifferi*, *Melanoides tuberculata*, and *Pseudoglossula boivini*, by A. Porter and H. B. Fantham (p. 534); The Pathology of Two Trematode Infections of *Lymanea natalensis*, by H. B. Fantham and A. Porter (pp. 534, 535); The Occurrence of *Eurythmus squamula* (Rudolphi 1819) in the United States, by A. McIntosh (p. 536); The Specific Validity of the Human and Pig *Ascaris*, Based on a Comparative Study of Spermatogenesis and Oogenesis, by L. S. Ritchie (p. 536); Experimental Infestations of Rats and Mice With *Capillaria hepatica*, by G. W. Luttermoser (pp. 536, 537); Effect of Irradiated Ergosterol on Trichinized [*Trichinella spiralis*] White Rats, by W. W. Wantland (pp. 537, 538); Effect of Irradiated Ergosterol and Irradiated Milk on Calcification of Trichina Cysts in Cats, by W. W. Wantland, C. Hansen, and R. E. Feeney (p. 538); Exposure of Three Endoglobular Bovine Parasites [*Anaplasma marginale*, *Babesia argentina*, and *B. bigemina*] to Different Degrees of Temperature, by C. W. Rees (pp. 538, 539); A Twenty-Four Hour Asexual Cycle in a New Strain of *Plasmodium praecox* (*relictum*), by F. Wolfson (p. 539); The Cultivation of *Trichomonas foetus* Free From Bacteria, by J. Andrews (p. 539); *Trichomonas columbae* as a Cause of Death in the Hawk, by R. M. Stabler and H. A. Shelanski (pp. 539, 540); Experimental Amoebiasis in Rats With Cysts of Human Carriers, by H. Tsuchiya (p. 540); The Louse Fly *Lynchia fusca* Parasite of the Owl, *Bubo virginianus pacificus*, a New Vector of Malaria of the California Valley Quail, by W. B. Herms and C. G. Kadner (p. 541); The American Dog Tick or Eastern Rocky Mountain Spotted Fever Tick, by F. C. Bishopp and C. N. Smith (pp. 541, 542); Equine Encephalomyelitis in Western Montana in 1936—A Brief Discussion of the Implications of Arthropod Transmission, by C. B. Philip and H. R. Cox (p. 542); The Life History of *Diphyllobothrium mansonoides*, by J. F. Mueller (p. 543); The House Fly and Fowl Tapeworm [*Choanotaenia infundibulum*] Transmission, by J. E. Ackert and W. M. Reid (p. 543); Progress of Spirochaete Infection in the Developmental Stages of the Host Tick, *Ornithodoros hermsi* Wheeler, by C. M. Wheeler (p. 544); Experimental Studies on the Trematode *Parorchis acanthus* Nicoll, by R. M. Cable (p. 544); and Experimental Studies on *Neascus vancouveri*, by M. S. Ferguson (pp. 544, 545).

Studies on the bionomics and control of the bursate nematodes of horses and sheep.—III, Further observations on the toxicity of urine and some related substances for sclerostome larvae in feces, I. W. FARRELL (*Canad. Jour. Res.*, 14 (1936), No. 11, Sect. D, pp. 172-180, figs. 5).—In continuation of the studies previously noted (E. S. R., 76, p. 392), comparative tests with cow urine have shown that there is considerable variation in its lethal effect on horse sclerostome larvae in manure. "Urine gradually loses its lethal power over a period of months and is useless after a year. Tests on urines of various farm animals are also recorded, as well as on fluid from byres and manure heaps. The chemical composition of urine is discussed, and tests with ammonia and acetone on larvae are described."

Studies on intestinal parasites among wild rats caught in Saint Louis. H. TSUCHIYA and L. E. RECTOR (*Amer. Jour. Trop. Med.*, 16 (1936), No. 6, pp. 705-714).—The findings in 100 rats (*Mus norvegicus* and *M. rattus*) caught in 16 different locations in the city of St. Louis are recorded. The study is

considered to justify the conclusion that wild rats are probably an important factor in human infections with *Hymenolepis nana* and *H. diminuta*, that *Trichinella spiralis* may probably be transmitted from rat to swine and hence to humans, and that these rats may be looked upon as a reservoir for *Endamoeba histolytica*. A list of 21 references to the literature is included.

Anaplasmosis, E. R. DERFLINGER (*North Amer. Vet.*, 17 (1936), No. 10, pp. 24-26).—A report based upon cases observed in Oregon.

A study of blackleg and its complications, F. BREED (*Jour. Amer. Vet. Med. Assoc.*, 90 (1937), No. 4, pp. 521-528).—It is concluded that blackleg, of which *Clostridium chauvei* is the true cause when uncomplicated, may in the field be caused by *C. chauvei* combined with *C. septicus*, and in a few instances, with *C. novyi*.

"From the clinical symptoms manifest and the gross lesions produced it is impossible to distinguish between those produced by *C. chauvei* and those complicated with *C. septicus*. The microscopic examination of affected material of unknown origin is not a reliable means of diagnosing *C. chauvei* infection. Further laboratory procedures should be used to prove the type of infection or infections. The recognized blackleg products marketed by commercial institutions having adequate and reliable scientific staffs will provide a high grade of protection against direct exposures to the organism *C. chauvei*. Efficient products prepared from *C. chauvei* will not give adequate protection to infections of *C. septicus* or *C. septicus* combined with *C. chauvei*. Lambs are susceptible to infections of the *C. chauvei* and *C. septicus* on direct exposure and are suitable animals for testing the efficiency of *C. chauvei* and *C. septicus* immunizing products. A product prepared in accordance with the method outlined by Scheuber [*E. S. R.*, 67, p. 70], or this same method with slight modifications as outlined, will yield a product which will give adequate protection to lambs and probably calves."

The 5-cc dose of *chauvei-septicus* bacterin contains sufficient active principals to protect lambs against a lethal-plus dose of *C. chauvei*, *C. septicus*, and a mixture of the two organisms.

A slow-drying antigen for the Brucella rapid agglutination test, I. F. HEDDLERSON (*Jour. Amer. Vet. Med. Assoc.*, 90 (1937), No. 4, pp. 519, 520).—Need for the introduction of a factor into the *Brucella* rapid agglutination test which will retard drying, since rapid drying of the serum-antigen mixture often interferes with the efficacy of the test, led to the preparation of the slow-drying antigen here considered. "The antigen is prepared according to the method previously described [*E. S. R.*, 72, p. 382] up to the point of determining the proportion of bacterial cells to suspending menstruum. After adjusting the antigen so that the volume of cells is 20 percent of the total volume of the suspending liquid, one-half of the total volume of the antigen is centrifuged again to sediment the cells completely. A quantity of the supernatant liquid equal to 20 percent by volume of the total volume of antigen is removed from the sedimented cells and replaced by glycerin (C. P.). The two parts of antigen then are mixed thoroughly and left standing for 24 hr. before determining its sensitivity to specific agglutinins according to the method previously described. The glycerinated antigen and undiluted serum mixtures dry slowly on the glass plate. Even after the mixture has dried completely the agglutinated particles of antigen remain very distinct, thus enabling the operator to read the results of the tests after many days with a high degree of accuracy."

Purified foot-and-mouth disease virus.—I, Studies on some of its physical properties, I. A. GALLOWAY and W. J. ELFORD (*Brit. Jour. Expt. Path.*,

17 (1936), No. 3, pp. 187-203, figs. 2).—In work conducted on behalf of the Foot-and-Mouth Disease Research Committee it was found possible "to make preparations of purified foot-and-mouth disease virus in buffered phosphate solution at pH 7.6 by repeated washing on collodion membranes of suitable porosity. These preparations gave a negative reaction in the test for proteins (sulfosalicylic acid test), and had a potency equivalent to the stock filtrates. The stability of purified virus in buffered phosphate solution over a period of about 3 days at 22° C., or 1 mo. at 0°, compared very favorably with that of unpurified virus. After much longer periods the loss in titer of the purified virus was somewhat greater than that of unpurified virus kept under the same conditions. Slight differences were observed in the stabilities of the various preparations of purified virus, doubtless attributable to varying degrees of 'purity' below the limiting concentration of protein detectable by the sulfosalicylic acid test. The purified virus differed from unpurified virus in (1) its relative instability in a digest broth medium, (2) its greater sensitiveness to the photodynamic action of methylene blue, and (3) its greater susceptibility to the lethal action of certain concentrations of alcohol. The filtration behavior of the purified virus suspended in a buffered phosphate medium at pH 7.6 was in every way similar to that of unpurified virus under the same conditions.

"Tests on the survival of purified foot-and-mouth disease virus at the critical pH values 3, 6, and 7.6 showed that, as in the case of the unpurified virus, two zones of relative stability may be demonstrated, separated by a region in which the virus rapidly becomes inactivated. The number of experiments made was not sufficient to decide definitely whether or not any slight alteration in relative stability is shown by the washed virus, but certainly there appeared to be no pronounced displacement of the pH zones of stability. Purified virus dried in vacuo remained infective for at least a week at -4° to 0°."

The transmission of influenza virus to hedgehogs, C. H. STUART-HARRIS (*Brit. Jour. Expt. Path.*, 17 (1936), No. 4, pp. 324-328, pl. 1).—The work reported has shown that the influenza virus from man will produce a mild respiratory infection in the hedgehog. "The condition is contagious and has been transmitted in series by direct inoculation through 10 hedgehogs. Recovery from the infection is accompanied by the development of antibodies in the blood, while the virus can no longer be recovered from the respiratory tract. There is no evidence that the hedgehog can develop an inapparent infection and can carry the virus for long periods. No opportunity has yet arisen to test the possibility of direct transmission from human beings with influenza to the hedgehog. Representatives of the Primates, the carnivores, and the rodents have been known for some time to be susceptible to influenza virus. . . . Influenza in the hedgehog resembles the disease as seen in the ferret rather than that in the mouse."

Observations on the effect of louping ill virus on the developing egg, F. M. BURNET (*Brit. Jour. Expt. Path.*, 17 (1936), No. 4, pp. 294-301).—The investigation has shown that louping ill virus may be propagated in the developing hen's eggs, producing both local chorioallantoic membrane lesions and general effects upon the embryo. "The number of focal lesions can be used, as a sensitive but rather inaccurate indicator of the presence and amount of virus. Serum neutralization tests can be carried out with the egg membrane as the indicator organism, the results agreeing fairly closely with those obtained by the method of intracerebral inoculation in mice. Virus is constantly present in the circulating blood, is in part at least attached to the blood cells, and is liberated from this attachment by the action of distilled water. The lesions observed in the embryo are such as might be accounted for

if the primary effect of this virus is to produce a hemolytic anemia with or without primary damage to liver cells. The almost exclusive viscerotropism of louping ill virus in this situation is discussed."

Rabies in the vampire bat of Trinidad, with special reference to the clinical course and the latency of infection, J. L. PAWAN (*Ann. Trop. Med. and Parasitol.*, 30 (1936), No. 4, pp. 401-422).—A further contribution on rabies in *Desmodus rotunda murinus* Wagn. (E. S. R., 76, p. 100), in which it is pointed out that this bat may become a carrier of rabies after recovery from the furious form of the disease and remain capable of spreading infection by its bites for prolonged periods.

Trypanosomiasis of stock in Mauritius.—III, The diagnosis and course of untreated *T. vivax* infections in domestic animals, A. R. D. ADAMS (*Ann. Trop. Med. and Parasitol.*, 30 (1936), No. 4, pp. 521-531).—A continuation of this contribution (E. S. R., 74, p. 849).

Mastitis, IV, V (*New York State Sta. Tech. Buls.* 239 (1936), pp. 16; 241 (1937), pp. 21).—A continuation of this series of studies (E. S. R., 75, p. 542).

IV. *The composition of milk as affected by latent mastitis*, A. C. Dahlberg, J. J. Kucera, J. C. Henning, and G. J. Hucker.—Work was undertaken to determine whether there is a demonstrable relationship between the degree of infection and the chemical composition of milk normal in appearance.

"Only cows having udders free from active inflammation and whose milk was normal in appearance were selected for study. These cows were divided into three groups, viz, (1) no demonstrable infection, (2) slight infection, and (3) pronounced latent infection but milk normal in appearance. Composite milk samples of complete milkings from each of these groups were submitted to detailed chemical analysis. During the course of the study samples of foremilk from each quarter of each cow were studied by bacteriological tests to determine the amount of infection present. Only slight differences in the chemical composition of the mixed milk of these groups were found, regardless of the degree of infection, as long as the milk remained normal in macroscopic appearance. The slight differences in chemical composition included a decrease in lactose, specific gravity, skim milk solids, and curd tension, while the chlorides and albumins were slightly increased. These changes in composition were not greater than variations in chemical composition of milk between two herds of the same breed.

"It is concluded that milk normal in appearance is essentially normal in chemical composition. If no milk is included from inflamed, congested, or injured quarters, the chemical composition of the milk from a herd will be normal in chemical composition. It follows that earlier investigations on the chemical composition of normal milk were not affected by the possible presence of latent mastitis."

V. *The presence of mastitis streptococci in bovine mammary tissue*, G. J. Hucker.—In further studies, the details of which are given in tables, an examination of 24 udders, aseptically removed and cultured, from cows known to be free of the disease and to have passed through one or more lactation periods showed that all contained mastitis streptococci. A similar study made of 21 udders removed from virgin heifers and calves indicated that less than half contained mastitis streptococci in the mammary tissue.

Frequency of mastitis by quarters, F. B. HADLEY (*Jour. Amer. Vet. Med. Assoc.*, 90 (1937), No. 4, pp. 532, 533).—In a study made of 400 udder quarters showing well-marked evidence of mastitis, the 2 rear quarters were found more often affected with mastitis than the 2 front quarters, but there was no significant difference in the occurrence of the disease between the right and

the left halves of the udder. When the 2 front quarters were compared with each other and the 2 rear quarters were similarly compared, only a little difference was noted. Of the 153 affected front quarters, 18.5 percent of the right and 19.75 percent of the left were involved; of the 247 affected rear quarters, 30.5 percent of the right and 31.25 percent of the left were involved.

Clinical results in the treatment of so-called functional sterility of cows, C. F. CLARK (*Jour. Amer. Vet. Med. Assoc.*, 90 (1937), No. 4, pp. 488-492).—The author concludes from the limited number of cases reported in this contribution from the Michigan Experiment Station that douches of physiological saline solution and ovarian massage were of value in treating some cases of so-called functional sterility. The use of ovarian extracts in a few cases did not show conclusive value. There was no conclusive evidence that a nutritional factor was involved, received by grazing animals and withheld from those stabled.

Staphylococcal infections of the bovine udder, R. GWATKIN, S. HADWEN, and H. M. LEGBARD (*Canad. Pub. Health Jour.*, 27 (1936), No. 8, pp. 391-400, figs. 2).—In examinations made of the milk of 260 cows, comprising milk from individual quarters of 236 animals in 8 herds and 24 cows received from other herds on account of udder trouble, 143 cases of mastitis were detected. "Ninety-four were infected with streptococci and 4 with other bacteria. In 15 the cause was not determined, while in 30 staphylococci were incriminated. Twenty of the 30 cases of staphylococcal mastitis occurred in 2 herds in which staphylococci were the only pathogenic organisms isolated. Swelling or induration was detected in 21 of these animals in one or more quarters. Fourteen of 18 cows in 1 herd were affected. The milk of all was abnormal by the bromothymol-blue or rennet test, and the udders of 12 showed indurations. Therefore, in addition to its occurrence in sporadic cases, staphylococcal mastitis also occurs as a herd infection. Two cases were severe, and one of these had a fatal termination. The other animals showed no constitutional disturbance at time of examination.

"One hundred and thirty-one cultures of staphylococci from udders were examined. All fermented lactose. Five failed to ferment maltose. Forty-six strains fermented glycerol. Ninety-four fermented mannitol. Only 5.3 percent of the mannitol positive strains were isolated from apparently normal udders, and 46 percent of the mannitol negative strains came from this source. Toxin was produced in semisolid medium by 41 of 80 strains tested. Thirty-one were mannitol negative and 10 of these produced toxin (32.2 percent). Forty-nine were mannitol positive and 31 of these produced toxin (63.2 percent). Three of 44 filtrates proved fatal for guinea pigs by intracardiac injection. No relationship was observed between toxin production and clinical severity. Toxin was produced by 67.4 percent of the strains recovered from cases of staphylococcal mastitis and from 20 percent of the strains from normal udders. A strain of *Staphylococcus aureus* producing a small highly colored colony persisted in one quarter of an udder for 6 mo. The other quarters yielded the commoner type of this organism. There was no admixture of strains. The small colony type was a stronger toxin producer than the others. Attention is drawn to work which suggests the possible public health importance of staphylococcal mastitis."

Sheep diseases, F. E. HULL and W. W. DIMOCK (*Jour. Amer. Vet. Med. Assoc.*, 90 (1937), No. 4, pp. 469-478).—A practical summary of information from the Kentucky Experiment Station, presented at the annual meeting of the American Veterinary Medical Association at Columbus, Ohio, in August 1936.

Enzootic abortion in ewes.—A preliminary note, J. R. GREIG (*Vet. Rec.*, 48 (1936), No. 42, pp. 1225-1227).—A description is given of a form of enzootic abortion in ewes. The conditions of the occurrence of the disease suggest that it is associated with local environmental factors.

The efficiency of commercial lamb dysentery serum, R. F. MONTGOMERIE and W. T. ROWLANDS (*Vet. Rec.*, 48 (1936), No. 50, pp. 1481-1483).—A report is made of an investigation of the antitoxic value of five commercial brands of lamb dysentery serum, two of British and three of foreign origin. "One British and one foreign brand contained antitoxins capable of neutralizing the toxin produced by *Cl[ostidium] welchii*, type B (the lamb dysentery bacillus), in all its growth phases. One British brand was distinctly deficient in antitoxin capable of neutralizing one of the main toxic fractions of *C. welchii*, type B, and two foreign brands contained no detectable antitoxin."

The control of the lesser stomach worm in sheep, D. ROBERTSON (*Scot. Jour. Agr.*, 19 (1936), No. 4, pp. 359-363).—The treatment of lambs with copper sulfate and nicotine sulfate, carbon tetrachloride, and copper sulfate and arsenic in capsule or tablet form had no effect on *Ostertagia* spp. It is concluded that the low nutritive value of pastures in autumn will hinder the progress of lambs and render them more susceptible to parasitic infestation. In the treatment of ostertagiasis greater reliance should be placed on the provision of concentrates than the administration of anthelmintics.

The nematodes and certain other parasites of sheep, S. B. FREEBORN and M. A. STEWART (*California Sta. Bul.* 603 (1937), pp. 75, figs. 17).—The authors have prepared a practical summary of what is known of the life history of the various nematode and a few other parasites affecting sheep, together with methods of treatment. Tables for the separation of the forms considered, their synonymy, notes on their biology, etc., are included.

Studies on the toxicity of blighted barley to swine, J. J. CHRISTENSEN and H. C. H. KERNKAMP (*Minnesota Sta. Tech. Bul.* 113 (1936), pp. 28, figs. 3).—Of the many plant pathogens associated with blighted barley in Minnesota which are toxic to swine, species of *Alternaria*, *Helminthosporium*, and *Fusarium* were the fungi most commonly isolated. There were striking differences in the prevalence of these fungi on different lots of blighted barley from different localities in the same year and also from the same locality in different years. Barley distinctly blighted by *Fusarium* came from the southern part of the State only.

"The relative toxicity of different lots of grain was determined by making a water extract and administering it to pigs orally via stomach tube. An extract of 15 g (about ½ oz.) of scabby kernels was sufficient to make a pig weighing 100 lb. vomit. Sterile extracts made from scabby barley and injected intravenously and intraperitoneally caused the pigs to sicken. Extracts from pure cultures of *Fusarium* spp. grown on various substrata were not toxic to pigs. However, pure cultures of *Fusarium*, *Alternaria*, *Chaetomium*, and *Penicillium*, *Helminthosporium*, and bacteria, when grown on steamed barley, were refused by pigs unless mixed with other food.

"It was demonstrated by feeding tests with pigs that *Fusarium graminearum* produces a toxic principle in wheat, barley, and corn if inoculated at time of grain formation. The toxic principle may persist in whole barley for at least 3 yr. It is water soluble and thermostable. The amount of toxic principle present in scabby barley usually is proportional to the degree of shriveling. Many of the most toxic kernels can be removed by fanning thoroughly or by immersing the grain in water and then skimming off the blighted seeds that float on the surface.

"Feeding tests were made with 23 lots of barley graded either scabby or blighted and with 5 lots of sound barley (controls). Barley blighted primarily with *Helminthosporium* and *Alternaria* was not toxic to pigs, although it contained as much as 31 percent by weight of blighted kernels. The feeding value of barley was reduced considerably when 10 percent of scabby kernels were added to sound barley. Barley naturally infected with 16 percent scab was extremely toxic to pigs, while pigs refused to eat barley with 32 percent scab infection by weight.

"Pigs affected with *Fusarium* poisoning lose their appetites, become listless, weak, sometimes vomit, and may even die. An overdose of an extract of *Fusarium*-infected corn caused the death of two pigs. There is some indication that the toxic extract of scabby barley may be somewhat detoxicated under certain conditions by the addition of milk, starch, and other materials. Some of the toxic principle can be removed by soaking and washing the infected grain."

It is pointed out that these investigations indicate a need for further information on the utilization of scabby barley as feed for swine.

A list is given of 23 references to the literature cited.

Production of so-called alkali disease in hogs by feeding corn grown in affected area. H. W. SCHOENING (*North Amer. Vet.*, 17 (1936), No. 9, pp. 22-28, figs. 4).—A report is made of two typical cases of so-called alkali disease produced in hogs by feeding corn grown in an area where the disease has occurred naturally. "The symptoms and lesions produced in the experimentally fed hogs were typical of those seen in hogs naturally affected in certain areas of the Great Plains States. Symptoms of the disease began to appear a few weeks after the beginning of experimental feeding of corn from the alkali disease area. Symptoms became more severe with continued feeding of such corn.

"Chemical analysis of the corn indicated that selenium is a responsible factor in the production of the condition. Both lots of corn grown in the affected area contained selenium, one in the proportion of 10 p. p. m., the other 5 p. p. m., whereas no selenium was found in the normal or control corn. Furthermore, the two hogs which became affected were fed on the lot of corn containing the largest amount of selenium (10 p. p. m.)."

Effect of ferrous sulphate and copper sulphate on experimental infection of pigs with the nodular worm, *Oesophagostomum dentatum*, L. A. SPINDLER (*North Amer. Vet.*, 17 (1936), No. 12, pp. 29-32).—The results in four tests of the daily administration of 3.7 cc of a dilute aqueous solution of ferrous sulfate and copper sulfate to pigs infected experimentally with the nodular worm *O. dentatum* are reported upon. "The experimental pigs had been farrowed and raised indoors and were all suffering from secondary or nutritional anemia at the beginning of the tests. In all of the tests the pigs receiving the iron-copper solution gained weight more rapidly and were in better physical condition at the termination of the tests than were the control pigs. In spite of the fact that the test pigs remained in better physical condition than the controls, the former were infested in each case with a greater number of nodular worms at necropsy than the pigs that did not receive iron and copper."

A study of the blood-grouping factors in horses, V. A. HERMAN (*Jour. Immunol.*, 51 (1936), No. 5, pp. 347-353).—A study conducted by the Ukrainian Institute of Experimental Medicine, Kharkov, is reported. "A comparison of the species- and group-specific agglutinins in the blood of the horse and of man has demonstrated a resemblance between the blood groups of the two

species, not only in regard to the interagglutinative mechanism but also in regard to the group factors, agglutinins and agglutinogens, themselves. After removal of the species-specific agglutinins by adsorption, both human serum and horse serum showed group-specific agglutination of either human erythrocytes or horse erythrocytes. This reciprocal interaction shows the similarity of the agglutinogens and agglutinins in man and in the horse. Certain internal organs of the horse contain group components corresponding to those of the blood. The similarity of the group factors in man and the horse, and the quantitative differences in agglutinative titer are interesting biologically, and suggest the desirability of similar systematic comparisons of the blood of other species. Our studies furnish a systematic basis for a nomenclature of equine blood groups."

A list of 40 references to literature is included.

Equine encephalomyelitis in Panama, R. A. KELSEY ([*War Dept. U. S.*], *Off. Surg. Gen., Vet. Bul.*, 31 (1937), No. 1, pp. 19-21).—This report of encephalomyelitis in an artillery horse at Fort Clayton, C. Z., from which the eastern type of the virus was isolated, is said to be the first record of its occurrence in Panama. The 10-year-old horse in which the disease appeared was born and raised in Nebraska and shipped to the Canal Zone in 1930.

Pyosepticemia of foals due to *Bacillus abortivo equinus*, R. T. SEYMOUR ([*War Dept. U. S.*], *Off. Surg. Gen., Vet. Bul.*, 30 (1936), No. 4, pp. 277-282).—It is concluded that even when the most rigid sanitary measures are practiced, pyosepticemia of foals on farms where equine infectious abortion has recently occurred may be due to prenatal infection and perhaps more frequently to postnatal infection with *B. abortivo equinus*. It is pointed out that the symptoms and pathological changes noted on autopsy closely resembled many of the other types of infections of foals. There appears to be no accurate clinical differentiation of this type of infection from other infections of foals.

Verminous aneurysm in equines of Panama, A. O. FOSTER and H. C. CLARK (*Amer. Jour. Trop. Med.*, 17 (1937), No. 1, pp. 85-99, pls. 3).—Post-mortem studies of over 200 equines in Panama revealed an active verminous arteritis or aneurysm in about 80 percent of the cases. The disease was encountered in animals of all ages, in both native and imported stock, and in horses, mules, and burros. The typical lesion affected the anterior mesenteric artery and was characterized by tortuosity, sclerosis, thrombosis, and diminished caliber. Usually there were less than 10 worms—larvae of *Strongylus vulgaris*—in the lesions. Many of the animals covered in this survey were condemned because of unserviceableness, although a larger proportion was reasonably representative stock of this locality. The probable effect of verminous arteritis upon the efficiency of equines is emphasized, and the prerequisites for the type of control needed in this region are outlined.

A quantitative study of the nematodes from a selected group of equines in Panama, A. O. FOSTER (*Jour. Parasitol.*, 22 (1936), No. 5, pp. 479-510).—Data are presented on the qualitative and quantitative occurrence of nematode parasites recovered at autopsy from 48 horses and mules imported into the Panama Canal Zone and used by the U. S. Army.

Canine endoparasites, H. M. CORENZWIT (*North Amer. Vet.*, 17 (1936), No. 11, pp. 37-40, 41).—A report is made of the findings at autopsies performed in Philadelphia on 200 stray canines taken at random from among several thousand that were destroyed during a city-wide quarantine against rabies in January, February, and March 1936. Of the 86 percent that were found to be parasitized, 69.5 percent were infested with whipworms (*Trichuris vulpis*),

52 with tapeworms (*Dipylidium* and *Taenia* spp.), 17 with hookworms (*Ankylostomae*), 17 with large intestinal roundworms (*Ascaridae*), 14 with heartworms (*Dirofilaria immitis*), and 0.5 percent with an acanthocephalid (*Oncicola canis*).

A note on the occurrence of the heartworm, *Dirofilaria immitis*, in the eye of a dog, J. E. ALICATA and R. H. MORRISON (*North Amer. Vet.*, 17 (1936), No. 11, pp. 41, 42).—A report of an observation of the heart worm in Hawaii.

Skin scabies or mange of the fox, P. J. G. PLUMMER (*Canada Dept. Agr. Pub.* 502 (1936), pp. 8, pl. 1, figs. 2).—A practical account of the itch mite, the only acarid found to parasitize foxes in Canada, the nature of the affection resulting from its parasitism, and preventive and control measures.

Diectophyme renale in mink, E. F. GRAVES (*Jour. Amer. Vet. Med. Assoc.*, 90 (1937), No. 4, pp. 531, 532, fig. 1).—This is a case report of a 1-year-old male mink, the death of which was caused by the kidney worm of carnivores.

[Work in avian pathology by the Iowa Station] (*Iowa Sta. Rpt.* 1936, pt. 1, pp. 94, 95, 146-148).—The work of the year with diseases of poultry briefly referred to (E. S. R., 75, p. 102) includes the etiology of range paralysis and the egg as a possible mode of its transmission, both by C. Murray, C. D. Lee, and H. L. Wilcke; breeding for resistance to fowl typhoid, by W. V. Lambert and N. F. Waters; and genetic investigation of resistance and susceptibility to typhoidlike diseases in laboratory animals, by Lambert.

Studies on certain filtrable viruses.—I, Factors concerned with the egg propagation of fowl-pox and infectious laryngotracheitis, C. A. BRANDLY (*Jour. Amer. Vet. Med. Assoc.*, 90 (1937), No. 4, pp. 479-487).—The susceptibility of the developing avian egg to infection, the inoculation of eggs of various species with infectious laryngotracheitis virus, factors influencing the infectivity or virulence of fowl pox and of laryngotracheitis virus for developing eggs, and the effect of continued egg passage upon infectivity and filtrability of the viruses are considered in this contribution, the author's findings being based upon work conducted in part at the Kansas Experiment Station and in part by the division of animal pathology and hygiene, University of Illinois.

It is concluded that the finding of variations in susceptibility to infection among different species, as well as within the species of egg employed, may bear considerable significance. Various factors influence the infective potency or virulence of fowl pox and infectious laryngotracheitis viruses insofar as continued egg propagation is concerned, and failure to recognize such factors may complicate the application of the relatively simple technic of developing egg cultivation of the viruses.

The immunological relationship between Kikuth's canary virus and fowl-pox, F. M. BUENET and D. LUSH (*Brit. Jour. Expt. Path.*, 17 (1936), No. 4, pp. 302-307).—The authors have found that the viruses of fowl pox and Kikuth's canary disease can be accurately titrated by the pock-counting method on the chorioallantoic membrane. Cross-neutralization tests indicate that the two viruses, though not identical, are serologically very closely related. There is no cross reaction with vaccinia virus.

Attenuation of the fowl pest virus by X-ray [trans. title], B. S. LEVIN and I. LOMINSKI (*Compt. Rend. Acad. Sci. [Paris]*, 203 (1936), No. 3, pp. 287, 288).—The authors have found that the pathogenicity of the fowl pest virus can be completely attenuated by X-ray irradiation at a dosage of from 1.5 to 2 million r-units.

The etiology of fowl paralysis, leukemia, and allied conditions in animals, V, VI, M. W. HAMMEL (*Florida Sta. Bul. 305 (1936), pp. 66, figs. 4*).—The continuation of this contribution (E. S. R., 75, p. 547) is presented in two parts.

V. *The oral exposure of chickens infected with various species of Eimeria (Coccidia) to Salmonella aertrycke* (pp. 5-44).—Experiments are reported which show that the inflammation created by coccidia in the intestinal tract of the chicken creates an avenue of infection for the causal micro-organism, in the present case *S. aertrycke*.

"The single intravenous injection of *S. aertrycke* into 20 8-weeks-old parasite-free birds resulted in one case of fowl paralysis. The repeated daily oral exposure of parasite-free 10-weeks-old birds to *S. aertrycke* for periods of 30 and 90 days resulted in hemocytoblastosis but no other pathologic manifestation. The single oral exposure of 20 parasite-free 2-weeks-old chicks to *S. aertrycke* resulted in one case of fowl paralysis. The repeated (three doses) oral exposure of 20 parasite-free 2-weeks-old chicks to the same causal micro-organism resulted in two cases of fowl paralysis and one case of lymphatic erythroleucosis. The oral exposure of birds previously artificially parasitized to *E. praecox*, *E. necatrix*, and *E. maxima* and two groups of naturally parasitized birds affected with mixed coccidial infection to *S. aertrycke* resulted in a high percentage of cases of the pathologic manifestations, i. e., fowl paralysis, 'light' and anemia, lymphomatosis, and leukemia. Fifty-two of 90 birds so exposed developed one of the pathologic manifestations, more cases developing in naturally parasitized birds than in the ones artificially parasitized.

"Two experiments are reported which indicate that partial recovery or recovery from hemocytoblastosis results in a certain degree of immunity and that exposure shortly thereafter to *S. aertrycke* failed to cause a development of pathologic manifestations even though the birds were affected with a mixed coccidial infection at the time of exposure to the causal micro-organism. There was a relative increase in the length of the incubation period with advancement in age. The incubation period for fowl paralysis varied from 17 to 63 days, lymphomatosis from 45 to 104 days, erythroleucosis from 73 to 91 days, myeloid leukemia from 81 to 104 days, and light and anemia 14 days."

VI. *The oral exposure of chickens infested with Ascaridia, Taenia, and Capillaria to Salmonella aertrycke* (pp. 45-63).—Sixty-two of 98 birds that were orally exposed to *S. aertrycke* during chronic intestinal parasitism by *Ascaridia*, *Taenia*, and *Capillaria* developed one of the pathologic manifestations, 5 others developed a complication of two manifestations, and 24 control birds remained normal. "The incubation period for fowl paralysis was 29 to 57 days, lymphomatosis 52 to 85 days, light and anemia 18 days, myeloid leukemia 70 to 172 days, and erythroleucosis 86 to 171 days. Four complicated cases of fowl paralysis and leukemia developed in 54 to 86 days, while one case of fowl paralysis and lymphomatosis developed in 58 days."

The details of this contribution in 18 tables and a list of 44 references to the literature cited are included.

Leucemia of fowls, C. A. BRANDLY, R. GRAHAM, and V. M. MICHAEL (*Illinois Sta. Circ. 467 (1937), pp. 14, figs. 10*).—A practical account of leukemia which has, during the last few years, become one of the most serious diseases affecting poultry flocks in Illinois. It is pointed out that, while chickens of all breeds and ages are susceptible to the disease, the largest percentage of infections has been observed in birds between the ages of 2 and 18 mo. Leukemia occurs in both acute and chronic forms and is usually fatal. The symptoms

and lesions are highly variable, making diagnosis difficult in many cases. Prevention is based upon general sanitary measures of disease control.

Studies of incubation factors in the agglutination test for pullorum disease. H. M. DeVOLT and C. R. DAVIS (*Maryland Sta. Bul.* 402 (1936), pp. 165-176).—A report is made of a study of some incubation factors in the tube agglutination test for pullorum disease as regards the possible effect of variations in incubation methods, including manner of heating the tubes, incubation temperature, and length of the incubation period.

The work has led to the conclusion that convection currents induced by warm spots on the bottom or sides of a test tube are responsible for the failure of plain antigen suspensions and negative tests to settle out when placed close to the heating elements of an incubator or on a warm surface.

"This effect was sufficiently strong to cause slight inhibition of the agglutination reaction in 65 percent of a group of tests placed in the small incubator at 37.5° C. Inhibiting of the test became more pronounced with the rise in temperature. The speed of the reaction was increased at temperatures of 45° and 55° but not at 37.5°, 65°, or 75° in the small incubator. Cloudy reactions occurred to a marked extent at 65°. The effect of time was at a minimum in changing the interpretation of tests after the 24-hr. reading."

Intradermal avian tuberculin test in ducks. J. F. CRAIG and G. O. DAVIES (*Vet. Rec.*, 49 (1937), No. 2, pp. 29, 30).—The tests of ducks with avian tuberculin here reported have led to the conclusion that the tuberculin test as applied intradermically to the web of the duck's foot is of no practical value in the diagnosis of tuberculosis.

AGRICULTURAL ENGINEERING

Report of committee on engineering experiment stations, Association of Land-Grant Colleges and Universities, at meeting of engineering section in Houston, Texas, November 1936 (*Assoc. Land-Grant Colls. and Univs., Engin. Expt. Sta. Rec.*, 17 (1937), No. 1, pp. 8-12).—This report contains statistical data relating to full and part time personnel and funds available at the engineering experiment stations during the fiscal year 1936-37 and funds available at the agricultural experiment stations for engineering research for the same period.

[**Agricultural engineering investigations by the Iowa Station**], H. GIESE, J. B. DAVIDSON, E. V. COLLINS, Q. C. AYRES, E. G. MCKIBBEN, C. K. SHEED, A. A. BRYAN, P. E. BROWN, and H. R. MELDRUM (*Iowa Sta. Rpt.* 1936, pts. 1, pp. 46-51, fig. 1; 2, pp. 20-24).—Progress results are briefly presented in part 1 of investigations on farm fires and the effectiveness of spark arresters, the all-masonry barn, equipment for checkrowing beets, soil erosion control, utilization of clay products in farm building construction, and the kinematics and dynamics of transport wheels used on agricultural equipment; in part 2 of investigations of the basin method of growing corn, a dual pneumatic tire attachment for use on a tractor when cultivating corn, accuracy of the four-row checkrowers, wagon and trailer hitches with telescoping tongues, efficiency of experimental snapping rolls for corn pickers, a disk joiner for seedbed preparation, comparative merits of a plow, a pulverator, and disk harrow and duckfoot type cultivators for seedbed preparation, and spacing distances for checked corn.

Surface water supply of the United States, 1935, Parts 5, 6, 9 (*U. S. Geol. Survey, Water-Supply Papers* 785 (1936), pp. 283, pl. 1; 786 (1936), pp. 353, pl. 1; 789 (1937), pp. 174, pl. 1).—These papers present the results of

measurements of flow made on streams during the year ended September 30, 1935, No. 783 covering the Hudson Bay and upper Mississippi River Basins, No. 786, the Missouri River Basin, and No. 789 the Colorado River Basin.

Daily river stages at river gage stations on the principal rivers of the United States, compiled by M. W. HAYES (*U. S. Dept. Agr., Weather Bur., Daily River Stages*, 33 (1935), pp. III+162).—This volume contains data for 1935 (E. S. R., 75, p. 111).

Water, its use and control in Kansas: An outline (*Topeka: Kans. State Planning Bd., 1936*, pp. 28, [figs. 14]).—This report of the Kansas State Planning Board presents a general picture of ways for the better utilization and control of water in the State and suggests steps that must be taken to bring about such betterments.

Water duty trials in the Sudan Gezira, H. GREENE (*3. Internatl. Cong. Soil Sci., Oxford, Eng., 1935, Trans., vol. 3, pp. 168-171, fig. 1*).—As a general summary of the experiments here briefly recorded, "it may be said that during the period of vigorous vegetative growth and increasing severity of climate, light or infrequent waterings are injurious, but heavy or frequent waterings, though conferring benefit on the crop, do not produce the large increase of yield that might be expected. It appears that the rather low permeability of Gezira soil sets at this stage a limit to the utilization of irrigation water, of which only a part sinks at all deeply into the soil while the rest remains on or near the surface and is more or less wasted. On the other hand, if water is abundant and cheap, there is practically no risk of reducing the yield by heavy irrigation."

Characteristics of transverse Pitot tubes, J. E. CHRISTIANSEN and O. C. FRENCH (*Agr. Engin., 18 (1937), No. 1, pp. 21-24, figs. 6*).—Tests made at the California Experiment Station on four transverse tubes of different sizes, an improvised Pitot tube, and a tube for determining static pressure are reported. The diameters of the transverse tubes varied from 0.125 to 0.3125 in., and the orifice diameters of all six tubes varied from 0.052 to 0.116 in.

Series A tests were made with both stuffing boxes screwed into tapped holes (0.25-in. pipe size) in the sides of the pipe. Series B tests were made with the stuffing boxes screwed into 0.25-in. pipe couplings soldered to the outside of the pipe 45° from the tapped holes. A test on the 0.3125-in. tube, series C, was made with the other 0.3125-in. tube in position 3 ft. 1.5 in. upstream. In this test the planes of the two tubes intersected at an angle of 45°. Another test, series D, was made with the improvised Pitot tube.

Negative pressures on the downstream side of transverse tubes were generally greater than positive pressures on the upstream side. Velocity transverses with the orifice upstream were identical for all tubes, regardless of size, and were similar to those obtained with an improvised conventional type Pitot tube. Mean velocities computed from these traverses agree with the end cap orifice measurement. Orifice-downstream traverses were affected by the position of the stuffing boxes with respect to the pipe wall. Mean velocities computed from these traverses approximate the velocities calculated from net pipe areas after deducting for areas occupied by the tubes.

Tests indicate that velocities determined from the mean head for orifice-upstream and orifice-downstream positions should be corrected for half the area occupied by the tube. Positions of mean velocity were found to average 0.78 of the radius from the center of the pipe. Average differences between velocities at 0.707 *R* and mean velocities were +3 percent for orifice-upstream traverses and +1 percent for mean-head velocity curves. Static pressure connections made by drilling holes through the pipe wall were not reliable before

the burrs were removed. A bushing screwed in a tapped hole gave erroneous results, but a static pressure tube inserted in a tapped hole proved satisfactory for static pressure determinations. When properly used, transverse Pitot tubes are reliable devices for measuring the flow of water in pipes. The tests indicate that measurements within 1 percent of the true discharge are possible.

Conservation of land and water resources of Nebraska, G. E. CONDRA (*Nebr. Univ., Conserv. and Survey Div., Conserv. Dept. Bul. 14* (1936), pp. 46, figs. 8).—This is a general discussion.

Public Roads, [March and April 1937] (*U. S. Dept. Agr., Public Roads, 18* (1937), Nos. 1, pp. [2]+23+[1], figs. 23; 2, pp. [2]+25-52+[1], figs. 24).—These numbers contain data on the various highway projects as of February 28 and March 31, 1937, respectively. No. 1 also contains an article entitled *The Theory of Soil Consolidation and Testing of Foundation Soils*, by L. A. Palmer and E. S. Barber (pp. 1-20), and No. 2, *The Effect of Vibration on the Strength and Uniformity of Pavement Concrete*, by F. H. Jackson and W. F. Kellermann (pp. 25-49).

Alcohol-gasoline as motor fuel, G. EGLOFF and J. C. MORRELL (*Indus. and Engin. Chem.*, 28 (1936), No. 9, pp. 1080-1088, figs. 9).—It is brought out in this contribution that alcohol-gasoline has no over-all technical advantages compared to gasoline. The increased fuel consumption of a 10-percent alcohol-gasoline blend is approximately 4 percent higher than gasoline alone, based on both road and block tests. The improvement in antiknock value and consequent efficiency when alcohol is added to gasoline (employing suitable design and operating conditions) is less than the decrease in efficiency as measured by fuel consumption. The over-all effect is an increased fuel consumption. The use of alcohol-gasoline introduces operating difficulties, especially in starting, acceleration, and vapor lock. The handling and shipment of alcohol-gasoline are difficult because of the ease with which these components separate when traces of water are introduced. It is difficult to keep water out of bulk or storage tanks, filling-station tanks, and motorcar tanks. The cost of alcohol-gasoline is much higher than gasoline alone.

Alcohol-gasoline blends, L. M. CHRISTENSEN (*Indus. and Engin. Chem.*, 28 (1936), No. 9, p. 1089-1094, figs. 4).—This contribution presents data to show that various types of alcohol blends are in common use in practically every country, the usual blends distributed commercially containing from 5 to 25 percent of ethanol or of methanol and ethanol. Anhydrous ethanol is miscible with gasoline in all proportions; methanol ordinarily requires the addition of a stabilizer, ethanol being entirely satisfactory for this purpose.

Properly prepared alcohol blends containing not more than about 25 percent of alcohol by volume may be used interchangeably with gasoline of equal antiknock rating. Such blends may safely be stored and distributed in modern commercial equipment. Used in this type of blend the alcohols are not substitutes for gasoline but serve the purpose of increasing the antiknock value and otherwise improving the fuel. It is on this basis that the value of these alcohols must be determined.

Engine performance with gasoline and alcohol, L. C. LICHTY and E. J. ZICKS (*Indus. and Engin. Chem.*, 28 (1936), No. 9, pp. 1094-1101, figs. 10).—This paper deals with the power, fuel consumption, and other performance characteristics of internal-combustion engines when using gasoline and ethyl alcohol as fuels. Theoretical analysis shows ideal possibilities ranging from 2.0 percent increase in power with gasoline compared to pure alcohol to 8.6 percent

increase with pure alcohol compared to gasoline, depending upon mixture conditions.

The water in 190-proof ethyl alcohol has a negligible effect on power but increases the specific fuel consumption about 6.6 percent, owing to lowered heating value per given quantity of fuel compared to pure alcohol. Tests on a variable-compression single-cylinder C. F. R. engine and on a 1935 Chevrolet engine under various conditions show a small average increase in power (not much more than experimental error involved) in favor of the 190-proof alcohol. However, the specific fuel consumption with 190-proof alcohol is about 60 percent higher on a weight basis and about 50 percent higher on a volume basis than with gasoline.

Utilization of ethanol-gasoline blends as motor fuels, O. C. BRIDGEMAN (*Indus. and Engin. Chem.*, 28 (1936), No. 9, pp. 1102-1112, figs. 4).—In this contribution from the Federal Bureau of Standards data are presented to show that blends containing ethyl alcohol have no material advantage over gasoline as motor fuels, although they can be utilized satisfactorily if full advantage is taken of the available technical information. Small percentages of ethyl alcohol in the blend are more advantageous than large percentages from the standpoints of maximum power and acceleration for minimum fuel consumption and of ease of engine starting and warming. The reverse is true from the standpoints of vapor lock and of water tolerance. A compromise may therefore be necessary from the technical standpoint in determining the composition of the blend most suitable for any particular purpose.

The alcohol used for blending should be essentially anhydrous in order to prevent separation of the alcohol in service. By employing a suitable blending agent the water tolerance of the blend can be markedly increased, although the ethyl alcohol used must still be practically anhydrous unless very large percentages of blending agent are employed.

Rothamsted measurements comparing fuel and electricity as a source of power, G. H. CASHEN and B. A. KEEN ([*Rothamsted Expt. Sta., Harpenden*], *Rothamsted Confs. No. 21* (1936), pp. 60-69).—These investigations had for their purpose to show, for typical farming operations, how many units of electricity are equivalent to 1 gal. of kerosene, gasoline, or heavy fuel oil. Threshing experiments with oats, wheat, and barley showed that for conditions at Rothamsted electricity is a cheaper form of power than fuel oil in a tractor. Feed-grinding experiments were in favor of a Diesel motor using fuel oil.

"Electric power—how to obtain it and how best to use it", M. M. HARVEY ([*Rothamsted Expt. Sta., Harpenden*], *Rothamsted Confs. No. 21* (1936), pp. 8-41).—The general purpose of this paper is to indicate how English farmers who are within reach of a public electricity supply may obtain the greatest benefits for their outlay of capital and to point out the general trend of electric farming development as related to the various types of farms.

Wiring and motors are briefly touched upon in their technical aspects, and general information is given on rates with particular reference to reasons for variations. The types of farms using electricity are tabulated with some specialized applications, and the various appliances are discussed at greater length. Other sections deal with private plants, the verdict of farmers already using electricity, some details of actual installations, tables of running costs, and other data collected from various sources and authorities.

Electric motors for farm machinery, F. E. ROWLAND ([*Rothamsted Expt. Sta., Harpenden*], *Rothamsted Confs. No. 21* (1936), pp. 42-53, figs. 14).—Technical information on motor adaptations to farm machinery is presented.

Farm wiring, C. A. CAMERON BROWN (*Oxford: Univ. Oxford, Inst. Res. Agr. Engin.*, 1935, pp. 32, pls. 4).—This is a semitechnical discussion of wiring systems with suggestions as to the most satisfactory for farm buildings.

Pneumatic equipment for farm tractors, A. HAY (*Rubber Growers' Assoc., Rubber and Agr. Ser. Bul. 1* (1936), pp. 18, figs. 12).—The use of pneumatic tires for tractors used in English farming is described and illustrated.

Pneumatic equipment for horse drawn vehicles, A. HAY (*Rubber Growers' Assoc., Rubber and Agr. Ser. Bul. 2* (1936), pp. 20, figs. 22).—Wagons and carts used on farms in England and equipped with pneumatic tires are described. Tests with carts showed that pneumatic tires permitted the carrying of heavier loads at a saving in time.

Methods of hedge and tree-stump clearing, T. SWARBRICK ([*Gt. Brit.*] *Min. Agr. and Fisheries Bul. 101* (1936), pp. V+16, figs. 11).—This brief account of methods now in use in England includes hand-operated and power pullers, explosives, and chemicals.

Safety in the handling and use of explosives (*U. S. Dept. Agr., Soil Conserv. Serv.*, 1936, R5-M8-5, pp. [5]+27, figs. 4).—Popular information on the subject is presented.

Water supply for orchards, B. A. JENNINGS (*N. Y. State Col. Agr., Cornell Ext. Bul. 367* (1937), pp. 30, figs. 22).—Technical information of a practical character is given on storage, pumping, and distribution of water for orchards.

A weed eradication program (*Reclam. Era* [U. S.], 27 (1937), No. 2, pp. 36, 37, figs. 2).—In this brief article a single blade weed eradicator is described and diagrammatically illustrated, and brief specifications are given.

The uses of rubber in commercial horticulture, A. HAY and D. F. C. VOSPER (*Rubber Growers' Assoc., Rubber and Agr. Ser. Bul. 6* (1937), pp. [1]+16, figs. 18).—These uses include pneumatic tires for garden tractors; rubber-jointed tracks for track laying type tractors; and rubber tires for spraying equipment, wheelbarrows, and planting and harvesting equipment.

The uses of rubber in stable management, A. HAY (*Rubber Growers' Assoc., Rubber and Agr. Ser. Bul. 5* (1936), pp. [1]+14, figs. 14).—Uses of rubber, such as for stall floors and walls, collars, saddles, horseshoes, and stable barrows, are briefly described and illustrated.

The care and cleaning of milking machines, A. HAY (*Rubber Growers' Assoc., Rubber and Agr. Ser. Bul. 4* (1936), pp. [1]+16, figs. 13).—Practical information is given on the subject.

Instruments for farm structures research, W. V. HUKILL (*Agr. Engin.*, 18 (1937), No. 2, pp. 59-61, figs. 2).—In a brief contribution from the U. S. D. A. Bureau of Agricultural Engineering some of the more important technical apparatus used in farm structures research is described.

Principles of heating, ventilating, and air conditioning, A. M. GREENE, JR. (*New York: John Wiley & Sons; London: Chapman & Hall*, 1936, pp. VII+446, figs. 254).—This handbook contains chapters on methods of application; properties and conditioning of air; loss and gain of heat through walls; radiators, valves, and heat transmission from radiators; method of calculating heat required for rooms; direct steam heating; hot water heating; indirect steam heating, air flow, and gravity systems; indirect steam heating, plenum system, and air conditioning; unit heaters and air conditioning; warm air furnace heating; furnaces, boilers, and heaters; automatic controls; and district heating.

Refrigeration for the farm and dairy, C. A. CAMERON BROWN (*Oxford: Univ. Oxford, Inst. Res. Agr. Engin.*, 1936, pp. 51, pls. 6).—This publication includes practical information on different types of small cooling plants, their methods of application, and differences in operation and running costs.

AGRICULTURAL ECONOMICS

[Investigations in agricultural economics by the Delaware Station, 1935-36] (*Delaware Sta. Bul.* 205 (1936), pp. 9-14, figs. 2).—Results in investigations not previously noted include findings by R. O. Bausman on 182 commercial poultry farms as to the effects of artificial lights on annual and seasonal production of eggs, costs, profits, size of eggs, etc., and by H. S. Gabriel in a study of retail marketing of apples as to seasonal demand for, relative prices of varieties, and competition of other fruits in 25 chain stores in Philadelphia.

[Investigations in agricultural economics by the Iowa Station, 1935-36] (*Iowa Sta. Rpt.* 1936, pts. 1, pp. 174-185, 186-189, 190, figs. 3; 2, p. 59-64, fig. 1).—Findings in investigations not previously noted are reported as follows: Part 1, by J. A. Hopkins, C. Malone, and C. Y. Cannon as to cash operating and fixed expenses, net farm income, etc., in 1935 on 71 farms in the northeastern dairy area of the State; by R. C. Bentley, T. W. Schultz, and W. G. Murray as to the number of farm sales and average sales price per acre in 11 counties from July 1934 to November 1935; by M. G. Reid as to the space devoted to different kinds of advertising in farm and general magazines and as to price differences in retail stores; by Schultz, R. Schickele, L. G. Allbaugh, W. W. Wilcox, and Hopkins as to average acreages of soil-depleting and soil-conserving crops and permanent pasture, and number of different kinds of livestock in 1933 on over 800 heavy grain, heavy grass, and average farms; by F. Robotka and P. E. Quintus in the study of the organization and membership of Iowa farmers' cooperative creameries; and by Schultz in the study of economic implications to Corn Belt agriculture of certain structural changes in foreign trade and in a study of the changes, 1929-33, in expenditures for different purposes on Iowa farms; and part 2, a chart by G. S. Shepherd showing the acreages and yields of corn, 1866-1935, and the acreages of wheat and hay, 1900-1935, in Iowa; findings by Bentley as to the rail and truck shipments and local sales of feed grains by eight elevators in Hamilton County; by Schultz as to the competitive position of American lard in foreign markets; and by Shepherd as to factors affecting the price of corn.

[Investigations in agricultural economics by the New Mexico Station, 1935-36] (*New Mexico Sta. Rpt.* 1936, pp. 13-16).—Investigations not previously noted are included, with general recommendations based on the study of adjustments in farming desirable to conserve soil and range resources made in cooperation with the U. S. D. A. Bureau of Agricultural Economics and Agricultural Adjustment Administration, and a table showing the relative importance of different sources of income in three pump irrigation sections of the State.

Current Farm Economics, [April 1937] (*Oklahoma Sta., Cur. Farm Econ.*, 10 (1937), No. 2, p. 25-47, figs. 3).—Included are articles on Use of Short-Term Credit by Farmers in Selected Oklahoma Counties, by L. S. Ellis (pp. 26-28); Is Farm Tenancy Inherently an Evil? Yes? No? Who Knows? (pp. 29-34) and The Livestock Situation (pp. 41, 42), both by P. Nelson; The Development of Credit Unions in Oklahoma (pp. 34-39) and General Situation (pp. 42-47), both by T. R. Hedges; and Some Results of Marketing Oklahoma Wool on Grade, by A. W. Jacob (pp. 39-41).

The importance of farm accountancy for the study of certain economic problems in agriculture, J. DESLARZES ([*Internatl. Rev. Agr.*], *Mo. Bul. Agr. Econ. and Sociol.* [Roma], 26 (1935), Nos. 2, pp. 41-54; 3, pp. 107-117).—Some examples are given of the contributions that may be made by the results of

farm accountancy in determining gross returns, earning capacity, advantages of different types of farming, etc.

Notes on the use of farm accountancy data in comparative economic inquiries, G. PAVLOVSKY ([*Internatl. Rev. Agr.*], *Mo. Bul. Agr. Econ. and Sociol.* [Roma], 26 (1935), No. 5, pp. 169-175).—The possible use of farm accountancy data is studied, and different types are discussed.

"Farm accountancy data, either obtained by the method of sampling or resulting from the monographic study of a small group of farms, cannot be used as the only source of material in agricultural economic research. Used as supplementary material they enrich the equipment of the student considerably by enabling him to gain insight into such aspects of the problems dealt with which would not be gleaned from any other sources."

Some observations concerning farm accountancy methods in the United States, J. DESLARZES ([*Internatl. Rev. Agr.*], *Mo. Bul. Agr. Econ. and Sociol.* [Roma], 27 (1936), No. 2, pp. 50-60).—This article embodies the results of a study from a methodological point of view of the accountancy results of the farms of Illinois, Iowa, and Indiana in 1932.

Costs and prices: Some factors of the evolution of mechanical power in farming, C. KAPPSTEIN ([*Internatl. Rev. Agr.*], *Mo. Bul. Agr. Econ. and Sociol.* [Roma], 26 (1935), No. 8, pp. 298-314).—A study is made of the relation of prices of coal, gasoline, electric current, etc., on the prices of agricultural products and the effect on the use of mechanical power in agriculture in Great Britain, Germany, the United States, and Italy.

Cost of production of beets, carrots, cauliflower, celery, cucumbers, egg-plant, lettuce, okra, peppers, radishes, spinach, squashes, and turnips, compiled by H. W. HAWTHORNE (*U. S. Dept. Agr., Bur. Agr. Econ., 1937, pp. [2]+58*).—Data for the years 1914-34 drawn directly or computed from Federal publications and those of State experiment stations and other agencies are presented.

A farm management study of 224 coffee farms in Puerto Rico, 1934, J. M. GARCÍA (*Jour. Agr. Univ. Puerto Rico* [Col. Sta.], 21 (1937), No. 1, pp. 29-67, figs. 2).—This is the complete report on the study previously noted (*E. S. R.*, 76, p. 412). An analysis is made of survey records from 224 coffee farms in 19 municipalities.

The average size of farms was 186 cuerdas (181 acres), of which 88.5 cuerdas were in coffee. Forty-two percent of the coffee bushes were under bearing age. The average investment was \$15,580 per farm, of which 83.4 percent was in land. The average labor income was —\$1,120, and only 9 percent of the farmers had a positive income, averaging \$414. Labor income was indirectly related to all measures of size of business and directly to measures of efficiency of operation. Owner-operated farms showed less loss than those operated through major-domos or salaried managers.

The financing of the growing and marketing of cotton, G. COSTANZO ([*Internatl. Rev. Agr.*], *Mo. Bul. Agr. Econ. and Sociol.* [Roma], 27 (1936), No. 1, pp. 1-39).—This article describes the systems of financing in the United States, India, Egypt, Union of Soviet Socialist Republics, China, Argentina, Brazil, Turkey, and other countries.

Cultivation of cotton in Spain, E. MARTINEZ DE BUJANDA ([*Internatl. Rev. Agr.*], *Mo. Bul. Agr. Econ. and Sociol.* [Roma], 27 (1936), No. 2, pp. 60-66).—The governmental measures for promoting cotton growing in Spain are briefly described.

Distribution of farms growing sugar cane by type of management and size for 1934-35, S. L. DESCARTES (*Puerto Rico Col. Sta. Monogr. Rpt. 3*

[1937], pp. 4).—This report is based on a special tabulation showing the number and area of farms, area planted to sugarcane, and estimated production.

Organization and returns of 130 sugar cane farms in Puerto Rico, S. L. DESCARTES and J. M. GARCÍA (*Puerto Rico Col. Sta. Mimeogr. Rpt. 4* [1937], pp. 6).—Tables show the size of farms, use of land, distribution of capital, areas in different crops, crop yields, farm receipts, cash expenses, and labor income after allowing for interest on investment.

A farm management study of 194 small tobacco farms in three municipalities of Puerto Rico, 1935–1936, J. J. SIERRALLÉS, JR., R. C. OLÓN TORRES, and F. J. JULIÁ (*Puerto Rico Col. Sta. Mimeogr. Rpt. 5* [1937], pp. 8).—Tables show average size of farms, use of land, distribution of capital, crops grown, crop yields and sales, value of livestock, receipts, expenses, and labor income, including value of privileges less interest on investment.

The importance of pig breeding for the profit capacity of agriculture in certain countries of Europe from 1927–28 to 1931–32, J. DESLARZES ([*Internatl. Rev. Agr.*], *Mo. Bul. Agr. Econ. and Sociol. [Roma]*, 26 (1935), Nos. 8, pp. 285–297; 9, pp. 317–330; 13, pp. 421–429).—The development of pig breeding in Denmark, the Netherlands (Overijssel), Switzerland, Austria, Germany, Norway, Sweden, Finland, Poland, Lithuania, Latvia, and Estonia, and the effects on returns from agriculture are discussed.

Comparative studies of the results of pig breeding in different countries, J. DESLARZES ([*Internatl. Rev. Agr.*], *Mo. Bul. Agr. Econ. and Sociol. [Roma]*, 26 (1935), No. 5, pp. 175–184).—The purpose of this article is to “investigate in the light of farm accountancy results the comparative advantages of different regions of the world in the matter of pig and pig meat production.”

Pig breeding as a factor in the earning capacity of agriculture in different countries on the eve of the crisis, J. DESLARZES ([*Internatl. Rev. Agr.*], *Mo. Bul. Agr. Econ. and Sociol. [Roma]*, 26 (1935), No. 7, pp. 241–252).—Comparisons based on the article noted above are made of the returns from pig breeding and other farm enterprises in the different countries.

Meat imports and the livestock industry in the United Kingdom, C. HUBBACK and J. K. MONTGOMERY ([*Internatl. Rev. Agr.*], *Mo. Bul. Agr. Econ. and Sociol. [Roma]*, 26 (1935), Nos. 10, pp. 353–360; 11, pp. 389–402).—The imports of meat from the British Dominions and foreign countries under the free trade policy prior to 1932 and the Ottawa and other agreements since 1932, the prices of meats, etc., are analyzed and discussed.

Production and consumption of and external trade in meat in France, P. DE VIGUERIE ([*Internatl. Rev. Agr.*], *Mo. Bul. Agr. Econ. and Sociol. [Roma]*, 27 (1936), Nos. 8, pp. 235–256; 9, pp. 275–293).—The production of livestock and meats before and after the war, the consumption, exports, and imports of livestock and meats, the regulation of imports, etc., are discussed.

Development of the production, importation, and consumption of meat in Germany, H. BÖCKER ([*Internatl. Rev. Agr.*], *Mo. Bul. Agr. Econ. and Sociol. [Roma]*, 27 (1936), No. 5, pp. 135–156).—The production of livestock of different kinds, the import duties on meats, the imports and exports of livestock and meats, and the consumption of meats are shown in tables and discussed.

Effect of changes in international price levels on the principal markets for eggs in the shell, 1926–1933, C. KAPPSTEIN ([*Internatl. Rev. Agr.*], *Mo. Bul. Agr. Econ. and Sociol. [Roma]*, 26 (1935), No. 4, pp. 133–150).—An analysis is made of the effects of differences and changes in international price levels, 1926–33, on exports and imports of eggs in shell of different countries.

Imports into the principal countries are affected by changes in international price levels, but there are no fixed relations and they vary with different

countries. The prevalence of the clearing system of trade has lost its significance to a marked degree during the last few years.

Milk transportation problems in the St. Louis milkshed, R. W. BARTLETT and W. F. CASKEY (*Illinois Sta. Bul.* 430 (1937), pp. 421-470, figs. 23).—This study is based chiefly on data in the office of the St. Louis milk market administrator and data obtained through field contacts with truckers hauling milk in the St. Louis milkshed. An analysis is made of the production of milk, types and length of hauling routes, costs of transportation, costs of operating milk trucks, etc. Ways of reducing hauling costs and other costs are discussed and recommendations made as to methods of solving some of the transportation problems of the milkshed.

In 1933-34, farmers paid approximately 17 percent of the wholesale value of the milk delivered to St. Louis for transporting it from the farm to receiving plants. About 50 percent of the milk produced for the St. Louis market is hauled directly from farms to city plants in cans. Railroad tank car shipments have not come into use. The average haul on 244 country plant routes was 20.3 miles, that on 99 main line routes 100.1, and that on short line routes, about 10 percent of the routes, 18.1 miles. Transportation rates varied from 5 to 30 ct. per 100 lb. of milk, averaging 17.7 ct. on the 244 country plant routes. Rates were not related to type of road or size of load. Low production per cow and sparse cow population increased the transportation problem materially. Rerouting to eliminate mileage and increasing size of loads would reduce costs. If seasonal fluctuations in milk production could be reduced to those of the Philadelphia milkshed, at least one truck in five could be eliminated. About 20 percent of the milk hauled to St. Louis in 1933-34 was manufactured into butter or other dairy products. Farmers could have saved about 16.3 ct. per 100 lb. on this milk if it had been marketed through country plants. Unnecessary delays in unloading at receiving plants in 1934 resulted in an average daily loss of 196 man and truck hours.

Among the recommendations are: (1) Milk now manufactured in the city should be diverted to country plants, (2) a more even seasonal production of milk should be encouraged by marketing policies, (3) hauling routes should be gradually rearranged to reduce distance and increase size of load, (4) schedules of truck arrivals at receiving stations should be revised to prevent unnecessary unloading delays, (5) a minimum pick-up charge should be established, and (6) complete records of costs of operating milk trucks should be kept by truckers.

The reorganisation of dairies in Latvia, V. KUNKIS ([*Internatl. Rev. Agr.*], *Mo. Bul. Agr. Econ. and Sociol.* [Roma], 27 (1936), No. 3, pp. 91-101).—The development of cooperative dairies and governmental regulation of dairies since the war and their effects on the industry are described.

The international organisation of the sugar market, F. ARCOLEO ([*Internatl. Rev. Agr.*], *Mo. Bul. Agr. Econ. and Sociol.* [Roma], 27 (1936), No. 6, pp. 171-186).—The international regulation of the sugar market from the signing of the Paris Convention in 1864 to the termination of the Chadbourne Agreement, September 1, 1935, is discussed.

The economic aspect of the world problem of the production and consumption of coffee, EL MARTINEZ DE BUJANDA ([*Internatl. Rev. Agr.*], *Mo. Bul. Agr. Econ. and Sociol.* [Roma], 27 (1936), Nos. 6, pp. 186-197; 7, pp. 216-232).—The production, consumption, and regulation of production in different countries are discussed. The author concludes that the great increase in the area in coffee and the resulting surpluses of coffee were due to the high prices up to 1929 resulting from the valorization artificially maintained by Brazil. The

later policy of destroying surpluses brought about equilibrium on the market and reasonable prices but cannot be continued indefinitely. "The solution probably lies in concentrating production on the better qualities."

The organisation of the international timber market, F. ARCOLEO (*[Internatl. Rev. Agr.]*, *Mo. Bul. Agr. Econ. and Sociol. [Roma]*, 27 (1936), No. 2, pp. 41-49).—The problems investigated and conclusions arrived at by the international forestry, silviculture, and timber congresses from 1900 to 1931 are briefly reviewed. The agreements made at the Conference of Timber Exporters at Berlin December 1933, Wien (Vienna) October 1934, and K benhavn (Copenhagen) November 15, 1935, are described.

International organisation of the rubber market, F. ARCOLEO (*Internatl. Rev. Agr. [Roma]*, 27 (1936), No. 11, pp. 339-356).—The position of the market previous to 1921, the first (May 1922) and second (October 1922) reports of the Stevenson committee and the Duncan report (1921) to the British Parliament, and the international agreement of 1934 are discussed.

Costs and prices: The evolution of the market for commercial fertilizers, C. KAPPSTEIN (*[Internatl. Rev. Agr.]*, *Mo. Bul. Agr. Econ. and Sociol. [Roma]*, 26 (1935), Nos. 1, pp. 1-16, fig. 1; 2, pp. 55-76).—Particular attention is given to acreages in cotton in the United States and in sugar beets in Europe, especially in Germany, and the resulting demand for nitrogenous fertilizers since the World War and the conditions, from 1923-29 to 1933-34, affecting the use of nitrogenous, phosphoric, and potassic fertilizers in Germany, Denmark, France, Great Britain, Italy, the Netherlands, Poland, Sweden, and Czechoslovakia.

The prices and consumption of commercial fertilizers, particularly nitrogenous fertilizers, were especially influenced by acreages in and prices of cotton and sugar beets. No determinable influence was exercised by wheat. Since the World War the nitrogen market has been ruled by synthetic nitrogen, especially by the German Haber-Bosch manufacture. Sulfate of ammonia, as a byproduct of gas and coke factories, has lost much of its importance, although it is almost the sole important nitrogenous fertilizer in the United States and Great Britain since the decrease in the consumption of nitrate of soda. Government intervention on the cereal market in various countries has had the effect in such countries of maintaining satisfactory price relations between the products and means of production, or of establishing new relations.

A graphic presentation of changes in the agriculture of Washington from 1930 to 1935, C. P. HEISIG (*Washington Sta. Bul.* 341 (1936), pp. 47, figs. 42).—Charts and maps show by counties the changes from 1930 to 1935 in the number and size of farms; farm population; value of farm real estate; land utilization; acreages in different crops, fruits, and vegetables; numbers of livestock of different kinds; egg production; etc.

Willamette Valley land adaptability, H. E. SELBY and L. FRYER (*Oregon Sta. Circ.* 120 (1937), pp. 4, pl. 1).—This study was made in cooperation with the U. S. D. A. Bureau of Agricultural Economics and the Resettlement Administration. The lands of the valley are classified in four valley and two hill types. The characteristics and optimum uses are briefly described for each type.

Information for prospective settlers in Alaska (*Alaska Stas. Circ.* 1, rev. (1937), pp. 36, figs. 19, map 1).—This is a revision of the circular previously noted (*E. S. R.*, 36, p. 791). It includes information as to climate, agricultural areas, schools and churches, national forests, judicial divisions, taxation, cost of living, opportunities for work and wages, transportation and communication facilities, agricultural research and extension work, freight rates, wildlife,

fisheries, reindeer production, and where settlers should locate and how they may obtain a farm.

Foreign Agriculture, [March 1937] (*U. S. Dept. Agr., Bur. Agr. Econ., Foreign Agr.*, 1 (1937), No. 3, pp. 101-154, pls. 2).—Included are articles on German Agriculture in the Four-Year Plan, by L. V. Steere (pp. 103-118), Agriculture in Palestine and the Development of Jewish Colonization, by N. W. Hazen (pp. 119-148), and Argentine Beef Subsidy—Partial Compensation for British Tariff, by P. O. Nyhus (pp. 149-151); and notes on Brazilian State [Rio Grande de Norte] Adopts Sweeping Cotton Regulations (pp. 152, 153) and Argentina Makes Plans for New Agricultural Census (pp. 153, 154).

Agricultural policy and the crisis in Poland, A. JALOWIECKI ([*Internatl. Rev. Agr.*], *Mo. Bul. Agr. Econ. and Sociol.* [Roma], 26 (1935), Nos. 4, pp. 150-161; 5, pp. 185-193).—The place of agriculture in the country, agricultural production, internal consumption of agricultural products, the economic conditions of the industry, the measures taken in regard to agricultural prices, lowering production costs, and the effect of such measures are discussed.

The development of the agrarian reform in Spain, E. MARTINEZ DE BUJANDA ([*Internatl. Rev. Agr.*], *Mo. Bul. Agr. Econ. and Sociol.* [Roma], 26 (1935), No. 7, pp. 252-263).—The effects of the law on the confiscation of the property of the nobles (August 25, 1932) and other legislation thereafter are described.

The new regulation of the wheat market in Spain, E. MARTINEZ DE BUJANDA ([*Internatl. Rev. Agr.*], *Mo. Bul. Agr. Econ. and Sociol.* [Roma], 26 (1935), No. 12, pp. 429-439).—The regulations since July 1, 1934, are outlined and their effects explained.

The wheat policy of France since 1929, H. BOKER ([*Internatl. Rev. Agr.*], *Mo. Bul. Agr. Econ. and Sociol.* [Roma], 26 (1935), No. 3, pp. 97-108).—The legislation and regulations in effect from December 1, 1929, to December 24, 1934, are discussed.

Agricultural protectionism and the agricultural situation, 1925-1929, I, II, A. EMANUEL ([*Internatl. Rev. Agr.*], *Mo. Bul. Agr. Econ. and Sociol.* [Roma], 27 (1936), Nos. 3, pp. 75-91; 4, pp. 107-122; 5, pp. 157-168).—The origins and evolution of protection from 1925 to 1929 in France, Germany, and Italy; the basic changes in agricultural production and in the consumption of agricultural products; price movements in European countries and in the United States; and the international trade in agricultural products are discussed.

Farm tenure in Iowa.—II, Facts on the farm tenure situation, R. SCHICKLE (*Iowa Sta. Bul.* 356 (1937), pp. 241-296, figs. 26).—This is the second bulletin of the series previously noted (*El. S. R.*, 76, p. 864). It is a graphic and statistical summary of the more important facts pertaining to farm tenure in the State. The text calls attention to the major relationships suggested, but no attempt has been made to interpret them.

Law on agricultural settlement in Chile, E. MARTINEZ DE BUJANDA ([*Internatl. Rev. Agr.*], *Mo. Bul. Agr. Econ. and Sociol.* [Roma], 26 (1935), No. 9, pp. 340-347).—The economic geography of the country is described, and the provisions of the agricultural settlement law of February 15, 1935, are reviewed.

Farm labor in the Yakima Valley, Washington, P. H. LANDIS and M. S. Brooks (*Washington Sta. Bul.* 343 (1936), pp. 75, figs. 29).—This study was made in cooperation with the Federal and State Works Progress Administrations and the State Department of Public Welfare. It is based on farm schedules and workers' record cards for the period July 28, 1935-July 25, 1936, for farms in two sections of each township in the irrigated area of Yakima County and on data as to family composition, age, nativity, marital status, education, mobility and occupational history, and the relief records of 468 white farm

laborers. The first part analyzes data as to seasonal employment of hired, family and exchange, and transient and resident hired labor for fruit and general crops, and hired labor for harvesting crops. Estimates are made of hired labor requirements in the Yakima Valley by weeks. Part 2 analyzes the data as to social characteristics, annual employment, income and relief experience of the laborers, and the relation of age, education, mobility, etc., to income and relief payments. Copies of the schedules and record cards are included.

The average amount of hired labor was 12 days per acre for fruit crops and approximately 2 days for general crops. The average costs per acre were fruit crops \$30, ranging from \$14.87 for prunes to \$37.04 for apples; general crops approximately \$4.50, ranging from \$1.44 for barley to \$13.61 for beets; and hops \$50 for cultivation and \$163 for harvesting. The total hired labor in 1935 was equivalent to over 1,250,000 10-hr. days. The number of hired laborers required varied from approximately 33,000 in the peak period to less than 500 in the slack period. The greatest demand was in September due to hop picking and the second highest in October due to apple picking. Wages varied from \$1.25 per day in the hop harvest to \$2.51 for apple picking. Slightly more than twice as much resident labor as transient labor was hired, transient laborers being needed chiefly for hop and apple picking.

Of the transient laborers, 38.1 percent were from Washington outside of Yakima County, 23 percent from drought-stricken States, and 18.7 percent from Oregon and California. Over 50 percent had no families, about 33 percent brought families with them, and 10 percent had families elsewhere. Transient laborers had smaller families and a smaller percentage of aged than resident families. Heads of transient families also had gone farther in school, but their children had not gone so far as residents though farther than their own parents. The farm laborers, both resident and transient, participated only to a very limited extent in community activities. As compared with the rural population of the State, an abnormally large percentage of white laborers was native-born. Housing and sanitary conditions of all laborers, and especially transients, were poor. Approximately 50 percent of the transients moved only twice a year and 28 percent only three times. Over two-thirds of the farm jobs of farm laborers lasted 1 week or less. Slightly over 75 percent of all laborers had 1 mo. of steady employment during the year, and the average total employment during the year was approximately 6 mo. Of the laborers, 47.6 percent were usually engaged in agriculture as laborers or operators. The median cash incomes were transient families \$350, resident families \$275, transient single workers \$335, and resident single workers \$215. About 20 percent of the transient single workers and 43 percent of the transient families had been on relief the preceding year. The percentage of families on relief was lowest among those having the most education. There was a low positive correlation between amount of education and income, no definite correlation between number of days employed and age, and a high positive correlation between the amount of employment and annual income.

National statistics on farmers' indebtedness: The United States census and a new Swedish inquiry, R. FREUND (*Internatl. Rev. Agr. [Roma]*, 27 (1936), No. 10, pp. 311-331).—This contribution to the problem of international statistics of agricultural indebtedness is based on a study of the reports of the 1930 Census of Agriculture and the Swedish survey of indebtedness in 1933. The data available from these general surveys are compared with each other and with those obtained by surveys made by the sample method. The methodological principles used in the surveys and the utilization and presentation of the data are discussed.

The following requirements for the elaboration and presentation of general survey data of agricultural indebtedness are formulated: "(1) For the calculation of debt ratios (debts divided by assets) the whole of the farms under review, or rather of the data supplied by these, should always be utilized; if, for example, the nonindebted farms are left out the results are no longer comparable with those of other surveys, even if those too leave out of count the nonindebted farms; (2) on the other hand, full particulars must be given for at least the debt-free farms and for those that are excessively indebted; it would also be desirable to extend this principle to all the groups of indebtedness, i. e., to establish a schematic representation of the spread of the debt ratios; [and] (3) for the tabulation and representation of the data according to size categories of farms, the basis chosen should be not that of area but that of value of land, as it is only in this way that the survey retains its definite character."

A graphic summary of farm taxation, D. JACKSON (*U. S. Dept. Agr., Misc. Pub. 262 (1937)*, pp. [2]+17, figs. 24).—This publication is one of the series previously noted (*E. S. R.*, 77, p. 117).

The retail sales tax, W. P. WALKER and E. C. WEITZELL (*Maryland Sta. Spec. Bul. 1 (1936)*, pp. 27, pl. 1).—Retail sales taxes are discussed, with particular reference to administrative problems of their collection.

The assessment and collection of motor vehicle property taxes in Maryland, W. P. WALKER (*Maryland Sta. Spec. Bul. 2 (1936)*, pp. [3]+27).—This study was made in cooperation with the Maryland State Planning Commission. The existing laws regarding the assessment and collection of motor vehicle property taxes in Maryland are described and the operation and effects discussed. Several suggested plans for improvement of legislation and administration are outlined.

[Hail insurance], F. ARCOLEO (*[Internatl. Rev. Agr.]*, *Mo. Bul. Agr. Econ. and Sociol. [Roma]*, 26 (1935), Nos. 4, pp. 161-167; 6, pp. 226-234; 7, pp. 273-282; 10, pp. 369-385; 12, pp. 439-448; 27 (1936), No. 8, pp. 256-270).—The series of articles previously noted (*E. S. R.*, 73, p. 119) is continued for the following countries: Yugoslavia (pp. 161-167), Germany (pp. 226-234, 273-282), France (pp. 369-385), Spain (pp. 439-448), and Italy (pp. 256-270).

Insurance against live stock losses in France, F. ARCOLEO (*[Internatl. Rev. Agr.]*, *Mo. Bul. Agr. Econ. and Sociol. [Roma]*, 26 (1935), No. 5, pp. 193-201).—The legislation pertaining to mutual insurance associations is reviewed. Tables show the date of foundation, headquarters, assets, extent of business, claims paid, etc., in 1933, and the assets, number of persons insured, value of stock insured, and claims paid by years, 1888-1933.

[Agricultural cooperation] (*[Internatl. Rev. Agr.]*, *Mo. Bul. Agr. Econ. and Sociol. [Roma]*, 26 (1935), Nos. 1, pp. 16-39; 2, pp. 77-92; 3, pp. 117-128; 6, pp. 205-226; 7, pp. 263-273; 9, pp. 330-339; 10, pp. 360-369; 11, pp. 402-417).—The following articles continue the series previously noted (*E. S. R.*, 73, p. 118): Austria, by M. Tcherkinsky (pp. 16-39, 77-92, 117-128); Italy, by G. Costanzo (pp. 205-219); Yugoslavia, by G. Severin (pp. 219-226, 263-273); and Sweden, by H. Lindstedt (pp. 330-339, 360-369, 402-417).

Crops and Markets, [March 1937] (*U. S. Dept. Agr., Crops and Markets*, 14 (1937), No. 3, pp. 49-68, fig. 1).—Included are the usual crop and livestock production and market reports and seasonal reports on acreage intentions for important crops, early spring lamb crop, and mohair and wool production.

Agricultural statistics for Maryland by counties, A. B. HAMILTON (*Maryland Sta. Spec. Bul. 3 (1936)*, pp. [52]).—This is a compilation from the 1935 Federal census reports and reports of the U. S. Department of Agriculture.

RURAL SOCIOLOGY

Introduction to rural sociology, C. R. HOFFER (*New York: Farrar & Rinehart, 1934, rev. ed., pp. XIV+500*).—A revised and enlarged edition (E. S. R., 64, p. 280).

Six for one and one for six (*New England Region. Planning Comm. Pub. No. 48 (1937), pp. [3]+54, [figs. 13]*).—"The purpose of this report is to outline the accomplishments and recommendations of the several State planning boards and of the New England Regional Planning Commission."

An approach to county planning, Appanoose County, [Iowa] [Ames]: Iowa State Planning Bd., 1936, pp. [10]+IX+109+[2], [pls. 77]).—"This study of Appanoose County represents an attempted appraisal of the physical and social resources of an Iowa county in the light of present maladjustments or problems. It has been compiled from various sources, and much of it is the result of original investigations and compilations by members of the Iowa State Planning Board staff. A great deal of the material herein set forth is of a sort basic to planning in any Iowa county." The two parts deal with the physical characteristics, population and employment, agriculture and industry, electrification and communication, public water supply, and transportation of the county as a whole; and the population trends, social organizations, income and employment, housing, urban land use, residential, commercial, and industrial areas, streets, and recreational facilities of cities and towns.

[Research under WPA in Virginia] (*W. P. A. Rec. Va., 1 (1937), No. 4, pp. [2]+20, figs. 21*).—Included in this periodical are the following articles: WPA Real Property Surveys Pave Way for Greater Cities, and Research Under WPA in Virginia Covers Wide Field, both by W. W. Eure; Vital Accident Statistics Rendered by WPA Traffic Surveys, by M. M. Holloway; Public Agencies to Profit by Fundamentals Governing WPA Statistical Projects, by A. W. Moore; and Rural Social Research at V. P. I. in Cooperation with WPA, by B. L. Hummel.

Southern regions of the United States, H. W. ODUM (*Chapel Hill: Univ. N. C. Press, 1936, pp. [XIV]+664, [figs. 303]*).—The objective was to present an adequate picture, partial but representative, of the southern regions of the United States in fair perspective to time-quality to geographic factors, and to the cultural equipment and behavior of the people.

Racial factors and economic forces in land tenure in the South, M. N. WORK (*Social Forces, 15 (1936), No. 2, pp. 205-215, figs. 2*).—This study is based on Federal census data for the years 1860-1930 regarding whites and Negroes in the States south of the Potomac and Ohio Rivers and west to Texas (excluding Oklahoma). An analysis is made of the intercounty migration; distribution, total and of farm operators; density of population; population centers, total and of farm operators; and of the racial factors in land ownership and tenancy in this area.

Landlord and tenant on the cotton plantation, T. J. WOOFER, JR. (*Works Prog. Admin. [U. S.], Div. Social Res., Res. Monog. 5 (1936), pp. [5]+XXXIII+288, figs. [43]*).—Large-scale cash-crop farming continues today in the areas of the Southeast that had large slaveholdings and large cotton plantations in 1860. The Negro or white tenant farmer operates most of the plantation land.

The land is adaptable to large-scale cotton production. There is a high degree of concentration of land ownership, with a consequent high proportion of tenants among the farm operators. Such areas are characterized by per capita incomes higher than those in other southern agricultural counties but lower than those in other farming sections of the Nation; small proportions

of urban and village dwellers; scarcity of nonagricultural industries; large families; poor school facilities, especially for Negroes; and a highly mobile population.

The number and proportion of large holdings in the South have decreased. The disintegration of large tracts was steady from the Civil War to about 1910, but at present there is a tendency to hold large tracts together.

Concentration on cotton increased from the Civil War until the bollweevil invasion soon after 1910. Since 1910 there has been a marked shift of the cotton acreage to the States of Texas and Oklahoma, the combined acreage in these States having increased 100 percent from 1910 to 1930, when half the cotton acreage of the United States was concentrated in those two States. Alabama, Georgia, North Carolina, and South Carolina had 5 percent less acreage in cotton in 1930 than in 1910.

Up to the inauguration of the cotton reduction program, the plantations of the South tended to be less and less self-supporting. Between 1933 and 1935 probably more crop diversification was undertaken than during any other period of the South's history. Although exclusive cotton culture results in heavy losses in bad years, the owners of large tracts still concentrate on this crop because no other use of large-scale tracts is so profitable to the landlord in good years.

Nearly half of the landlords interviewed for this study had long-term debts, mostly in the form of mortgages, averaging more than 40 percent of the appraised value of their land, buildings, animals, and machinery. These long-term debts were incurred to meet deficits or purchases of machinery, etc.

The long-term debts of tenants are usually contracted with or through the landlord and are either secured by chattel mortgage on livestock or equipment or simply carried forward on the landlord's books and added to current borrowing as a lien against future production. The tenant's short-term debts for the current season are usually incurred with the landlord, who provides the tenant's share of expenses and his subsistence advances during the crop season, charging them against future production. Sometimes the merchant makes the subsistence advances. The average time for which advances were made, as shown by this survey, was 7 mo., and the average advance was \$12.80 per family per month.

In 1934 the average net income per plantation was \$6,024. With A. A. A. benefits included, 1934 incomes compared favorably with those for 1929. On the average, the larger the plantation, the higher the gross and the net income. The average net income of the operators was \$2,572, about 10 percent of which was in the form of home-consumed products. The net income ranged from an average of \$1,340 in the Muscle Shoals area to \$7,140 in the Arkansas River area.

The landlord's net income in 1934 was sufficient to pay him 6 percent on his invested capital and about \$850 for his labor income. The average net income per family of the wage hands, croppers, share tenants, and renters on plantations in the 11 areas surveyed was only \$309, or \$73 per capita.

The average number of years lived on each farm by white plantation families in this study was 4.8 yr. and by Negro families 6.1 yr. White sharecroppers lived on each farm for an average of 4.4 yr. and Negro sharecroppers for 5.6 yr.

Southern States tax themselves for schools as much per dollar of wealth as do other sections, but the wealth is so inadequate that the resulting revenue provides a very small appropriation per child.

Displacement of tenants during the early years of the depression was an important factor in the rural relief situation. Relief grants and rehabilitation loans were necessary where the "furnishing" system ceased to operate, but these grants and loans were relatively few and of small size among plantation families and more frequent among families on smaller farming units.

Constructive efforts to improve the tenant system must take into account certain basic conditions in the South, especially those relating to the quantity and quality of the population, the interregional and international aspects of cotton economy, the type of farm organization to be promoted, and the slowness of fundamental social change.

Studies of suburbanization in Connecticut.—I, Windsor: A highly developed agricultural area, N. L. WHETTON and E. C. DEVEREUX, JR. ([*Connecticut*] *Storrs Sta. Bul.* 212 (1936), pp. 144, figs. 26).—This report is a descriptive analysis of the social adjustments taking place in a suburban area of Connecticut. It is the first in a series of studies of suburbanization and concerns the town of Windsor, situated adjacent to the city of Hartford.

Suburbanization in Windsor has been proceeding rapidly since the turn of the century. The population has more than doubled since 1910, and more than one-third of the families in the town have moved there since 1920. The movement has continued throughout the depression. At the present time, approximately half of the householders in Windsor work in Hartford, as do about 40 percent of all other gainfully employed persons. The suburban movement in this area appears to be predominantly one of "white-collar" and skilled workers seeking a country setting in which to rear their children and secure the traditional values of home life. The home-seeking pattern of the suburban movement is also reflected in the trends towards more adequate housing facilities. There was a net shift from rented to owned homes, from multiple-family dwellings to single-family residences, and from crowded conditions to a greater number of rooms per member in the household.

As reflected in the places patronized for various social and economic services and the places where organizational memberships are held, it appears that the interests of the newcomers are largely focused upon the city. The point of view of the suburbanites differs from that of the older residents, the latter being primarily interested in preserving the quiet charm of the old New England town, the former being more interested in developing Windsor into a modern suburb.

Old age assistance in Iowa, R. E. WAKELEY (*Iowa Sta. Rpt.* 1936, pt. 1, pp. 185, 186).—Data as to old age dependency are noted.

AGRICULTURAL AND HOME ECONOMICS EDUCATION

Home economics education courses (U. S. Dept. Int., Off. Ed., *Vocat. Ed. Bul.* 187 (1936), pp. VII+101, figs. 2).—This study of practices in teacher training institutions reimbursed from Federal funds for vocational education included 72 institutions in 1931 and 71 in 1935. A check list of 76 topics usually included in home economics education courses was prepared and sent to teacher trainers, State supervisors, and 1928, 1929, and 1930 graduates of the institutions who had obtained teaching positions in home economics. Two hundred returns from the first two groups represented 46 States, 68 teacher training institutions, and 47 of the 61 State supervisors and assistant supervisors. Four hundred and thirty-seven returns were received from the alumnae. The curriculum offerings in the different institutions, size of student teaching groups, facilities, standards, distribution of time to the student teaching ac-

tivities, extent of supervision of student teaching, the evaluations of topics included in courses, and the criticisms of the alumnae of the programs in their respective institutions are analyzed and conclusions and recommendations presented.

A study of the results of planning for home economics education in the Southern States as organized under the national acts for vocational education, D. C. KENT (*Columbia Univ., Teachers Col., Contrib. Ed., No. 689 (1936), pp. IX+172, figs. 21*).—This study is limited to home economics education as organized under the national acts for vocational education. Homemaking education in the white public schools of the South prior to 1918 is described. Plans for the organization and administration of home economics education in the vocational program in the southern region from 1917 to 1933 and reports of the development of home economics in vocational schools in the southern region from 1918 to 1933 are discussed. A final chapter includes a summary of the findings, the conclusions arrived at, and the recommendations made. Appendixes include a summary of reports and recommendations of committees in the Southern Regional Conferences for Home Economics in Vocational Schools, 1921-32; a summary of State conferences as described in annual reports; the personnel of State supervisory staffs in the southern region, 1917-33; and a summary of expenditures of Federal, State, and local funds for home economics in vocational schools and the number of home economics schools federally aided, by States for years ended June 30, 1918, to June 30, 1932.

4-H club work in the life of rural youth, M. E. DUTHIE (*Thesis, Univ. Wis., [Madison], pp. [9]+124, figs. 10*).—This is a thesis submitted to the University of Wisconsin in partial fulfillment for the degree of doctor of philosophy. The study was confined to Rock and Dodge Counties, Wis., Kossuth County, Iowa, and Goodhue County, Minn. Schedules were filled in by 235 4-H club members, and local 4-H club leaders and 135 former club members and 68 nonclub members from 18 to 25 yr. of age were interviewed. Data regarding rural school children from the seventh to the tenth grades were obtained in 2,619 intelligence tests, 2,372 attitude tests, and 2,619 schedules answered by the children. Notes on the methodology and copies of the schedule used are included.

Some of the findings were that education of parents had some selective effect on 4-H membership, but it is probably becoming less important; participation of parents in community organizations had some selective effect, but it was greater upon continuation of 4-H membership than on initial enrollment; integration of the family had some selective effect; the average number of brothers and sisters was 3.67 for club members and 4.12 for nonclub members; size of farm had no relation to membership and that of tenancy varied in different counties; the greater part of the 4-H club membership was in the 90-110 I. Q. groups, and the greatest selection of 4-H clubs was in the elimination of dull and superior girls and superior boys; 4-H clubs held a more important place, in point of membership, in the life of rural adolescent than any other organization, and 4-H club members were more active in other organizations than nonmembers; and the emotional satisfaction derived from membership was a significant contribution to 4-H members.

The limited data did not show that former 4-H club members have any larger income than nonmembers, but it did appear that they had more definite arrangements with parents concerning a share of the farm income. Former 4-H members showed more social participation and activity in community affairs. The more important values placed on club work by former members were: (1) "Learning to work with others", (2) "making new friends", and (3) "learning agriculture and home economics." Club members, especially

girls, had a more favorable attitude toward helping with home tasks than nonmembers. A number of questions raised in the study as to varying effects of club work on boys and girls of different ages and intelligence, type of projects, club leadership, etc., are outlined.

Marketing poultry products, E. W. BENJAMIN and H. C. PIERCE (*New York: John Wiley & Sons; London: Chapman & Hall, 1937, 3. ed., [rev. and enl.], pp. XI+401, pls. 2, figs. 212*).—This is the third edition, revised and amplified, of the text previously noted (E. S. R., 53, p. 397).

Conservation and rural life: An outline for study, A. M. BOYNTON and E. L. KIRKPATRICK ([*Madison, Wis.: Amer. Country Life Assoc., Youth Sect., 1936, pp. 29*]).—This outline for study is adapted to classroom purposes, other small discussion groups, and county, State, and regional conferences.

FOODS—HUMAN NUTRITION

[**Studies in foods and nutrition of the Iowa Station**] (*Iowa Sta. Rpt. 1936, pt. 1, pp. 77-80, 114, 115, 148-152, 153, 154*).—The work covered by these progress reports (E. S. R., 75, p. 130) includes an extension of studies by V. E. Nelson, P. M. Nelson, and B. Lowe on the effect of different fats on the destruction of vitamin A in foods, with data on the protective effect of various alleged antioxidants against this destruction (pp. 114, 115); a continuation of studies by P. M. Nelson, Lowe, and J. H. Buchanan on the relationships of the physical and chemical characteristics and constants of lard to its culinary value, with particular reference to methods of determining the plasticity of shortening agents (pp. 152, 153); new work by Lowe on methods of roasting frozen poultry for palatability tests (pp. 153, 154); a continuation of investigations by P. M. Nelson and P. P. Swanson on the causes of failure of reproduction and lactation in rats receiving dried canned pork muscle as the chief source of protein at a 15-percent level, with a study of the characteristics of the protective factor in liver, and on conditions influencing the production of uniform experimental animals in the stock colony, with data relative to the normality and uniformity of their colony and observations on dental abnormalities (pp. 148-151); a continuation of an investigation by Swanson and E. S. Haber of the association of vitamin A with plant pigments with a comparison of the vitamin A content of yellow, white (albino), and green corn seedlings (pp. 151, 152); a continuation of vitamin D studies by L. Yoder, including a comparison of the relative lengths of time required for rations unsupplemented and supplemented by vitamin D to pass through the intestinal tracts of rats and the production of antirachitic substances from various sterols (pp. 77, 78); and the completion of fluorine studies by J. A. Schulz, with a summary of the complete investigation (pp. 78-80).

New formulas for predicting basal metabolic rate from pulse rate and pulse pressure, J. M. READ and C. W. BARNETT (*Arch. Int. Med., 57 (1936), No. 3, pp. 521-532, figs. 2*).—A new method is reported for the derivation of formulas for predicting the basal metabolic rate from the pulse rate and pulse pressure. From the equation, Calories per square meter per hour = K (constant) \times pulse rate \times pulse pressure, the formulas for men and women were obtained. A table is given for use in predicting formulas to calculate the basal metabolic rate directly, allowances being made for sex and age. The accuracy of the new formulas was found to compare favorably with the accuracy of clinical calorimetry. These formulas are valuable for estimating basal metabolic rate if facilities for measuring oxygen consumption are not available and for checking the reliability of the metabolic rate, as determined by direct calorimetry. The test should be repeated when a marked disparity exists between the re-

sults obtained by the two methods. In many cases the metabolic rate predicted by the pulse rate and pulse pressure obtained in the morning before the patient arises may be more accurate than the rate determined by measuring the oxygen consumption after the patient has arisen, dressed, and traveled to the laboratory.

The basal metabolism of young men at Hyderabad (Deccan), with a study of their physical characters, S. A. RAHMAN (*Indian Jour. Med. Res.*, 24 (1936), No. 1, pp. 173-199).—The subjects were 32 healthy males averaging 22 yr. of age. Duplicate or triplicate basal metabolic determinations were made, using the Sanborn Motor-Grafic Metabolism Tester. The results show a basal metabolism 5 percent higher than in a study made in Calcutta. The pulse and respiratory rates did not differ from western standards, but the blood pressure was considerably lower and the basal metabolism 6.8 percent below the Harris-Benedict and 8.7 percent below the Aub-Du Bois standards. Physical measurements demonstrated that the weights of the subjects for height and age were below the American standards. Eight vegetarians showed an average basal metabolism about 2 percent lower than the average for the entire group. It is suggested that the humid climate may be a factor in lowering metabolism.

A diet survey of some families and institutions in Calcutta, H. E. C. WILSON, B. AHMAD, and D. N. MULLICK (*Indian Jour. Med. Res.*, 24 (1936), No. 1, pp. 161-172).—The study included 10 middle-class Bengali Hindu families, a male hostel, 2 orphanages, an Anglo-Indian school, and 2 subjects representing the poorer classes. All diets analyzed were below western standards in animal protein and fat, calcium, and phosphorus. They contained too low a percentage of dairy products and an excess of cereals. Unfortunately these deficiencies were particularly marked in the children's institutions. Assuming that the western standard cannot be readily applied to India, it would be justifiable to recommend a reduction in the quantity of cereal and increases in the proportion of atta and in the quantity of milk products consumed.

The dietitian and food allergy, C. H. EYERMANN (*Jour. Amer. Dietet. Assoc.*, 12 (1936), No. 1, pp. 1-10).—Clinically allergy appears most commonly as bronchial asthma, vasomotor rhinitis, definite types of dermatitis, urticaria, and certain gastro-intestinal disorders and cerebral manifestations. The dietitian's interest is with the clinical manifestations that are due to either the ingestion or inhalation of food substances. The dietetic management is strictly an individual matter and, therefore, ready-made dietary formulas cannot be used. The patient must be instructed to keep a dietetic diary showing not only all foodstuffs eaten and their manner of preparation but also everything else that enters the mouth, such as liquids, medicines, etc., as well as recording the symptoms in relation to the time and place of ingestion. The dietitian should know the various ways of detecting food allergy and be able to prepare a diet within narrow limitations that is nutritionally adequate, yet varied and appetizing.

A study of a dietary cause and possible elimination of early afternoon sluggishness, D. A. LAIRD, D. DELAND, H. DREXEL, and K. RIEMER (*Jour. Amer. Dietet. Assoc.*, 11 (1936), No. 5, pp. 411-421, figs. 7).—Eight healthy young men were tested on 24 consecutive weekdays to determine the cause of the first hour afternoon sluggishness among mental workers, the exact degree of lowered mental efficiency involved, and the extent to which this lowering might be prevented. On 12 days the subjects ate a noon meal of generous proportions, and on the other 12 days a lighter but satisfying dairy lunch containing a ready-to-eat cereal with top milk and a gelatin custard, or fresh fruit dessert. One-half hr. after beginning the meal each subject submitted to tests

of mental work and functions such as memory tests, speed and accuracy of mental addition, etc.

Following the dairy lunch there was an increase of approximately 6 percent in mental speed and 25 percent in mental accuracy with lessened brain anemia. In a memory test approximately 23 percent more addresses were remembered after the dairy meal than after the heavy meal. Lapses in attention were about 70 percent fewer and feelings of fatigue about 30 percent fewer after the dairy lunch than after the heavier meal. The acuity of hearing was about 35 percent greater on the dairy meal days. The experiment showed that early afternoon sluggishness is due to a marked degree to brain anemia caused by a heavy noon meal rather than to the necessity of "warming up" which has frequently been offered as an explanation. "A wise selection of light foods for the noon meal can contribute materially toward offsetting lowered mental efficiency during the early afternoon and the consequent low production of mental workers during this part of the work period."

Changes in temperature of the skin following the ingestion of food, G. BOOTH and J. M. STRANG (*Arch. Int. Med.*, 57 (1936), No. 3, pp. 533-543, figs. 3).—Observations on the blood pressure and temperature of the skin after a meal composed chiefly of meat and designed to attain satiety were made on 19 persons of normal weight and 14 obese subjects.

In both groups the blood pressure showed the same rise, both systolic and diastolic, at the start of the meal and returned to normal at the completion of the meal. In the group of normal weight subjects the temperature of the skin rose shortly after the start of the meal and continued to rise, the elevation amounting to 0.9° C. in 22 min., when eating stopped. There was a further steady increase to 1.8° in 40 min., and the maximum elevation of 2° was attained in the third 20-min. period. In the obese group the elevation of the temperature of the skin at the time of cessation of eating, 20 min. after the meal was begun, was only 0.1°. After the period of eating there was a further rise to the maximum level of 0.5° in 40 min., and during the remaining 20 min. of observation this level did not change. The elevation of the skin temperature in the obese group was definitely diminished and delayed when compared with that of the group of normal weight subjects.

The authors suggest that this difference in reaction may be one factor in the delayed sensation of satiety in obese persons and, therefore, a controlling factor in the determination of the large intake of obese persons.

The nutritional value of whole wheat and whole rice in regard to the growth, haemoglobin and calcium and inorganic phosphorus of the serum and bone of the albino rat, L. T. CHENG and H. TAO (*Sci. Soc. China, Biol. Lab. Contrib., Zool. Ser.*, 11 (1935), No. 3, pp. 97-107, fig. 1).—An investigation is described in which the nutritional values of whole wheat and whole rice in the diet of the albino rat are compared. The diet was composed of baked soybean flour 35 percent, lard 10, cod-liver oil 2, Osborne and Mendel salt mixture 1, sugar 2, and baked whole wheat or whole rice 50 percent, supplemented by green vegetables daily. The experimental period was approximately 14 weeks.

The results show that growth rate, hemoglobin content, and calcium and phosphorus contents of the serum and bone of the rats fed with whole wheat and whole rice, respectively, were approximately equal. This indicates that the nutritional value of whole rice is as good as that of whole wheat. One factor which causes the poor physical development and the deficiency diseases among the rice-eating people of South China is probably the high degree of polishing, which removes most of the vitamin B complex and mineral elements contained in the rice skin.

The use of 3-day periods in human metabolism studies: Calcium and phosphorus, S. I. PYLE and C. E. HUFF (*Jour. Nutr.*, 11 (1936), No. 6, pp. 495–509, figs. 2).—The study, with the assistance of R. Davis, was made on 10 pregnant women, aged from 22 to 34 yr., using a 3-day balance period with a 24-hr. sampling on the third day, the tests being repeated every 28 days. Food, fecal, urinary, and blood samples were analyzed for calcium and phosphorus. The results of 12 balance studies were selected to match 12 studies of the Macy group (*E. S. R.*, 63, p. 488) and 12 each from the two studies of Coons et al. (*E. S. R.*, 71, p. 880), in which longer sampling periods were used. The four sets of 12 balances were in the same period in pregnancy and were representative of approximately the same number of individuals. The selected balances did not differ significantly enough to indicate that the 3-day period fails to show an individual's metabolic tendencies. The authors feel that this method of studying calcium and phosphorus metabolism during pregnancy should be considered by the clinician.

Variability of metabolic response of different children to a given intake of calcium, H. A. HUNSCHER, F. C. HUMMEL, and I. G. MACY (*Soc. Expt. Biol. and Med. Proc.*, 35 (1936), No. 1, pp. 189–192, fig. 1).—The authors report calcium balances for from 24 to 65 consecutive days of six healthy children maintained on simple diets of from 70 to 100 calories per kilogram of body weight per day, appropriate for the age and size of the child and approximately uniform in mineral and nitrogen content, and containing 1 g of calcium per day. The children had served as subjects in previous studies. The four 5-year-old children showed an average total daily retention of calcium, ranging from 0.27 to 0.48 g and varying from 27.4 to 48.5 percent, while the values shown by two 8-year-old children ranged from 0.29 to 0.48 g and varied from 29 to 47.8 percent.

The results show the wide physiological variations present among healthy children of like age and body size and also the increments and decrements that occur in metabolism from time to time in the same individual.

The relation of the calcium content of the diet to the rate of healing of experimental fractures in rats, M. A. ROSS (*Jour. Amer. Dietet. Assoc.*, 11 (1936), No. 5, pp. 422–427).—A modified Osborne and Mendel normal rat ration, with changes in the salt mixture giving intakes of calcium varying from 0.016 to 0.545 percent and phosphorus from 0.19 to 0.5 percent, was fed to 40 male albino rats. After 35 days on the experimental diet, the left fibula was fractured and, beginning with the sixth day postoperative the animals were X-rayed every third day until healing was completed between the twenty-seventh and forty-fifth days. All the animals on the highest levels of calcium and phosphorus intakes and 12 out of 16 animals on the next two lower levels were completely healed in 27 days. The experiment was repeated on the same animals, replacing the experimental diet with the normal diet following fracture of the other fibula, and the results appear to show that previous diets low in calcium have practically no effect on the rate of healing of fractures in rats. Although there was a tendency for the fractures with a normal diet to heal a little more quickly than those with diets deficient in calcium, the experiments present insufficient evidence to justify an elaborate dietary of patients with fractures.

The question of acid and alkali forming foods, J. A. TOSBY (*Amer. Jour. Pub. Health*, 26 (1936), No. 11, pp. 1113–1116).—The author reviews scientific evidence which indicates that the question of acid- and alkali-forming foods is a negligible problem in human dietetics. The ingestion of alkali-forming foods in such amounts as a quart of milk, a quart of orange juice, or a pound

of bananas does not produce even a temporary shift in the H-ion concentration of the blood plasma or in the alkali reserve. The administration of 45 g of sodium bicarbonate is necessary to raise the H-ion concentration of the blood by even 0.2, and from 15 to 20 g of ammonium chloride are required to lower the pH by a similar amount. To accomplish the same results would require 18 lb. of oranges eaten at one time to bring about a shift toward greater alkalinity, and 4½ lb. of lean beef or 2 lb. of oysters would be necessary to produce an effect comparable to that caused by the ingestion of 15 g of ammonium chloride.

The explanation lies in the fact that the human body is a compensatory mechanism that remains stable under different conditions, maintained by the buffer action of the blood, the disposal of carbon dioxide by the lungs, and the action of the kidneys in eliminating excessive quantities of fixed acid or alkali. True acidosis occurs as a rule only in certain severe ailments in which there are disturbances of metabolic processes or organic derangements, as in nephritis and other kidney troubles, diabetes, severe diarrhea, starvation, and acute infections, such as pneumonia and sepsis. "It is obvious, therefore, that foods consumed in the usual quantities will not alter the acid-base balance of the normal person."

Effect of low levels of fluorine intake on bones and teeth, G. ELLIS and L. A. MAYNARD (*Soc. Expt. Biol. and Med. Proc.*, 35 (1936), No. 1, pp. 12-16).—Bone and teeth analyses and observations on pigment changes were made on experimental rats maintained on an adequate diet containing approximately 3 p. p. m. of fluorine and on rats receiving in addition sodium fluoride or bonemeal supplements at levels which increased the fluorine intake by from 8 to 14 p. p. m. Appropriate amounts of calcium oxide and monocalcium phosphate were added to the basal sodium fluoride diets to balance the minerals added by the bonemeal.

The results showed that a marked increase in the fluorine content of the bones after 168 days on the experimental diets was a normal increase occurring with age. Definite pigment changes in the teeth agreed with the bone analyses in showing an effect at the 8-p. p. m. level and greater effects at the higher levels of fluoride intake. Sodium fluoride and bonemeal were equally effective.

Clinical experiences in the use of determinations of blood iodine, E. P. and D. R. McCULLAGH (*Arch. Int. Med.*, 57 (1936), No. 6, pp. 1061-1066).—The following results of blood iodine determinations are reported:

In 10 patients with diseases not related to the thyroid gland, the blood iodine levels averaged 10.2 µg as compared with the normal value of 10 µg per 100 cc of blood. The level was temporarily depressed in a normal patient following violent exercise and reached 6.8 µg within 2 hr. after the exercise. In 10 patients with active hyperthyroidism, the level varied from 11.1 µg to 49.8 µg per 100 cc and in 10 patients with hypothyroidism, the average level was 7.5 µg per 100 cc of blood. In 6 cases of hypometabolism not related to the thyroid gland, 2 showed approximately normal levels and the remainder varied from 6 µg to 11.2 µg per 100 cc. In 6 cases of hypermetabolism in which there was no evidence of thyroid disease, the blood iodine levels varied from 6.1 µg to 10.3 µg per 100 cc.

The use of blood iodine values as a diagnostic aid was demonstrated in 7 cases of thyroid diseases, since under controlled conditions the blood iodine level is in most cases proportionate to thyroid activity, with a greater change in the level resulting in persons with hyperthyroidism than those with hypothyroidism. The administration of iodine raises the blood iodine level.

The selenium problem in relation to public health, M. I. SMITH, K. W. FRANKE, and B. B. WESTFALL (*Pub. Health Rpts. [U. S.], 51 (1936), No. 44, pp. 1496-1505, pl. 1*).—A survey was made of 111 rural families in South Dakota, Wyoming, and Nebraska to determine the possibility of selenium intoxication through the ingestion of locally produced selenium-bearing foodstuffs. The families resided in districts where there appeared to be a high incidence of selenium present in the soil and where cases of "alkali" disease in livestock had been reported. The study was made over a 6-week period from April to June, when home-grown foods were not being consumed generally, and thus the chief dietary constituents that might contain selenium were meats, milk and milk products, eggs, and a relatively limited amount of garden vegetables raised during the preceding year. In addition to information on dietary habits, physical examinations and urinalyses were made on representatives from 90 families.

Although many vague symptoms of ill health were found, none was sufficiently characteristic to be ascribed to the ingestion of selenium exclusively. The results of the urinalyses showed that 92 percent contained from 2 μ g to 133 μ g of selenium per 100 cc of urine. "This affords definite proof of the absorption of selenium by some of the rural population in the foregoing States. The question as to the effects of selenium, in the quantities ingested, on the health of the population remains an open one."

Experimental staphylococcus food poisoning: A study of the growth of a food poisoning staphylococcus and the production of an enterotoxigenic substance in bread and meat, F. C. KELLY and G. M. DACK (*Amer. Jour. Pub. Health, 26 (1936), No. 11, pp. 1077-1082*).—Experiments were performed to test the ability of a "food poisoning" strain of staphylococcus to penetrate and grow in the bread of peanut butter, ham, tongue, and chicken sandwiches when introduced into the fillers. In every instance after a few hours of incubation the yellow hemolytic staphylococci were recovered from portions of the bread not in contact with the fillers. Other staphylococci commonly found as contaminants of meat also penetrated into and grew in the bread. The same results were noted with the food poisoning organism when salted meat fillers were used.

Four human subjects were fed either bread or meat in which a food poisoning strain of staphylococcus had been introduced. One subject who ate bread containing millions of the staphylococci developed severe food poisoning symptoms, while the same organism grown in ham caused similar reactions in another subject. When the bread-feeding test was repeated the subject who had previously eaten the contaminated bread was not made ill, while another subject who ate the contaminated bread for the first time developed typical severe food poisoning symptoms. No symptoms were produced when another subject ate the inoculated bread. These results suggest the possibility of an individual resistance to the enterotoxigenic substance.

The enrichment of margarine with vitamins, I, II [trans. title], S. N. MATZKO (*Ztschr. Untersuch. Lebensmitl., 72 (1936), Nos. 1, pp. 76, 77; 2-3, pp. 143-148, figs. 3*).—Two papers are presented.

I. Vitamin A and D content of margarine.—The two margarine samples studied contained sunflower oil, skim milk, small amounts of egg yoke, coloring, and salt, and one sample contained cottonseed oil. The American Pharmacopoeia (1926) method of determining vitamin A was followed, using the Sherman-Burtis ration 379 (*E. S. R., 60, p. 194*). The results of therapeutic and prophylactic tests showed that when 0.8-1 g daily of the margarine

samples was added as a supplement to the basal diet or administered by pipette no vitamin A effect was observed in the experimental rats.

When 0.4–0.8 g daily of one margarine sample was fed to experimental rats receiving the Sherman-Pappenheimer ration 84 (E. S. R., 60, p. 194), the roentgenogram examinations made at the end of the 3-week period indicated that the margarine did not exert any antirachitic effect.

II. *Enrichment of margarine with vitamin A by means of carotene preparations.*—The carotene extract, which was obtained from dried carrots by extraction with petroleum ether and distillation in vacuum, was thoroughly mixed with the melted margarine and stored for 20 days in a cold dark place. The same experimental procedure for determining vitamin A, as noted above, was followed, and the basal diet was supplemented by 0.1 g daily of margarine, containing 0.05, 0.1, and 0.3 mg, respectively, of the carotene extract.

The experimental rats receiving 0.3 mg daily of the extract showed satisfactory weight gains, with no signs of xerophthalmia. While the animals receiving the 0.05- and 0.1-mg supplements, respectively, were not completely protected, the minimum therapeutic dose was assumed to be between 0.075 and 0.1 mg. One g of the carotene extract was computed to contain 10,000–13,000 international units of vitamin A, which corresponds numerically to 80–100 units in 1 g of the dried carrots, since 1 kg of carrots yielded about 8 g of extract. The tests showed that the method of preparation and the storage of the margarine containing the extract did not alter its vitamin A potency. Good results were also obtained from the use of a carotene extract prepared from dried nettles, the yield being about 4.2 g of extract from 1 kg of nettles.

The strong orange-red color produced in the margarine is due to the large amount of carotene extract necessary and, therefore, the author suggests partial substitution of carotene by a colorless vitamin A preparation such as fish oil.

The vitamin A content of three varieties of squash, M. C. SMITH (*Jour. Home Econ.*, 28 (1936), No. 7, pp. 467–469).—The Sherman-Munsell quantitative method of assay was followed, with young rats placed on experiment at 21 days of age and given weighed portions of the test food three times weekly during 8 weeks. The vitamin A-free basal ration was composed of starch 66.95 percent, extracted casein 18, Osborne and Mendel salt mixture 4, dried brewers' yeast 10, salt 1, and irradiated cholesterol 0.05 percent. The pulp of the Hubbard variety was readily eaten raw by the rats. The Zucchini and summer varieties, using the proper proportion of skin to pulp, were boiled in a very small amount of salted water until soft and translucent. One week's supply for each rat was prepared and stored in a sealed container in the refrigerator. The variations in weight and the presence or absence of the characteristic infections were taken as criteria of the amount of vitamin A in the test foods.

The results show that daily supplements of at least 0.03 g of raw Hubbard, 0.3 g of cooked Zucchini, and 0.4 g of cooked summer squash were necessary to protect the experimental animals from infection. When the results are interpreted in terms of Sherman vitamin A units, the Hubbard squash (raw) is the richest source of vitamin A and contains 50 units per gram, as compared with 5 units of the dark-green skinned Zucchini or Italian squash (cooked) and 3 units per gram of the light-green skinned summer squash (cooked). Hubbard squash may be considered a very good source of vitamin A, ranking in value with other yellow vegetables and fruits like carrots, yellow sweetpotatoes, fresh apricots, and dried yellow peaches.

The dietetic value of palm oil, T. A. BUCKLEY (*Malayan Agr. Jour.*, 24 (1936), No. 10, pp. 485-488).—The vitamin A activity of samples of palm oil, obtained from bunches of fruit in varying degrees of ripeness, was determined by colorimetric and biological methods of assay.

Judging from the growth curves of rats, the following vitamin A potencies of the oils, expressed in international units per gram, were obtained; (1) From underripe fruit 600, (2) from ripe fruit 1,900, (3) from overripe fruit (3.2 percent acidity) 1,600, and (4) from overripe fruit (15.1 percent acidity) 800 units. Colorimetric comparison of the oils with standard carotene gave different results. Expressing both sets of results as milligrams percent of carotene, the four oils should contain, by biological assay, (1) 36, (2) 114, (3) 96, and (4) 48, and by tintometric assay (1) 24, (2) 66, (3) 62, and (4) 60. The results obtained by another investigator were expressed as Carr-Price values in terms of blue Lovibond units per gram as follows: (1) 8, (2) 180, (3) 130, and (4) 185, and standard palm oil 190 blue units per gram.

The results indicate that oil from immature fruit is deficient in vitamin A. The oil as now manufactured, with an acidity of from 3 to 4 percent, appears to be the most satisfactory in dietetic value. Palm oil may be regarded as equal in vitamin A value to good average cod-liver oil, though not equal to the best, and may be recommended for culinary or medicinal use.

Vitamin A in the local treatment of wounds, S. SÁNDOR (*Lancet [London]*, 1936, II, No. 13, pp. 738-740).—Case histories are presented to show that the use of pure vitamin A oil or ointment (Vulnovitan) constitutes a real advance in the local treatment of wounds. The wound should be excised, filled with Vulnovitan, and a plaster of paris dressing applied immediately. Vulnovitan is a paraffin oil or an ointment with a vaseline body which contains 2,000 international units of vitamin A per cubic centimeter. Treatment with pure paraffin oil or vaseline failed to show the same tonic and stimulating effect on the healing that was shown by the Vulnovitan application.

The tissue response to subcutaneous injection of cod-liver oil, J. DAVSON (*Lancet [London]*, 1936, II, No. 13, pp. 737, 738, fig. 1).—The subcutaneous inoculation of sterile cod- and halibut-liver oils into the shaved ears of adult rabbits produced a marked stimulation of phagocytes, fibroblasts, and young capillaries, thus stimulating the reparative processes involved in the healing of wounds. Liquid paraffin and olive oil were relatively inert. Since the reaction to halibut-liver oil (1 in 20 dilution), which has a vitamin A content at least 100 times greater than cod-liver oil, was less than that due to whole cod-liver oil and only equal to cod-liver oil (1 in 20 dilution), the vitamin A contents of the oils are not responsible for the reaction. "It is possible that the persistent and progressive stimulation produced by cod-liver oil compared with the reaction to olive oil can be explained by the continued hydrolysis of the fats present in the cod-liver oil by tissue enzymes in the former, and by the relative absence of this process in the latter."

Crystalline torulin (as vitamin B₁) and the international vitamin B₁ standard, H. W. KINNERSLEY and R. A. PETERS (*Biochem. Jour.*, 30 (1936), No. 6, pp. 985-991).—Following the technic previously described (*El. S. R.*, 70, p. 153), the authors compared the activity of vitamin B₁ in international standard clay with crystalline vitamin B₁. The activity of the vitamin B₁, as determined by the catatorulin test, was: 2γ crystalline vitamin B₁ hydrochloride is approximately equivalent to 1 international unit of Vitamin B₁ (10 mg Jansen clay). A similar value was obtained by the formaldehyde-azo test. Good results were given by the pigeon day dose method for the crude preparation of the vitamin,

but this method did not prove satisfactory for the assay of injected crystalline vitamin B₁. The authors believe that this is probably caused by the presence in the crude preparations of factors which alter the effect of the vitamin B₁. A method is described for the quantitative extraction of the vitamin B₁ activity from acid clay so that the international standard clay extract of full activity may be injected.

Vitamin-C content of vegetables.—II, Peas, G. L. MACK and D. K. TRESSLER (*Food Res.*, 1 (1936), No. 3, pp. 231-235).—In continuation of this series (E. S. R., 76, p. 726), data are given on the relative importance of variety, maturity, size, and freshness on the ascorbic acid content of peas, as determined by the Bessey and King technic (E. S. R., 71, p. 137). The results of the chemical determinations were confirmed by biological assays of two samples, following the modified 14-day curative test as described in the previous study. The peas were grown in clay loam soil during 1935 under a single set of conditions.

Variety was found to be an important factor. Of the 17 varieties tested, the early small-seeded varieties contained more ascorbic acid than the late large-seeded varieties. The values varied from 0.4 mg for the small Mammoth Melting Sugar to 0.10 mg of ascorbic acid per gram for the large Stratagem variety. In 10 varieties the vitamin C content decreased with increasing maturity. For example, Alaska, a common variety of canning peas, contained 0.41 mg of ascorbic acid per gram when in the immature stage, 0.34 at maturity, and 0.20 mg when overmature. Determinations on the vitamin C content of different sieve sizes of 3 common varieties of canning peas showed that in a given variety the larger the peas the lower the percentage of ascorbic acid. Samples of 7 varieties were stored in the pod for 6 days at various temperatures and almost no loss of vitamin C resulted during storage at from 1° to 9° C., with considerable loss noted at from 18° to 22°.

The antiscorbutic principle in cabbage [trans. title], M. PODZIMKOVÁ-RIEGLOVÁ (*Trav. Inst. Hyg. Pub. Tchecoslov.*, 7 (1936), No. 3, pp. 106-114, pls. 3).—Following the same procedure as in previous studies (E. S. R., 72, p. 569), the vitamin C content of raw fresh cabbage and of raw and cooked saurkraut was determined. The materials were standardized against fresh lemon juice, 20 cc of which contained 20 international units of vitamin C.

The addition of 5 g daily of raw fresh cabbage to the scurvy-producing diet provided sufficient vitamin C to allow normal growth and prevent scurvy in the experimental guinea pigs. Similar results were obtained by a daily supplement of 20 g of raw saurkraut, while 5- and 10-g doses were found to be inadequate. A daily supplement of 40 g of cooked saurkraut did not prevent scurvy.

The author advocates the increased utilization of a cheap source of vitamin C, such as raw fresh cabbage, particularly during the late winter and spring seasons. When cooked fresh cabbage or raw saurkraut are consumed, the amounts eaten should be greatly increased. Cooked saurkraut cannot be considered a satisfactory source of vitamin C.

Effect of vitamin C administration on vitamin C of milk and urine of lactating mothers, F. T. CHU and C. SUNG (*Soc. Expt. Biol. and Med. Proc.*, 35 (1936), No. 1, pp. 171, 172).—This report is based upon the results of simultaneous determinations of vitamin C in the milk and urine of two lactating mothers for from 26 to 27 consecutive days, respectively. Their diet was representative of the low-class Chinese family dietaries and was adequate in caloric intake, but very low in vitamin C. In addition one received 1,000 cc of canned orange juice for 12 days and the other 2,600 mg of ascorbic acid crystals for 8 days, beginning on the fifth day of the study. A total amount of 3,500 cc of fluid was

allowed daily. The output of vitamin C in 24-hr. milk and 24-hr. urine was calculated and compared from day to day.

The storage of vitamin C in the tissues of these mothers was very low at the beginning of the experiment, for no increase in urinary excretion resulted until the large dose of vitamin C had been given for 6 days in the first case and for 3 days in the second case. When the maximum excretion, amounting to approximately 60 percent of the intake, was reached, the daily urinary output of vitamin C remained fairly constant until the vitamin supplements were discontinued, following which the excretion dropped abruptly. Following the increase or decrease of vitamin C in the diet, the vitamin C content of the milk fluctuated slowly and steadily. After the milk had reached a "saturation" level of approximately 0.03 mg per cubic centimeter, the concentration of vitamin C remained quite high for about 10 days even after the large doses of vitamin C had been discontinued.

Pharmacologic and therapeutic properties of crystalline vitamin C (cevitamic acid), with special reference to its effects on the capillary fragility, I. S. WRIGHT and A. LILIENFELD (*Arch. Int. Med.*, 57 (1936), No. 2, pp. 241-274, figs. 7).—Following a detailed review of the properties and the laboratory and clinical findings on cevitamic acid, the authors present case histories and summarize their experiences with the clinical use of crystalline vitamin C. The first series of cases is grouped under the heading of vitamin C deficiency, and the 20 patients with marked scurvy were promptly cured by the addition of crystalline vitamin C to the scurvy-producing diets. Three patients with purpura and 3 patients with true hereditary hemophilia showed doubtful results after the administration of crystalline vitamin C. A standardized modification of the tourniquet test for capillary fragility, which has been found very useful in the study of these cases, is presented.

Cevitamic acid is indicated for patients and infants who are unable to take citrus fruit juices, for cases of gastric or duodenal ulcer, and for severe ulcerative colitis. Patients who are unable to utilize vitamin C, even though the intake is adequate, may be successfully treated with cevitamic acid administered parenterally. Although the minimum dose of cevitamic acid required as a preventive has not been definitely established, the vitamin should be added to all diets poor in vitamin C to bring the content up to the 20- to 30-mg level.

As criteria of "subclinical" scurvy, the authors used the history of a diet poor in vitamin C taken over a protracted period of time, a definite increase in capillary fragility on several checked tests, and a response by a decrease in capillary fragility to within the normal range (0-10) on exactly the same regimen with the single addition of cevitamic acid.

Effect of crystalline vitamin C (ascorbic acid) on tolerance to tuberculin, M. M. STEINBACH and S. J. KLEIN (*Soc. Expt. Biol. and Med. Proc.*, 35 (1936), No. 1, pp. 151-154).—When tuberculous guinea pigs receiving a normal diet which included an abundance of fresh lettuce as a source of vitamin C were subjected to daily injections of crystalline vitamin C, an increased tolerance to repeated large doses of tuberculin was established. The results suggest that vitamin C may be of value in tuberculosis by combating the prolonged toxemia of the disease.

Studies on reduced ascorbic acid content of the blood plasma, L. D. GREENBERG, J. F. RINEHART, and N. M. PHATAK (*Soc. Expt. Biol. and Med. Proc.*, 35 (1936), No. 1, pp. 135-139, figs. 2).—The plasma ascorbic acid levels of seven normal adults were determined before and after the ingestion of 6 oz. of orange juice by deproteinizing the blood plasma with tungstic acid and titrating with

2,6-dichlorophenolindophenol according to the method of Farmer and Abt (E. S. R., 74, p. 135).

An appreciable rise of the ascorbic acid level of the plasma ranging from 15 to 69 percent was found from 2 to 4½ hr. after the administration of this relatively small dose of vitamin C. In four individuals receiving 0.5 g of ascorbic acid per 100 lb. of body weight, the ascorbic acid content of the plasma reached the peak from 2 to 4 hr. after ingestion. Determination of the postabsorptive plasma vitamin C concentration was made on 55 medical students. The average level was 0.72 mg percent, with 45 percent of the group showing values below 0.7 mg percent. A close parallelism was found between the plasma ascorbic acid values and the urinary excretion following test doses of from 250 to 300 mg of vitamin C. Experiments on three monkeys previously maintained on a suboptimal intake confirmed this finding.

The authors believe that fasting plasma ascorbic acid levels below 0.7 mg percent are probably suboptimal, levels ranging from 0.7 to 0.9 mg percent appear to be adequate, and optimal levels probably lie above this range. Reduced ascorbic acid plasma levels below 0.5 mg percent should be considered low. For satisfactory comparative data, determinations should be made on fasting blood specimens.

Reduced ascorbic acid content of blood plasma in rheumatoid arthritis, J. F. RINEHART, L. D. GREENBERG, and F. BAKER (*Soc. Expt. Biol. and Med. Proc.*, 35 (1936), No. 2, pp. 347-350, figs. 2).—In this preliminary report plasma ascorbic acid levels determined by the method of Farmer and Abt (E. S. R., 75, p. 588) are reported graphically for 36 cases of rheumatoid arthritis, 12 of which composed a control group in that they had been maintained for a period of months on a high vitamin C intake. The plasma ascorbic acid levels of this group ranged from 0.9 to 1.39 mg, with an average of 1.1 mg per 100 cc. The values for a second group of 21 cases ranged from 0.14 to 0.66 mg per 100 cc. This group included 5 for whom a high vitamin C intake had been prescribed but not followed systematically, and 3 others who had taken a good but not a high vitamin C supply for months. The latter were thought to have some fault in absorption or utilization, for in the majority of the other cases in the group the reduced ascorbic acid levels rose promptly following intensive vitamin C therapy. A final group of 3 cases of old inactive rheumatoid arthritis gave reduced ascorbic acid plasma levels of 0.59, 0.79, and 1.56 mg per 100 cc.

These results indicate that the blood plasma ascorbic acid (reduced form) in active cases of rheumatoid arthritis is regularly low if the individuals have not been maintained on a high vitamin C supplement, and suggest that in some cases the intake required to maintain adequate vitamin C levels in the plasma is much above the average requirement for normal individuals. The evidence supports the earlier theory (E. S. R., 71, p. 428) that vitamin C deficiency may operate as a contributory factor in the etiology of some cases of rheumatoid arthritis.

The effect of the administration of sodium bicarbonate and of ammonium chloride on the amount of ascorbic acid found in the urine, E. E. HAWLEY, J. P. FRAZER, L. L. BUTTON, and D. J. STEPHENS (*Jour. Nutr.*, 12 (1936), No. 2, pp. 215-222, figs. 2).—Essentially noted from another source (E. S. R., 76, p. 567).

Cereals and rickets, VI, VII (*Biochem. Jour.*, 30 (1936), Nos. 2, pp. 177-188; 7, pp. 1126-1134).—In continuation of this series of studies at the Wisconsin Experiment Station (E. S. R., 72, p. 571), two papers are presented.

VI. The comparative rickets-producing properties of different cereals, B. H. Thomas and H. Steenbock.—The authors report experiments on rats fed a

low calcium diet. Rolled oats, patent flour, whole wheat, polished rice, and yellow corn were compared in their capacity to produce rickets when they comprised 75 percent of the low calcium ration. When judged by bone analysis and the line test, these cereals were found to be very similar in their rickets-producing properties.

VII. *The role of inorganic phosphorus in calcification on cereal diets*, J. T. Lowe and H. Steenbock.—The experiments of Templin and Steenbock were repeated to determine the organic-inorganic phosphorus relations of germinated autolyzed corn, immature corn, and hydrochloric acid-treated corn when they replaced part of the cereal content of the Steenbock-Black rickets-producing ration 2965. The results are summarized as follows:

The germinated autolyzed corn was superior in antirachitic effect to mature and germinated corn, with evidence of an inverse relationship between the phytin-phosphorus content and antirachitic effectiveness. There was a progressive improvement in calcification when the calcium:phosphorus ratio of the diet was increased from 1:1 to 2.1:1, running parallel with the rise in phosphorus content. Phytin was not found to be a significant source of phosphorus while sodium glycerophosphate proved superior to phosphoric acid as a phosphorus supplement to improved calcification. Immature corn was definitely less rachitogenic than mature corn, and this difference was correlated with a simultaneous rise in inorganic phosphorus. Immature corn and immature autolyzed corn, both containing the same amounts of inorganic phosphorus, showed comparative antirachitogenic effectiveness. The increase in inorganic phosphorus could be almost entirely accounted for by hydrolysis of phytin. A slight superiority in calcification occurred when hydrochloric acid-treated corn was included in the ration. The possible existence of other factors must be considered, since the increase in inorganic phosphorus content was not the only factor in improving calcification.

TEXTILES AND CLOTHING

Durability and resistance to water of certain umbrella fabrics, V. SYKES and K. CRANOR (*Amer. Dyestuff Rptr.*, 24 (1935), No. 26, pp. 725-729, figs. 4).—The umbrella fabrics tested were three plain weave silks, two plain weave silk and cotton mixtures, two twill weave cottons, one plain weave cotton, and one plain weave rayon. Chemical and physical tests were made to determine the number of yarns per inch, yarn twist, thickness of the fabric, diameter of the yarn, breaking strength, elongation, and folding endurance. Tests for waterproofing, the resistance of the fabric to breaking, and the fastness to light were estimated. Following a 2-mo. exposure to the weather, the samples were retested.

The highest breaking strength, warp folding endurance, and resistance to water were shown by the unweathered cotton fabrics. Cotton also showed the greatest resistance to folding endurance and edge breaking after weathering. The silk and rayon fabrics tested were less durable and were the lowest in water resistance. The deterioration of the silk fabrics during the weathering period prevented further tests. All of the weathered fabrics were low in resistance and lost color after the exposure to the weather for 1,501 hr. in midsummer. The data indicate that the most important factors influencing water resistance are closeness of weave, thickness of the fabric, diameter of the yarn, and the yarn twist.

Formaldehyde as a protective agent for wool, F. BARR and R. EDGAR (*Textile Res.*, 7 (1937), No. 4, pp. 175-179, figs. 2; abs. in *Iowa Sta. Rpt.* 1936, pt.

1, pp. 157, 158).—Tests similar to those previously conducted at the Iowa Experiment Station (E. S. R., 76, p. 140) on untreated wool were made on formaldehyde-wool.

Treatment with formaldehyde resulted in a 36 percent less loss in wet strength after subjection for 1 hr. at 100° C. to 0.25 N hydrochloric acid, and of a 25 percent less loss when 0.5 N acid was used. The formaldehyde-wool lost the same weight, 17 percent more sulfur, and 4 percent less nitrogen than the untreated wool in 0.75 N acid. In 6 N acid for 10 hr. at 10° the formaldehyde-wool showed less percentage weight, nitrogen, and wet strength losses, and a greater total sulfur loss. After 10 hr. of treatment in dilute sodium hydroxide at 40°, the residues were nearly constant in total nitrogen and non-sulfate sulfur, with less weight loss in the formaldehyde-wool, which had a measurable wet strength at 0.2 N alkali, a concentration approximately four times that beyond which the untreated wool failed. In concentrated alkali the percentage losses of non-sulfate sulfur, weight, and wet strength were the same for both wools, with the total nitrogen content of the formaldehyde-wool remaining unchanged while that of the untreated wool increased.

"Virgin wool" bats and wool-filled comforters in California, J. F. WILSON (*Natl. Wool Grower*, 27 (1937), No. 1, pp. 18–20, figs. 2).—The recently amended regulations administered by the Department of Professional and Vocational Standards of California regarding tags giving the definitions of virgin wool, blended wools, wool waste, and wool shoddy to be attached by the manufacturer to bedding and upholstery materials sold in California are outlined. The wool shoddy label must be red and the other three white. It is pointed out that these regulations fail to provide any guarantee that the article will have a high insulation value or give any information regarding the length of the fiber. A summary of data obtained from testing a comforter filling labeled "100 percent virgin wool" and another wool bat made from recorded white worsted thread waste illustrates that the label virgin wool may not be an indication of a good article.

Oxidative degradation of silk, R. L. JOHNSON, E. C. WALDE, and R. EDGAR (*Iowa State Col. Jour. Sci.*, 11 (1936), No. 1, pp. 5–14, fig. 1).—In this study, conducted at the Iowa Experiment Station, the authors present quantitative data of the effect of hydrogen peroxide and aqueous potassium permanganate in 10 hr. at 40° C. on the weight, nitrogen, ash, and wet strength of wild silk fibroin, silk fibroin, and black iron-weighted, white lead-weighted, tin-weighted, tin- and lead-weighted and zinc-weighted silks of typical commercial quality.

The rapid loss of strength shown by the weighted silks treated with the permanganate was similar to that which occurred in dry cleaning and laundering lead-weighted and tin- and lead-weighted silks, as previously reported (E. S. R., 73, p. 573). The weighted silks were not changed in wet strengths by high concentrations of hydrogen peroxide, and the degree of degradation was less than by the permanganate. It has been shown that "nitrogen of wild silk fibroin is a decreasing linear function of the volume of potassium permanganate at a given concentration, that nitrogen of silk fibroin and nitrogen of wild fibroin are almost linear functions of the concentration of oxidant, that dilution of fibroin by weighting results in greater solution of its nitrogen upon oxidative degradation, and that loss and rate of loss in wet strength with increasing concentration of permanganate, different for the various fabrics, are greater than loss and rate of loss of fibroin."

Degradation of five weighted silk fibroins by steam, R. L. JOHNSON and R. EDGAR (*Iowa State Col. Jour. Sci.*, 11 (1936), No. 1, pp. 15–20, figs. 2; *abs. in Iowa Sta. Rpt. 1936, pt. 1, pp. 155–157*).—In continuation of previous studies

(E. S. R., 76, p. 140), the effect of subjecting weighted and unweighted plain woven silk fabrics to the action of steam for 1 hr. at from 0 to 38 lb. pressure and for from 1 to 5 hr. at 8 lb. pressure was investigated. Chemical analyses and tests to determine the wet strength of the residual fabrics were made.

The following percentage conversions of the fibroin to soluble forms of nitrogen in 1 hr. at 38 lb. pressure were observed: Lead-weighted 43.9, zinc-weighted 38.6, tin-weighted 35. tin- and lead-weighted 15.4, iron-weighted 10.9, and unweighted silk fibroin 4.5, and in 5 hr. at 8 lb. pressure the values observed were 38.3, 34.3, 19.3, 12.6, 10.4, and 2.3, respectively. The greatest conversion of fibroin was noted at pressures between 18 and 28 lb., with the exception of the tin-weighted silk which lost most between 28 and 38 lb., while at 8 lb. pressure the greatest loss took place in the 2- to 3-hr. steaming period except for the lead-weighted silk which lost most during the 4- to 5-hr. period. The silk fibroin and the tin-weighted silk withstood steam at a pressure of 18 lb. for 1 hr., and the tin-weighted, lead-weighted, and zinc-weighted silks showed no measurable wet strength after 1 hr. at 38 lb. pressure. A pressure of 38 lb. was required to cause browning of the silk fibroin, while the weighted silks became brown after 1 hr. of steaming at 8 lb. pressure. In 1 hr. at 38 lb. the zinc-weighted silk lost the most weight, 14.2 percent, and the tin-weighted silk showed the maximum decrease in the percentage of ash, 6.3. It would appear that the dilution of fibroin by wetting increased the conversion to soluble derivatives by steam, and that the loss in wet strength with increasing time or temperature was greater than the loss of fibroin.

HOME MANAGEMENT AND EQUIPMENT

The rural homemaker in southern Rhode Island as a paid worker, M. WHITTEMORE and B. M. KUSCHKE (*Rhode Island Sta. Bul.* 259 (1936), pp. 32, fig. 1).—A survey was made of 624 rural women, or about one-fifth of the total number of married and unmarried women and girls of Washington County who were listed by the 1930 census as gainfully employed.

While most women gave more than one reason for working outside the home, approximately 85 percent listed necessity as the main reason and 33 percent worked to obtain "luxuries" such as electrical equipment and washing machines. To 7.7 percent it served as an outlet for surplus energy, 4.2 percent worked for financial independence, 1.8 percent to escape housework, and 10.4 percent to pay for the home, help relatives, educate children, or for other miscellaneous reasons. The following types of work were engaged in: Industrial, 1.1 percent. The average amount of money earned by 333 of the women was \$17.79 per week.

A survey of the equipment in the homes showed that a large proportion had electricity and some were very completely supplied with modern equipment. About 60 percent of the income-earning homemakers bought at least three-fourths of the clothing for their families and about one-half bought all of the bread consumed, while one-third sent out part or all of their laundry and nearly 9 out of every 10 women bought canned foods.

"A few women felt that it was a hardship to have to carry on income-producing work in addition to that of the home, and a few others reported that their husbands did not like to have them do so. In most cases, however, both the worker and the family seemed not only willing but anxious that her work should continue."

Economics of the household: Its administration and finance, B. B. ANDREWS (*New York: Macmillan Co., 1935, rev. ed., pp. IX+626*).—This revised

edition of the text previously noted (E. S. R., 50, p. 797) "has been largely rewritten and enlarged at a number of points. The concept of management taken as the foundation principle of economic analysis has been extended, in a partial way at least, to the whole range of family household functions and interests." Chapters have been added on personality economics and bioeconomics of the family; business economics and social economics of the household; money income and the household; household budget studies; household credit and debt; family health, sickness, and death costs; and household buying and handling household resources.

[Studies in household equipment by the Iowa Station] (*Iowa Sta. Rpt. 1936, pt. 1, pp. 153, 154, 155, 156, figs. 4*).—This progress report (E. S. R., 75, p. 140) contains summaries of a continuation by L. J. Peet of studies on the application of heat from electric surface units to cooking utensils of different materials and finishes, and of tests by Peet and B. Lowe to determine the feasibility of baking cakes, rolls, biscuits, and cream puffs from a cold start in gas, electric, and kerosene ranges.

List of inspected household electrical appliances (*Underwriters' Labs. List HEA 736 [1936], pp. 103, pl. 1*).—This list contains household electrical appliances, small wiring devices, and other similar equipment.

MISCELLANEOUS

Annual report of the director [of Delaware Station] for the fiscal year ending June 30, 1936, C. A. McCUE ET AL. (*Delaware Sta. Bul. 205 (1936), pp. 46, figs. 2*).—The experimental work not previously referred to is for the most part noted elsewhere in this issue.

Report on agricultural research [of Iowa Station] for the year ending June 30, 1936, I, II, R. H. BUCHANAN ET AL. (*Iowa Sta. Rpt. 1936, pts. 1, pp. 220, figs. 25; 2, pp. 72, figs. 13*).—Part 1 of this report includes reports on all active projects except those relating to corn; part 2, a report on all work coordinated under the Iowa Corn Research Institute. The experimental work not previously noted is for the most part referred to elsewhere in this issue.

Forty-seventh Annual Report [of New Mexico Station, 1936], F. GARCIA (*New Mexico Sta. Rpt. 1936, pp. 70, figs. 2*).—The experimental work not previously referred to is for the most part noted elsewhere in this issue.

Farm Research, April 1, 1937 (*Farm Res. [New York State Sta.], 3 (1937), No. 3, pp. 16, figs. 11*).—In addition to several articles abstracted elsewhere in this issue, there are included Much Seed Research May Be Done on the Farm, by M. T. Munn (p. 2); New Crops for Old Lands, by U. P. Hedrick (pp. 4, 9); The Rock Alpines (p. 8); and Pear Midge Control, by F. G. Munding (p. 9).

Results of field crop, shelterbelt, and orchard investigations at the United States Dry Land Field Station, Ardmore, S. Dak., 1911-32, O. R. MATHEWS and V. I. CLARK (*U. S. Dept. Agr. Circ. 421 (1937), pp. 48*).—The experimental work not previously referred to (E. S. R., 58, p. 396) is for the most part noted elsewhere in this issue.

Bibliography of tropical agriculture, 1934, 1935 (*Roma: Internatl. Inst. Agr., 1935, pp. VII+247; 1936, pp. VII+256*).—Continuing the series (E. S. R., 72, p. 142), these classified bibliographies deal with the years 1934 and 1935, respectively. Annotations in English and French are given.

NOTES

Delaware University and Station.—Dr. J. F. Adams, associate professor of plant pathology and soil bacteriology and associate plant pathologist and soil bacteriologist, has resigned to engage in commercial work on August 1.

Florida University.—A 10-story building, originally designed for a hotel and located somewhat nearer the main part of Gainesville than the campus, has been acquired by the university through the use of State and private funds, and its construction has been practically completed. It will house the State museum, the general extension division of the university, the State plant board, radio studios, and some other departments.

Indiana Station.—Dr. R. M. Caldwell of the U. S. D. A. Bureau of Plant Industry has been appointed chief of the department of botany, and Dr. R. W. Samson assistant chief.

Iowa College and Station.—Dr. A. G. Norman, biochemist at the Rothamsted Experimental Station, has been appointed professor of soil bacteriology and soil bacteriologist beginning in September. Dr. Walther Kubiens, professor of agronomy in the Hochschule für Bodenkultur of Wien (Vienna), is serving as guest professor of soils for 6 months, giving instruction in his new method for the microscopic examination of soils and studying the application of this micropedological technic to the genetics of soils, the microflora, and the characteristics of soils which affect erosion.

Kansas College.—Honorary degrees of doctor of science were conferred at the recent commencement on Dr. Flora Rose, director of the College of Home Economics of Cornell University, and F. C. Sears, professor emeritus of horticulture at the Massachusetts College.

Louisiana University and Station.—Dr. William Carver Schofield of the Maryland Livestock Service Laboratory has been appointed instructor in veterinary medicine and assistant veterinarian, dividing his time equally between teaching and the investigation of poultry diseases.

Maine Station.—*Science* notes the retirement in June of Dr. Edith M. Patch, entomologist since 1904.

Massachusetts College.—The honorary degree of doctor of science was conferred at the recent commencement on Dr. Charles S. Plumb, '82, emeritus professor of animal husbandry in Ohio State University.

Missouri University and Station.—At the recent commencement the LL. D. degree was conferred on Dean and Director C. B. Hutchison of the California University and Station.

Exercises honoring Dr. J. W. Connaway, associated with the institution for 49 years, mainly as professor of veterinary science and veterinarian, were held June 22.

The registered saddle stallion, Dysart McDonald No. 12162, bred and raised at the station, has been sold to the Dominican Republic for use in the improvement of saddle stock.

New York State Station.—The retirement is announced of Director U. P. Hedrick, to be effective on January 15, 1938. Clinton Stimson has been appointed to a new fellowship providing for studies on changes in vitamin potency in fruits and vegetables during their preparation for freezing.

Cornell University and Station.—Ground has been broken for a new building for the New York State Veterinary College to be named in honor of the late Dean Veranus A. Moore. It is expected that this building will be completed about May 1, 1938, at a cost of about \$300,000. It is a 3-story structure, L-shaped, with a 117-ft. frontage and 170-ft. depth, and is faced with native stone to harmonize with the newer buildings of the university.

An experimental aviary has been built on the top of Fernow Hall, which houses the department of ornithology. This aviary, a metal encased structure, will have large wire cages, containing smaller shelters to protect the birds, and a hall the length of the aviary where bird experts may experiment, store food and equipment for the birds, and record results. Another use of the aviary will be to study bird migration. Birds will be confined therein during periods of the year when they normally migrate to discover how long this desire to migrate persists and how it relates to physical changes in the birds.

Dr. T. Lyttleton Lyon, for 31 years professor of soil technology and head of the department of agronomy since 1911, retired on July 1. He was succeeded by Dr. Richard Bradfield, professor of soils in Ohio State University and associate agronomist in the Ohio Station.

North Dakota Station.—Dr. Perry F. Trowbridge, director from 1918 to 1934 and widely known for his contributions to meat investigations, died May 15 at the age of 71 years. A native of Michigan and a graduate of its State normal school and university, Dr. Trowbridge received the Ph. D. degree in 1906 from the University of Illinois, where he had become assistant professor of chemistry. From 1907 to 1918 he was assistant professor and professor of agricultural chemistry in the University of Missouri. In 1918 he also served as president of the Association of Official Agricultural Chemists.

Pennsylvania College and Station.—The Regional Laboratory for Pasture Research (E. S. R., 75, p. 3) was dedicated May 4. Addresses descriptive of the policy and program of the laboratory were made by Dr. J. T. Jardine, Director of Research and Chief of the Office of Experiment Stations, U. S. Department of Agriculture; P. V. Cardon, head of the Division of Forage Crops and Diseases, U. S. D. A. Bureau of Plant Industry; and Dr. R. J. Garber, director of the laboratory. A conference followed of directors of all State experiment stations in the 12 Northeastern States regarding cooperative relations, and a plan was agreed to whereby each station will be represented on the advisory council by a member who will be appointed a collaborator by the U. S. Department of Agriculture.

The laboratory and attached greenhouses have been built at a cost of about \$100,000. The college has also made available about 30 acres of land for field experiments. A staff of six specialists began operations on July 1.

Vermont University and Station.—A Golden Anniversary Reunion dinner and reception were held under the auspices of the Agricultural College Alumni Association on June 12 in honor of Dean and Director J. L. Hills, thereby giving recognition to his 50 years of service, which began on March 12, 1888.

Virginia Station.—A prize of \$50 has been awarded by the State Academy of Science to R. G. Henderson, assistant plant pathologist, for a paper entitled Studies on the Downy Mildew of Tobacco.

Wisconsin University.—Warren W. Clark has been appointed associate director of agricultural extension.

EXPERIMENT STATION RECORD

VOL. 77

SEPTEMBER 1937

No. 3

THE DEPARTMENT OF AGRICULTURE APPROPRIATION ACT, 1938

Appropriations carried in the act for the support of the Federal Department of Agriculture for the fiscal year ending June 30, 1938, signed by the President on June 29, 1937, aggregate \$802,245,208. This is greatly in excess of the provisions in corresponding acts for previous years, but this is mainly because for the first time the expenditures of the Agricultural Adjustment Administration are included. The authorization for this agency is \$500,000,000, and \$180,000,000 additional is for roads. Other major allotments are \$24,390,780 for the Soil Conservation Service, \$18,892,182 for the Forest Service, \$15,864,000 for the cattle disease elimination campaign, \$13,690,672 for extension work, \$10,373,098 for the Bureau of Animal Industry, \$6,212,698 for the Bureau of Agricultural Economics, and \$6,120,000 for payments to the States for experimentation under the Hatch Act and supplementary legislation.

Comparable appropriations for the previous year totaled \$666,916,606. The difference, a resultant of various increases and decreases, is thus \$135,328,602. Of this amount \$112,000,000 represents enlarged provision for roads activities, and there is an increase of \$30,000,000 for the AAA.

No detailed estimate is available at the time of writing as to the funds available for research, but existing projects are for the most part continued, in some cases with increased allotments, and there are a number of new undertakings. Provision was duly made for the full amount of the special research fund authorized for the Department under the Bankhead-Jones Act of 1935, so that for this purpose \$1,200,000, an increase of \$400,000, will be available.

The Bankhead-Jones funds for the State experiment stations are further enlarged by \$600,000, as authorized by the act, making \$1,800,000 available to them plus the usual \$720,000 under the Hatch Act, a like amount under the Adams Act, and \$2,880,000 from the Purnell Act. In addition there are supplementary payments of \$52,066 for work in Hawaii, \$22,500 in Alaska, and \$107,245 in Puerto Rico. These represent an increase of \$7,500 for Alaska but a

net decrease of \$10,000 for Hawaii. The allotment for Puerto Rico will again be divided between the Territorial and Federal stations, the former receiving \$40,000 for research on problems of local concern and the latter \$67,245 for development as a tropical outpost station of the Department.

For the expenses of the Office of Experiment Stations itself, \$161,735 (plus \$24,000 from Bankhead-Jones funds) will be available for the administration of the various experiment station acts, the publication of *Experiment Station Record*, and related purposes. This is an increase of \$8,000 over the previous year, as authorized under the Bankhead-Jones legislation.

The funds administered by the Extension Service are increased from \$13,330,672 to \$13,690,672. The full authorized increase of \$1,000,000 in Bankhead-Jones funds is provided, but \$645,000 has been deducted from certain other supplementary funds hitherto available under a sliding scale arrangement designed to effect their complete replacement by Bankhead-Jones funds by 1940.

The Weather Bureau is allotted \$4,703,049, an increase of \$830,025. Of this amount, \$696,090 is for additional aerological work, mainly commercial airway meteorological service, and including \$140,000 for this purpose transferred from funds hitherto appropriated to the U. S. Department of Commerce.

An increase from \$10,063,963 to \$10,373,098 is indicated for the Bureau of Animal Industry. The principal item of increase is \$174,806 for the Federal meat inspection, making the total for this purpose \$5,433,000. There is also \$103,000 additional for the tuberculosis eradication work of the Bureau, for which \$1,603,000 will be available. Of this amount, \$199,884 is for the payment of indemnities, and this is supplemented elsewhere in the act by authorizations of the use of \$15,894,000 carried in special legislation for the elimination of diseased dairy and beef cattle. A new item is a provision of \$10,000 for the study of periodical ophthalmia, or "moon blindness", in horses and mules.

Comparatively few changes are made in the allotments for the Bureau of Plant Industry, but its total rises from \$4,551,206 to \$4,833,048. Among the new expenditures authorized are \$100,000 for the construction of a sugarcane laboratory at Houma, La., to replace a structure destroyed by fire, \$15,000 for a wheat laboratory at Manhattan, Kans., \$87,693 for additional land and increased maintenance costs at the National Arboretum, and \$29,000 for the development of improved deciduous fruits and vegetables.

A total of \$18,892,182 is provided for the Forest Service. Entering into its \$1,153,677 net increase over the previous act are \$500,000 additional for the acquisition of land for national forests, \$610,000 additional for National Forest administration, and \$171,409 for forest research.

The funds provided for the Bureau of Entomology and Plant Quarantine show a net increase from \$5,567,675 to \$5,711,398. This is apportioned among a large number of projects, such as \$75,000 additional for Japanese beetle control, a like amount to begin a campaign against the sweetpotato weevil, \$39,972 additional for phony peach and peach mosaic eradication, \$79,475 additional to combat insect pests of forests and ornamentals, \$50,000 additional for white pine blister rust control, \$199,704 additional for Dutch elm disease eradication, \$19,961 to extend scouting operations for the pink bollworm, \$24,992 for an extension of the insect pest survey, \$51,044 additional for the foreign plant quarantine, and \$10,000 additional for an investigation of tick infestation around the island of Martha's Vineyard, Mass. On the other hand, there is a reduction in the funds available for screwworm control from \$460,000 to \$75,000 (plus \$22,452 additional for studies of more effective methods of control).

There is an increase from \$1,961,224 to \$2,127,840 for the Bureau of Biological Survey, the largest addition being one of \$114,228 for the maintenance of additional game ranges and bird refuge areas. An increase of \$33,000 for biological investigations is provided for expanding studies in forest wildlife relationships and the establishment of additional wildlife research stations, as well as increases of \$9,888 for reopening the Blackwater, Md., Experiment Station for studies in the production of muskrats and other fur animals, and one of \$7,500 for further cooperation with other public agencies in food habits investigations.

The allotments for the Bureau of Agricultural Economics show a total of \$6,212,698 and a net increase of \$219,802. Of this amount \$72,496 is for additional studies in farm management and practice and the marketing and distributing of farm products, \$24,943 for additional statistics (including \$10,000 for peanuts under an act of June 24, 1936), and \$99,015 more for the enforcement of various inspection measures.

Increases from \$219,085 to \$245,085 are authorized for the Bureau of Home Economics. These will permit of increased research on wool utilization and other projects and provide for an expansion of the home economics information service.

The Commodity Exchange Act of June 15, 1936, replaced the Grain Futures Act of 1922, extending the jurisdiction of the Department to futures trading and exchange practices affecting cotton, millfeed, butter, eggs, potatoes, and rice. A total of \$500,000, an increase from \$296,500, is made available to the newly established Commodity Exchange Administration for the enforcement of the act.

One of the major increases is allotted to the Bureau of Public Roads, the total for this Bureau rising from \$60,000,000 to \$167,-

500,000. Of this amount, \$155,000,000 is for Federal aid highway construction, \$10,000,000 for the elimination of grade crossings, and \$2,500,000 for public lands highways. There is also an increase from \$8,000,000 to \$12,500,000 in the appropriations for the construction of forest roads and trails.

A decrease from \$24,869,265 to \$24,390,780 is noted in the aggregate for the Soil Conservation Service, mainly in its allotment for soil and moisture conservation operations, demonstrations, and information. An appropriation of \$1,540,780 for soil and moisture conservation investigations is continued unchanged. In addition to investigations on entire experimental drainage units, this will provide for work under controlled plot conditions on the 19 experiment stations now being maintained in 15 States.

As already noted, the act provides for the first time for the operations begun by the Agricultural Adjustment Administration and continued since February 29, 1936, under the Soil Conservation and Domestic Allotment Act. An appropriation of \$340,000,000 is made for this project, together with not to exceed \$160,000,000 of funds previously available.

The remaining work of the Department is provided for much as at present. The Bureau of Chemistry and Soils receives \$1,425,431, an increase of \$27,159, mainly for extending research on the industrial utilization of farm products; the Bureau of Agricultural Engineering, \$460,769, an increase of \$22,500 to develop data on small supplies of irrigation water and better farm buildings; the Bureau of Dairy Industry, \$703,694, an increase of \$6,600; and the Food and Drug Administration, \$2,227,758, an increase of \$150,000. There is again allotted \$75,000 for administrative purposes at the Beltsville Research Center. The Office of Information receives \$1,254,130, an increase from \$1,217,532, and the Library \$105,420, an increase from \$103,800.

The foregoing discussion does not include the Resettlement Administration, transferred to the Department of Agriculture on January 1, 1937, but still financed separately, mainly through emergency relief appropriations which aggregated to March 20, 1937, \$474,051,854. Neither has it seemed feasible to bring into the picture various supplementary funds which have been or may be available, nor to attempt to evaluate the effect of an impounding by Executive order of appropriations granted or the possibility of a subsequent reduction in these appropriations by Congressional action. The aim has been merely to attempt a comparison, based on the Agricultural Appropriation Act, as to the general outlook at this time for those agencies specifically financed by this act with their status in the previous year.

RECENT WORK IN AGRICULTURAL SCIENCE

AGRICULTURAL AND BIOLOGICAL CHEMISTRY

[Chemical investigations by the Indiana Station] (*Indiana Sta. Rpt. 1936*, pp. 62, 67).—This report briefly summarizes methodological work to serve as a basis for studies of the quality and quantity of the corn proteins. Studies on the composition and quality of soybeans are also noted.

[Chemical investigations of the Washington Station] (*Washington Sta. Bul. 342 (1936)*, pp. 74, 75).—This reports, in cooperation with the U. S. D. A. Bureau of Chemistry and Soils, beverage investigations and fruit byproducts utilization, both by H. H. Mottern, O. Johnson, and P. D. Isham.

Soluble starch: A study of its properties with a recommended supplementary procedure for determining its suitability for use in the Lintner determination, S. R. SNIDER and D. A. COLEMAN (*Cereal Chem.*, 14 (1937), No. 1, pp. 1-17).—In a joint investigation carried out by the U. S. D. A. Bureaus of Plant Industry and Agricultural Economics, the authors have brought out some important criteria for soluble starches to be used in the Lintner procedure for estimating diastatic activity. A low phosphate content as indicated by a low ash content appears to be very desirable. Freshly made solutions of the starch preparation should be used for accurate results. "Starches yielding cloudy solutions should be avoided, as the suspended undissolved particles would interfere in any gravimetric determination. Precipitation of starch will also interfere with Kjeldahl's law of proportionality. Reducing substances in soluble starch should not exceed 1 percent, in terms of maltose. Soluble starch solutions should be at least alkaline to methyl orange, and acid to rosolic acid. However, the ideal condition would be neutral to brom cresol green. . . . The erythroextrin-iodide index should not exceed 10.

"Qualifications relative to the clarity of soluble starch solutions and the rate and quantity of deposition of unchanged starches should be included as specifications for suitable soluble starches. The requirements of the A. S. B. C. and the A. O. A. C. for soluble starch for use in the Lintner determination are too severe, as no soluble starch of commercial preparation has been found which will meet their specifications."

Products of fermentation of the S and R forms of yeasts, F. W. FABIAN and L. J. WICKERHAM (*Jour. Agr. Res. [U. S.]*, 54 (1937), No. 2, pp. 147-158, fig. 1).—From determinations of the pH values and titratable acidities, volatile acids, nonvolatile acids, alcohol, and esters in the fermentation products of *Saccharomyces cerevisiae*, *S. uvarum*, *S. uvarum*, *Pichia alcoholophila*, and *Willa anomala* in cider, malt-extract broth, and a synthetic medium, the authors of this contribution from the Michigan Experiment Station conclude that "(1) in some species of yeasts there is a marked difference in the fermentation properties of the S and R forms. In other species there is little or no difference. (2) The S forms produced more alcohol in a shorter length of time than did the R forms. (3) The production of volatile acids was extremely variable. The amount produced varied with the different media, with the species of

yeast, and with the S and R forms of the different species. (4) The production of esters by the S and R forms of the four species of yeasts does not show as great variation as the production of volatile acid. There are some exceptions to this. The most important is the S form of *S. cerevisiae* Saaz in malt-extract broth and cider. In these media the amount of esters produced by the S form is practically nil, while the amount produced by the R form is 1 g per 100 cc. Another exception is in malt-extract broth, where the S form of *S. acerin-sacchari* produced 69 percent more esters than the R form. The SR form of *W. anomala* produced 30 percent more esters in cider than the R form and 61 percent more in the synthetic medium. *P. alcoholophila* produced practically no esters in any of the media.

"(5) The conditions under which the yeasts are grown influence the ester production. Sufficient oxygen to maintain normal growth produced the largest amount of esters. When there was an abundance of oxygen or insufficient oxygen no esters were produced. (6) In the yeasts which produced esters, the esters did not appear in appreciable quantities until 35 to 45 days after inoculation. Shortly after the esters appeared there was a corresponding decrease in alcohol and volatile acids. In the case of the S form of *S. cerevisiae* Saaz there was a moderate volatile acid and high alcoholic content in malt-extract broth, but practically no esters were formed. (7) The three media used affected the stability of the yeasts differently. The S and R forms of the species which grew in the synthetic medium were very stable in that medium, the S form showed no tendency to change to the R form, nor the R form to change to the S form. In the cider, however, the tendency to change was greater, and in the malt-extract broth it was still greater."

A collaborative study of the manometric determination of gassing power, R. M. SANDSTEDT (*Cereal Chem.*, 12 (1935), No. 5, pp. 517-519).—The author reports from the Nebraska Experiment Station that "the collaborative results are obviously very concordant and leave no doubt that this is a precise method, capable of giving values that can be duplicated at any time in any laboratory having the necessary pressuremeter equipment. . . .

"Five percent of yeast gives just as good checks as does 3 percent, but the gain in time by the use of 5 percent of yeast on flours of normal diastatic activity is not enough to justify its preference over 3 percent of yeast, which moreover is the amount used in the standard A. A. C. C. baking test."

On the biochemistry of the methane fermentation, H. A. BARKER (*Arch. Mikrobiol.*, 7 (1936), No. 4, pp. 404-419).—The author, at the California Experiment Station, reports upon the experiments designed to test "the hypothesis that all the methane produced by fermentation owes its origin to a reduction of carbon dioxide. This implies that the ordinary organic fermentation substrates fulfill the function of hydrogen donors for this reduction according to the equation: $4 \text{ H}_2\text{A} + \text{CO}_2 \rightarrow 4 \text{ A} + \text{CH}_4 + 2 \text{ H}_2\text{O}$. With the object of testing this hypothesis the methane fermentation of ethyl and butyl alcohols was investigated. These substrates were chosen because it was expected that they might be dehydrogenated only as far as the corresponding acids. If this happened, any methane produced could only have been formed by a reduction of carbon dioxide. The first quantitative experiment on the fermentation of ethyl alcohol showed that the fermentation proceeded in accordance with the above expectation. The alcohol was dehydrogenated almost quantitatively to acetic acid, and at the same time there was consumed a quantity of carbon dioxide equivalent to the methane formed. A second experiment completely confirmed this latter relation. These results constitute convincing proof that in this process methane arises by reduction of carbon dioxide."

An experiment with butyl alcohol as a substrate yielded results which gave additional support to the hypothesis. "Butyl alcohol is first dehydrogenated to butyric acid with simultaneous uptake of carbon dioxide, the butyric acid then being further dehydrogenated to acetic acid. Both processes are accompanied by a production of methane.

"The methane fermentation of acetic acid is regarded as being a dehydrogenation of the acid accompanied by a reduction of carbon dioxide just as are the fermentations of the alcohols; the postulated disappearance of carbon dioxide by reduction is, however, in this instance obscured by a simultaneous production of carbon dioxide as a result of the complete dehydrogenation of the acetic acid. The probable mechanism of this fermentation is expressed by the equation $\text{CH}_3\text{COOH} + 2 \text{H}_2\text{O} + \text{CO}_2 \rightarrow 2 \text{CO}_2 + \text{CH}_4 + 2 \text{H}_2\text{O}$. Evidence obtained in this investigation renders highly improbable the assumption that acetic acid can be a normal intermediate in the reduction of carbon dioxide to methane. The view is favored that this process is a plain reduction, involving the intermediate formation of one-carbon-atom compounds only."

Attention is drawn to the broader implications of the results described in regard to the mineralization of organic materials under anaerobic conditions, and the general problem of carbon dioxide reduction in natural processes.

Studies upon the methane-producing bacteria, H. A. BARKER (*Arch. Mikrobiol.*, 7 (1936), No. 4, pp. 420-433, figs. 13).—The author also presents "a survey . . . of the non-spore-forming methane-producing organisms on the basis of the rare descriptions scattered throughout the literature." The great difficulty of isolating these organisms and methods which make possible the growth of various representatives of this group in solid media are described.

"For the first time highly purified cultures of four different types have been obtained by transferring single colonies into appropriate culture media, but it has not as yet been possible to isolate strictly pure cultures. Nevertheless the purified cultures allowed of a positive identification are on the basis of morphological and physiological characters of four clearly distinct types of methane-producing organisms which have been described under the names of *Methanosarcina methanica*, *Methanococcus mazei*, *Methanobacterium sohngei*, and *M. omelianskii*."

An improved method for ashing of plant material, W. D. STEWART and J. M. ARTHUR (*Contrib. Boyce Thompson Inst.*, 8 (1936), No. 3, pp. 199-215).—Ashing of plant tissues in a muffle at 650° C. for periods of 8 and 16 hr. was compared with ashing in a combustion tube furnace for the same periods at 450° with oxygen.

Variation between duplicates and variation with repetition of ashing were less for ashing in the tube at 450° with oxygen than for the muffle at 650°. Greater losses of ash were found with increasing temperatures but little correlation with increased periods of heating. Higher ash content was found at the lower temperature. The difference consisted of increased carbonate and chloride content and higher content of volatile inorganic constituents.

The loss due to volatilization varied both with plants of the same species grown under different conditions and with different species. When the sulfates, carbonates, and chlorides of potassium, calcium, and magnesium were heated to 450°, none of these constituents were lost except chlorides of magnesium. At 650°, 700°, and 750°, both chlorides of potassium and calcium and the metals themselves were lost by sublimation. All sulfates tested were found stable at all the temperatures used.

Addition of chemicals, and especially sulfuric acid, to aid ashing resulted in higher values for the ash. In the case of the acid this increase was found

due to the conversion of chlorides and carbonates to sulfates with a resultant increase in molecular weight. Total base determinations were found to be unsatisfactory, due to nonvolatilization of phosphorus and hence incomplete conversion of bases to sulfates.

A method for ashing which was found to be superior to the usual method employed for plant material is described as follows:

"Only tissue from plants protected from spattering of soil by rain or watering should be used. The dry material is finely ground and, if a metal mill is used for grinding, any particles of metal are removed with a small magnet. Small weighing bottles are loosely filled with the material, placed in an oven at 100° for 2 hr., removed and allowed to cool over calcium chloride. Portions of 0.3 to 0.5 g are then weighed, preferably by difference in weight of bottle before and after removal of material, into tared porcelain capsules that have been cleaned well previously, burnt in a muffle at 650°, and permitted to cool in a desiccator over calcium chloride. The material in the capsules is now flamed with a lighted match before being placed in the tube for ashing, since some tissues are of such composition as to ignite explosively upon heating. The furnace should be of the combustion tube type with the heating units completely encircling the tube and with resistance units adjusted to give an operating temperature of 450°. The capsules are placed into a metal holder and so placed in the tube that each capsule is equidistant from the center of the tube. The tube is now inserted into the hot furnace, the center of the tube coinciding with the center of the furnace. A cork holding the lead from an oxygen tank is now placed in the tube and a rapid flow of dry, washed oxygen, passing through a bubble counter, is led over the samples in order to avoid explosions. After 15 min. the rate of flow of oxygen is reduced to approximately 60 bubbles per minute. After 8 hr. the samples are removed, placed in a desiccator over calcium chloride, permitted to cool, and weighed."

The determination of zinc in foods, N. D. SYLVESTER and E. B. HUGHES (*Analyst*, 61 (1936), No. 728, pp. 734-742).—The authors describe a method of extracting zinc from the ash of foods by means of diphenylthiocarbazone and a micromethod of titration of the separated zinc with potassium ferrocyanide in acetic acid solution, with diphenylbenzidine and potassium ferricyanide as internal indicators. This method is suitable for the determination of zinc in amounts of from 0.2 to 1 mg if the amounts of bismuth and cadmium present are not greater than 2 mg. Another micromethod of titration is described, which is specific for zinc and is accurate for amounts up to 0.3 mg, in which the iodine liberated from the potassium iodide in the presence of potassium ferricyanide is titrated with sodium thiosulfate solution. By this method accurate recovery of 1 p. p. m. may be obtained on a 50-g food sample. The normal zinc content of a number of food samples is given, including loganberries, raspberries, apples, carrots, potatoes, beetroot, spinach, cabbage, eggs, white and wholemeal flour, wheat germ, and wheat bran, showing a variation from 0 in the new-laid egg white to 145 p. p. m. in wheat germ.

Mercuric chloride as a preservative for milk samples held for the determination of lactic acid, H. C. TROY and P. F. SHARP (*Jour. Dairy Sci.*, 20 (1937), No. 2, pp. 77-81).—With reference to previous recommendations of the authors (*U. S. R.*, 74, p. 5) concerning the use of mercuric chloride as a preservative for milk samples held for the determination of lactic acid, further study has indicated that milk may be satisfactorily preserved up to 1 mo. when not less than 0.5 percent of mercuric chloride is added, the sample heated to 80° C. for 5 min., cooled, and held at 20° or lower, preferably in the dark.

Factors affecting maltose values in the ferricyanide method for diastatic activity. H. W. PUTNAM, M. J. BLISH, and R. M. SANDSTEDT (*Cereal Chem.*, 12 (1935), No. 5, pp. 494-504).—In an investigation reported from the Nebraska Experiment Station, the authors find it essential, for highest accuracy, that the manipulations be carried out with the least delay and with close attention to specifications. Samples treated with acetic acid reagent, as well as filtrates acid with sulfuric acid, produce higher results if allowed to stand. It is believed that aliquots alkaline with ferricyanide reagent may be stored cold for reasonable periods with but slight change. Apparent reduction in diastatic activity at room temperatures was noted, whereas no detectable changes occurred at 0° C.

Various practical suggestions are offered, covering standardization of thiosulfate, preservation of thiosulfate, convenience in handling buffer, a caution against iodine loss in hot weather, and preparation of sand for ignition.

Identification and measurement of factors governing diastasis in wheat flour. R. M. SANDSTEDT, M. J. BLISH, D. K. MECHAM, and C. E. BODE (*Cereal Chem.*, 14 (1937), No. 1, pp. 17-34, figs. 8).—It has been shown at the Nebraska Experiment Station that "the average bakers' flour contains, in addition to an abundant supply of beta-amylase, at least one other enzyme or 'activator' that affects rate of starch conversion in the autodigestion of flour or dough. This may conceivably be 'alpha-amylase', it may be 'amylase-kinase', or it may be a cytase, or a combination of these factors. . . . Flours vary as to the quantity of this factor which they contain. Soft wheat flour apparently contains very little of it, and the same is probably true of durum wheat flour.

"By far the greater portion of flour starch is 'raw' starch and unavailable to the beta-amylase that is so abundantly present, but all flours contain very significant amounts of 'available' starch as well. The available portion supposedly consists partly of ruptured or broken starch granules, and partly of starch that, due to structural peculiarities, is less resistant than the main portion. Flours vary as to quantity of available starch. Durum wheat flour contains by far the most, and soft wheat flour the least. The higher maltose value of commercial flour, as compared with experimentally milled flour, is probably due primarily to a difference in amount of ruptured starch granules.

"With the possible exception of durum wheat flour and excluding the so-called available fractions, the unruptured starch granules of various flours are for all practical purposes identical in their resistance to attack by enzymes. . . .

"The enzymes that are chiefly concerned in the autodigestion of flour starch may be almost completely and quantitatively extracted from flour by sodium chloride solutions, from which they may be precipitated with alcohol."

Reports on biological standards.—IV, The standardisation and estimation of vitamin A, edited by E. M. HUME and H. CHICK ([*Gt. Brit.*] *Med. Res. Council, Spec. Rpt. Ser. No. 202* (1935), pp. 61).—This report, which includes the complete report of the Second International Conference on Vitamin Standardization of the League of Nations (E. S. R., 73, p. 132), summarizes the work of the vitamin A subcommittee and presents a collection of technical information, most of which is not available elsewhere, concerning the properties and use of the international vitamin A standard. It is intended for the information of competent workers already practiced in the usual methods for the quantitative estimation of the vitamin.

The material is presented in three main sections dealing, respectively, with carotene as the international standard for vitamin A, the spectrophotometric method of estimating vitamin A by means of the extinction coefficient at 328 mμ, and the use of cod-liver oil as a subsidiary international standard for vitamin A.

Some of the original data upon which the report is based have been presented in journal articles by the individual workers, including Lathbury (E. S. R., 73, p. 745), Lathbury and Greenwood (E. S. R., 73, p. 881), Dyer, Key, and Coward (E. S. R., 73, p. 722), Moore (E. S. R., 71, p. 134), and Morgan, Edisbury, and Morton (E. S. R., 76, p. 4). Protocols of other experiments and certain technics are appended.

A chemical determination of aneurin (= vitamin B₁) by the thiochrome reaction, B. C. P. JANSEN (*Rec. Trav. Chim. Pays-Bas*, 55 (1936), No. 11, pp. 1046-1052).—A quantitative method of estimating vitamin B₁, based on the observation by Barger that aneurin (vitamin B₁) is oxidized to thiochrome by potassium ferricyanide in alkaline solution, is presented. The fluorescence due to the thiochrome was measured in the fluorometer, using a photoelectric cell and taking galvanometer readings. For a solution of pure aneurin, 0.1 cc (containing 1γ-20γ), was placed in a glass stoppered cylinder and 0.1 percent solution of potassium ferricyanide was added. For 1γ of aneurin from 0.01 to 0.1 cc was required, for 10γ from 0.03 to 0.1 cc, and for 20γ from 0.1 to 0.2 cc. After mixing, 3 cc of 10-percent sodium hydroxide solution was added, and the solution was again mixed and extracted within from 1 to 2 min. with 13 cc of isobutyl alcohol. The two layers were separated by centrifuging, and 10 cc was pipetted from the upper layer into the vessel of the fluorometer for reading determinations.

For the international standard adsorption powder of vitamin B₁, from 10 to 50 mg of the powder was placed in a glass-stoppered cylinder and 3 cc of the 10-percent sodium hydroxide solution was added, followed by the requisite amount of a 1-percent solution of potassium ferricyanide. If 10 mg of powder was taken, from 0.05 to 0.1 cc of the ferricyanide was needed; if 30 mg was taken, from 0.1 to 0.2 cc; and if 50 mg was taken, 0.3 cc was required. After stirring from 5 to 10 min. the mixture was extracted with 13 cc of isobutyl alcohol. Following centrifuging, 10 cc of the upper layer was measured into the fluorometer vessel. The fluorometer was standardized by the fluorescence of a solution of quinine in N/10 sulfuric acid (3 mg to 100 cc). Very good agreement was obtained between this method and the biological assay of the international standard.

The method was followed for the assay of a yeast extract to which a known quantity of aneurin had been added. Ten cc of an approximately 25-percent yeast extract in water at pH 3 was treated with 20 cc of methanol, the precipitate was removed by centrifuging, and 1 cc was mixed with from 0.1 to 0.3 cc of 1-percent ferricyanide, 1 cc of methanol, and 1 cc of 30-percent sodium hydroxide solution. This mixture was then extracted with 13 cc of isobutyl alcohol, following the procedure previously described. Alternatively, the solution from the methanol precipitation was treated with fuller's earth (300 mg per 15 cc), and the technic described for the standard powder was followed. Nearly all of the added aneurin was recovered.

Origin of vitamin C and experimental evidences supporting Sah's hypothesis, P. P. T. SAH (*Jour. Chin. Chem. Soc.*, 4 (1936), No. 6, pp. 457-462).—The author presents chemical evidence to support the theory he proposed in 1933 that L-ascorbic acid has the same origin as the sugars to which it is structurally related and, therefore, could be synthesized from D-glucose, starch, or citrus peels. Other investigators have reported the synthesis of vitamin D from D-glucose through L-sorbose. The author has obtained a synthetic L-ascorbic acid from starch.

Estimation of ascorbic acid (vitamin C) by titration, H. CHEFFTEL and M. L. PIGEAUD (*Nature [London]*, 138 (1936), No. 3497, p. 799).—When using the

Harris and Ray modification (E. S. R., 70, p. 426) of the Tillmans method, it is suggested that a more constant end point will be obtained if the ascorbic acid solution is cooled to 0° C. and the titration is carried out at this temperature, thus slowing down appreciably the oxidation and eliminating time as a fundamental factor in the results.

Sorghum sirup, G. A. SHUEY (*Tennessee Sta. Rpt. 1936, pp. 33-35, figs. 2*).—Analyses are noted and discussed.

Apple cider and cider products, J. A. CLAGUE and C. R. FELLERS (*Massachusetts Sta. Bul. 336 (1936), pp. 36, figs. 6*).—The authors take up the composition of the more important Massachusetts apple varieties, indicating the nature of the methods of analysis used; blending; pressing; clarification, including the flash heating, the gelatin-tannin, the pectinol, and the centrifugation methods; filtration, including the muslin-tube filter and filter presses and plate filters; preservation of cider, including the germ-proof filtration method, freezing storage, pasteurization, the use of preservatives, and canning; carbonated cider; concentrated cider products; uses of apple pomace; legal aspects of the alcoholic content; the spray residue problem (which is found to be unlikely to assume serious proportions in the case of eastern-grown apples, subject to abundant rainfall); and the nutritive value of cider.

The authors found the gelatin-tannin precipitation to yield a cider having a better body than that obtained by the pectinol treatment. A practical and simple procedure for testing the cider for the quantity of gelatin and tannin needed to clarify it properly is described. Practices of value in other stages of the cider-manufacturing process are also presented.

The preservation of grape juice, III, IV (*Food Res., 1 (1936), Nos. 3, pp. 301-305; 4, pp. 325-335, figs. 3*).—Parts 3 and 4 of this serial contribution (E. S. R., 76, p. 442) from the New York State Experiment Station are given.

III. *Studies on the cool storage of grape juice*, C. S. Pederson.—The author shows that in general the yeasts and bacteria contained in grape juice slowly die out during low temperature storage. "This is gradual, but apparently begins immediately after the low temperature is attained in the juice.

"In spite of the results here obtained, samples of grape juice have fermented in cold storage. It is difficult to account for this fermentation. It may be due to excessive growth of yeast prior to cooling, resulting in fermentation after cooling and before actual death of organisms takes place. Since in examination of a few samples, however, a high count of yeast was usually found, it seems more logical that certain strains become acclimated, grow, and ferment the product.

"Occasionally mold developed in the samples. Mold has been noted on a number of occasions on juice in cold storage, even though the juice has been frozen. It seems that the only safe method of eliminating mold is to exclude air from contact with the juice.

"From the standpoint of the quality of the juice itself, there is little doubt that this method of storage favors the retention of the natural aroma and flavor. It furthermore results in a more rapid precipitation of the argols and in a clearer juice."

IV. *Pasteurization of juices or musts prepared from several varieties of grapes*, C. S. Pederson, E. A. Beavens, and H. E. Goresline.—The authors report upon experiments in which "temperatures attained in the juice were determined by means of thermocouples connected to an electropotentiometric thermometer, and the rate of killing of micro-organisms was determined by platings of the juice during pasteurization at 1-min. intervals.

"In samples of juice prepared from Fredonia, Ontario, Niagara, Elvira, Concord, and Catawba grapes the numbers of living micro-organisms were markedly reduced when a temperature of 62.8° C. (145° F.) was attained, and all micro-organisms were killed by heating to 73.0°. Pasteurization temperatures from 54.4° to 60° reduce the number of micro-organisms present in grape must sufficiently so that a pure-culture inoculum of yeast will ordinarily control the fermentation. Pasteurization at such temperatures is unlikely to produce off-flavors in the must. The numbers of living organisms in juice prepared from California Muscat grapes were markedly reduced at 62.8°, but spore-forming bacteria were still present after the juice was heated to 76.7°. The addition of small quantities of sulfur dioxide lowered the temperature required for killing of organisms but not sufficiently to recommend its use. Stirring of juice is essential to uniform heating. Foam on the surface of the juice serves as a good insulator protecting organisms present in the foam from heat effects."

AGRICULTURAL METEOROLOGY

A brief list of works on meteorology, compiled by R. T. Zoch (*U. S. Mo. Weather Rev.*, 65 (1937), No. 1, pp. 1-3).—This is a selected classified list of some of the more important works on meteorology and climatology, including a number which relate more particularly to agricultural meteorology.

United States Meteorological Yearbook, 1935 (*U. S. Met. Yearbook 1935*, pp. II+140, figs. 4).—This yearbook, which was formerly issued as a report of the Chief of the Weather Bureau, contains a general summary of weather conditions in the United States during the year 1935 (El. S. R., 75, pp. 589, 590) and annual meteorological summaries, 1935, which have been previously noted from other sources.

Weather of 1936 in the United States, J. P. KOHLER (*U. S. Mo. Weather Rev.*, 65 (1937), No. 1, pp. 12-16, pls. 2).—Summarizing briefly the outstanding features of the weather of the year, the author says: "The weather during the year 1936 was characterized by marked extremes in temperature and precipitation. Unparalleled prolonged periods of subzero temperatures obtained in many Western States in the early months of the year followed by unprecedented drought conditions during the summer months."

Climatological data for the United States by sections, [January-December 1935] (*U. S. Dept. Agr., Weather Bur. Climat. Data*, 23 (1936), Nos. 1-12, [about 200 pp., 3 pls., 3 figs. each]).—These numbers contain the usual brief summaries and detailed tabular statements of climatological data for each State.

Monthly Weather Review, [January-February 1937] (*U. S. Mo. Weather Rev.*, 65 (1937), Nos. 1, pp. 42, pls. 13, figs. 6; 2, pp. 43-96, pls. 11, figs. 21).—In addition to the usual detailed summaries of climatological data, solar and aerological observations, observations on weather on the Atlantic and Pacific Oceans and on rivers and floods, and bibliographical and other information, these numbers contain the following contributions:

No. 1.—A Brief List of Works on Meteorology, compiled by R. T. Zoch (pp. 1-3) (see above): An Observation of Anticrepuscular Rays, by J. G. Albright (p. 3); The Geometrical Theory of Halos, II, by E. W. Woolard (pp. 4-6) (El. S. R., 76, p. 588); Tables for the Computation of Halos, by C. M. Lennahan (pp. 7, 8); Atmospheric Waves on Isentropic Surfaces as Evidenced by Interfrontal Ceiling Oscillations, by W. C. Jacobs (pp. 9-12); and Weather of 1936 in the United States, by J. P. Kohler (pp. 12-16) (see above).

No. 2.—A Semi-quantitative Method of Forecasting Summer Stratus in North American Tropical Maritime Air, by J. J. George and W. M. Bradley (pp. 43-46); Temperature and Rainfall Changes in the United States During the Past 40 Years, by L. F. Page (pp. 46-54); The Geometrical Theory of Halos, III, by E. W. Woollard (pp. 55-57) (see above); An Unusual Reflection of Sunlight From Alto-Cumulus Clouds, by G. M. French (pp. 58, 59); and Note on the Hurricane of August 5 to 8, 1936, in Mexican West Coast Waters, by D. Blake (p. 59).

North Carolina rainfall, L. A. DENSON (*Jour. Amer. Water Works Assoc.*, 28 (1936), No. 4, pp. 479-483, figs. 3).—It is shown that the rainfall of North Carolina varies widely, seasonally and locally. The area of heaviest rainfall is an abrupt slope above 3,000 ft. overlooking portions of Georgia and South Carolina, where it is about 70 to 75 in. annually. In most of the Piedmont and part of the Coastal Plain the rainfall varies from slightly under 45 to about 50 in., while on a part of the lower coast section it is between 50 and 55 in., with a small area near New Bern in which the rainfall is 56 in. Seasonally, the distribution is on the whole favorable to agriculture and water supply. "The rainfall increases as winter comes on and . . . there is a pick-up in ground supply in the dormant season until March. Then there is a drop of 0.75 in. in April or planting time when less rain is needed. From May to July there is an increase through the period of cultivation and July and August have the greatest amounts during development and maturity of crops, finally followed by a decline through autumn when dry weather is needed for harvesting."

Teleconnections of climatic changes in present time, A. ÅNGSTRÖM (*Geogr. Ann.*, 17 (1935), No. 3-4, pp. 242-253, figs. 7; *abs. in Geogr. Rev.*, 26 (1936), No. 4, pp. 688-690).—On the basis of his own observations and those of others, the author discusses factors that may produce widespread simultaneous climatic fluctuations as follows:

"(1) Changes in the amount of solar energy reaching the earth, resulting from variations in (a) amount of radiation reaching the upper surface of the atmosphere (i. e., the solar constant), (b) transmission of radiation by the clear atmosphere, and (c) mean cloudiness; (2) changes in the atmospheric circulation; [and] (3) changes dependent on phenomena whose influence on weather is still obscure, such as corpuscular radiation from the sun and number of nuclei of condensation." He concludes that "the interaction of the processes of radiation and circulation is so close, and the results of the interaction are so complex, that discovery of the causes of a given climatic fluctuation by empirical analysis is difficult if not impossible. Therefore empirical investigation must be preceded and accompanied by theoretical clarification of the effects of variations in the factors named."

Introductory note on the geological foundations of the soils of India, D. N. WADIA, M. S. KRISHNAN, and P. N. MUKERJEE (*Rec. Geol. Survey India*, 68 (1935), No. 4, pp. 363-391, pls. 2; *abs. in Geogr. Rev.*, 26 (1936), No. 4, pp. 686, 687).—The author attempts to correlate mean annual rainfall and rainy days with certain characteristic soil types in India. He finds that "black soil, the 'regur' of Indian terminology . . . occur[s] where the annual rainfall is between 500 and 800 mm and the rainy days are 30 to 50; it is also found, exceptionally, in the higher Western Deccan in places having 1,000 mm a year and more rainy days than 50." He notes that forest soils of the South Indian plantations form a transition between regur and the laterite, and confirms the generally accepted view that regur and laterite are essentially mature formations and the expression of relief and climate, not geology.

SOILS—FERTILIZERS

[Soil research by the Illinois Station] (*Illinois Sta. Rpt. 1935, pp. 14-39, figs. 7*).—Data are reported on soil fertility as explained by long-time processes, by E. E. DeTurk, R. H. Bray, F. E. Condo, R. E. Grim, and P. F. Kerr; leaching studies in relation to good cropping systems, by DeTurk and J. C. Anderson; variations in soils as complicating land-use problems, by F. C. Bauer, A. L. Lang, L. B. Miller, C. J. Badger, C. H. Farnham, and P. E. Johnson; sound management methods and the net value of land, by Bauer, Lang, and Miller; soybean hay and seed yields sensitive to soil fertility, by Bauer, Lang, et al.; fall cutting reduces soil improvement from sweetclover, by Bauer, Lang, H. J. Snider, and Farnham; manure and lime powerful aids in soil conservation, by Bauer, Lang, et al.; lime-legume treatment may affect phosphorus supply and potassium needs not always met by legume-lime system, both by Bauer and Snider; and balancing plant food insures better yields of corn, by O. H. Sears, L. E. Allison, Bauer, Snider, and DeTurk.

[Soil investigations by the Indiana Station] (*Indiana Sta. Rpt. 1936, pp. 16-18, 62-64, figs. 5*).—This report contains brief summaries of soil work under the following captions: Manure varies in value with the kind of soil on which it is used, importance of phosphate fertilizer on "clay" soils of east-central Indiana, nitrogen top dressing of winter small grains on sandy soils, factors affecting the efficiency of phosphate fertilizers, rock phosphate not a substitute for limestone in producing nonacid-forming fertilizers, relative fertility of surface soils and their subsoils, determination of equivalent acidity and basicity of fertilizers, the available phosphorus and potassium contents of the principal soil types in Indiana, the availability of magnesium in fertilizers, crop responses to fertilizer additions and fertilizer deficiency symptoms, and determination of available potash in commercial fertilizers.

[Soil and fertilizer work by the Tennessee Station] (*Tennessee Sta. Rpt. 1936, pp. 6-8, 13, 14, 27-31, fig. 1*).—This report contains findings on a soil survey of Jefferson County; short methods for determining the fertilizer requirements of a soil; fertilizer experiments, by H. P. Ogden; and on lysimeter studies on magnesium and sulfur as plant nutrients, lime-potash relationships, liming problems, migration of phosphates, recoveries of fertilizer nitrogen, and new phosphates (calcium metaphosphate and a new type of glassy calcium phosphate), all by W. H. MacIntire and W. M. Shaw.

[Soil investigations of the Washington Station] (*Washington Sta. Bul. 342 (1936), pp. 14-19, 65, 66*).—This report contains concise summaries on mineral supplements to manure, the maintenance of organic matter in eastern Washington soils, utilization of fertilizers on representative upland soils in western Washington, and changes occurring in irrigated soils as a result of irrigation, cropping, and fertilizer treatments, all by L. C. Wheeting and S. C. Vandecaveye; composition of grasses and hays as influenced by variation in climate and soil type, by Vandecaveye, L. T. Kardos, and Wheeting; maintenance of organic matter in central Washington, by Wheeting, Vandecaveye, and C. I. Seely; investigations of the effect of accumulations of arsenical sprays in orchard soils to their loss in productivity, by Kardos, Vandecaveye, and C. M. Keaton; and reclamation of saline soils, by C. A. Larson.

The universal soil testing system, M. F. MORGAN (*Connecticut [New Haven] Sta. Bul. 392 (1937), pp. 125-159, pls. 8*).—This revision of Bulletin 372 (E. S. R., 73, p. 746) includes a few minor changes and additions in the methods and their interpretation.

Soil colors measured by the disc color analyser, C. F. SHAW (*3 Internat. Cong. Soil Sci., Oxford, Eng., 1935, Trans., vol. 3, pp. 78-81, figs. 4*).—By means

of color disk standards rotated with the sample (which consisted of a thin layer of the soil dried on a small disk of blotting paper) (E. S. R., 67, p. 212), the author of this contribution from the California Experiment Station determined the color composition, in terms of black, white, yellow, and red, of the soils qualitatively designated in soil survey reports, etc., as shades of gray, brown, or red.

"The variation in the composition of the color as shown by these studies makes apparent the need of the establishment of more definite standards for soil colors and for an agreement on the color nomenclature. There is also need for determining the degree of variation in composition permissible within any one color designation. What variation in shade or hue is permissible in a 'brown' soil? When does it become a 'light brown' or a 'reddish brown?' . . . Much time and effort is being devoted to devising and standardizing methods of mechanical analysis. Corresponding efforts may well be applied to the problems of soil color. Not only is there need for comparable color measurements by many soil scientists, but there is also need that samples of the same soil be exchanged and measured in several laboratories to determine the consistency in analytical results and the degree of agreement on color designations. . . .

"Soil colors are distinct and definable. They can be measured and their composition reported in brief and specific terms. Therefore the use of soil color designations can be standardized and established by international agreements."

The mineralogical study of the soils [trans. title], V. AGAFONOFF (*3. Internat. Cong. Soil Sci., Oxford, Eng., 1935, Trans., vol. 3, pp. 74-78, figs. 2*).—The author calls attention to the importance of two methods of mineralogical soil study, namely, the microscopic examination of thin layers specially prepared for this purpose and the study, by means of thermocouples placed in a soil sample electrically heated in a silica tube, of the endothermic and exothermic breaks in the temperature curve produced when the sample is heated evenly to 1,000° C. The inflections in the heating curves are attributed to the driving out of water and to decompositions and transformations of the mineral components of the soil. Kaolinite, for example, together with mixtures containing 50 percent or more of this mineral, showed a definite exothermic inflection of the heating curve at a temperature between 900° and 950°. With 10 percent of kaolinite in the mixture the inflection is shown as still clearly detectable, but at 5 percent the effect upon the form of the curve is very slight in the figures presented.

The chemical composition and crystal structure of clay minerals, C. E. MARSHALL (*3. Internat. Cong. Soil Sci., Oxford, Eng., 1935, Trans., vol. 3, pp. 95-97*).—The author discusses the clay minerals from the point of view of certain discrepancies between formulas based on chemical analyses and formulas derived from X-ray data. It is noted that "in the kaolinite-halloysite group of clays the chemical formulas and the X-ray structures are in good accord. The structures are layer lattices composed of $\text{Al}_2(\text{OH})_4$ sheets alternating with $\text{SiO}_2\cdot(\text{OH})_2$ sheets. In halloysite these are simply stacked together, giving the formula $\text{Al}_2\text{O}_3\cdot 2\text{SiO}_2\cdot 4\text{H}_2\text{O}$. In kaolinite and dickite, and probably also in nacrite, water is eliminated between OH groups of adjacent layers, giving a closer approach of the Si and Al atoms. The three isomers differ in the geometrical positions in which the layers are stacked above one another, and all have a reasonably constant formula $\text{Al}_2\text{O}_3\cdot 2\text{SiO}_2\cdot 2\text{H}_2\text{O}$. In this group, therefore, which is composed of clays having little base-exchange capacity, the X-ray and chemical formulas are in perfect agreement."

In the case of beidellite and montmorillonite, formulated, respectively, as $\text{Al}_2\text{O}_3 \cdot 3\text{SiO}_2 \cdot n\text{H}_2\text{O}$ and $\text{MgO} \cdot \text{Al}_2\text{O}_3 \cdot 5\text{SiO}_2 \cdot n\text{H}_2\text{O}$ the X-ray photograph was the same for each mineral and indicated a structure of the form $\text{Al}_2\text{O}_3 \cdot 4\text{SiO}_2 \cdot n\text{H}_2\text{O}$. "In attempting to resolve these differences it was necessary to proceed very cautiously and to go right back to the actual analyses on which the chemical formulas were based. Since it was quite clear that the clays are built up of the layer lattice units which have already been described, the analyses were recalculated so that they could be compared with various lattice types consisting of different numbers of Al and Si layers. The following replacements were then assumed to operate in order to complete the lattice framework. Aluminum was assumed to replace silicon as in the micas and feldspars. Magnesium was assumed to replace aluminum as in talc and the chlorites. Each of these replacements demands one equivalent of a cation in order to balance the resultant charge on the framework. In addition ferric iron was assumed to replace aluminum. In this way the published analyses of montmorillonites, beidellites, and nontronites were compared with the ideal lattice types. It was found that although a single analysis might be represented equally well by two different lattice types there was only one type which fitted all the montmorillonite and all the beidellite analyses. This was the type $\text{Al}_2\text{O}_3 \cdot 4\text{SiO}_2 \cdot n\text{H}_2\text{O}$, corresponding to two Si layers for each Al layer. In the beidellites the predominant replacement was that of Al for Si. In the montmorillonites there was generally a predominant replace of Mg for Al, but it was usually accompanied by a considerable replacement of Al for Si. In both cases Fe could replace Al, and this replacement carried to completion leads eventually to nontronite. Certain other nontronites show compositions suggesting that they are derived from the halloysite type rather than from the beidellite type. Finally, when the clay subfractions which have been intensively studied in this laboratory were analyzed, it was realized that two other substitutions in the lattice were probable, namely, that of phosphorus for silicon and that of tetravalent titanium for aluminum. The importance of the former needs no emphasis."

Briefly considering the base-exchange mechanism in the light of the observations mentioned above, the author finds that "a small fraction only of the exchange capacity is due to the cations in the electrical double layer surrounding the particles." He also shows that the new information necessitates modifications in some of the current views of the relation between base-exchange capacity and the silica:sesquioxide ratio.

On the state of the clay substances of the oxyphilic volcanic ash soils [trans. title], M. SHERER (*3. Internatl. Cong. Soil Sci., Oxford, Eng., 1935, Trans., vol. 3, pp. 70-73*).—The isoelectric point of the argillaceous material of the lower layer, poor in humus, of the oxyphilic volcanic ash soils studied was found to lie close to pH 7. In the upper layers, relatively rich in humus, the isoelectric point was found at somewhat lower pH values. After such soil had been held in a moist state the electrical charge of the clay substances when dispersed in water was positive, whereas, at least in the upper layer, the undisturbed soil in its natural state showed either no charge or a weak negative charge. This is taken to indicate that in their natural state these soils are practically isoelectric with the soil water and have attained a stable condition.

Hydration of minerals and soil colloids in relation to crystal structure, W. P. KELLEY, H. JENNY, and S. M. BROWN (*3. Internatl. Cong. Soil Sci., Oxford, Eng., 1935, Trans., vol. 3, pp. 84-87, figs. 4*).—The authors report from the California Experiment Station a comparative study of dehydration curves of

ground minerals and soil colloids. The substances were brought to equilibrium with water vapor over 50 percent sulfuric acid, and subsequently the water loss was measured at various temperatures up to 800° C. They discuss the bearing of the results obtained upon questions of crystal lattice structure and of forms of adsorbed water in the individual minerals examined and of the nature of soil colloid structure.

With regard to adsorbed water, it is pointed out that "if one sets all adsorbed water equal to 100 percent and then plots the relative water losses against temperature, one finds differently shaped curves which point to the existence of various forms of adsorbed water. Feldspars lose their adsorbed water at a relatively constant but low rate, while bentonites give off over 80 percent of their hydration water below 100° or 150°. Feldspar water is held tightly, whereas bentonite water is loosely bound. The authors believe that on feldspars the adsorbed water molecules are attracted by the free electric fields of exposed O⁻, Al⁺⁺⁺, and Si⁺⁺⁺⁺ ions, and they designate this form of adsorbed water as broken bond water. In the case of bentonites and related minerals the neutral O⁻ and OH⁻ planes are also able to polarize water molecules, but only by weak electric stray forces, and consequently the molecules escape at very low temperatures. This type of adsorbed water is termed planar water. At the edges of the planes broken bond water also occurs. In any mineral consisting of O and OH sheets the relative proportion of the two types of water depends on the extent of the exposed planes as compared with that of the areas vertical to them."

The curves plotted for the soil colloids investigated "suggest that the soil colloids are of platy nature and are composed of O⁻ and OH⁻ planes. The number and arrangement of the planes within the particles appear to differ in certain respects from those of known minerals. However, the nature of the exposed surfaces of the soil colloids greatly resembles those of bentonite and beidellite."

The evidence as to the crystallinity of soil colloids, W. P. KELLEY (*3. Internat. Cong. Soil Sci., Oxford, Eng., 1935, Trans., vol. 3, pp. 88-91*).—In support of the view that the soil colloids are of a microcrystalline structure, the author of this contribution from the California Experiment Station cites in brief summaries the X-ray evidence, the indications found in optical properties of all the soil colloids thus far examined, the effects upon the X-ray spectrographs produced by grinding soil colloids, and the results of dehydration studies, including the effect of dehydration upon the X-ray spectrographic picture. All of these various lines of attack upon the problem yielded evidence indicative of crystalline structure.

The significance of crystallinity in relation to base exchange, W. P. KELLEY (*3. Internat. Cong. Soil Sci., Oxford, Eng., 1935, Trans., vol. 3, pp. 92-95*).—In part from the data discussed in the paper above noted, the author of this contribution from the California Experiment Station concludes that "the exchange capacity of a soil colloid depends on two variables, first, the kind of exposed surfaces on its individual particles, second, the amount of surface. The kind of surface is determined by the crystal structure and therefore the kind of mineral that we are dealing with. The amount of surface depends on the particle size."

On the formation of structure in soil.—III, Mechanism of the swelling of soil, D. I. SIDDER (*Soil Sci., 43 (1937), No. 1, pp. 43-49, pl. 1*).—Continuing the experiments of a series recently noted (*Ed. S. R., 77, p. 16*), the author finds that "water absorption and swelling of soil are determined by the structure of the surface layer of oriented particles.

"Particular importance is attached, in the case of unstable groupings, to the compactness of the particles at the interface solid phase-air. Mechanical damaging of the surface layer leads to disintegration. From the viewpoint of the new conceptions concerning soil structure it becomes necessary to revise the theory of soil morphology. There is no other field . . . in which the internal relation between the shape of the molecule and the crystal would appear with such clearness as in the mesomorphous state."

Ionic exchange and structure [trans. title], G. WIEGNER (*3. Internat. Cong. Soil Sci., Oxford, Eng., 1935, Trans., vol. 3, pp. 5-28, figs. 6*).—A large part of this paper is given over to a historical review of the development of the theory of the structure and formation of the colloidal micelle. Some new experimental matter is also dealt with.

It is shown that a difference between the surface structures of the outer and inner exchange layers may lead to the setting up of a different metastable structural equilibrium at each layer. The exchange occurring in complexes of the same analytical composition may lead to very different results if the exchange ions are attached to different parts of the surface layer.

The types of alkali soils (Solonetz) [trans. title], V. A. KOWDA (*3. Internat. Cong. Soil Sci., Oxford, Eng., 1935, Trans., vol. 3, pp. 99-102*).—The author distinguishes five classes of "alkali" soils which he gives the respective designations Solonchak-like Solonetz, residual Solonetz resembling Solonchak, gypsum-free alkali Solonetz, soda Solonetz, and soda Solonetz-Solonchak. These forms of alkali soil are, in the order in which they are named, the successive stages of development. In the description of the series the bases of distinction between the successive stages are emphasized.

Cellulose decomposition in acid soils, H. KAENICKA and J. ZIEMIĘCKA (*3. Internat. Cong. Soil Sci., Oxford, Eng., 1935, Trans., vol. 3, pp. 109-111*).—The authors here summarize an investigation of which the results are to be more fully presented elsewhere. They have found, in part, that "two main groups of micro-organisms seem to be specially adapted in our soils to aerobic cellulose decomposition, namely, molds and bacteria. Actinomycetes have been found, however, to develop well as secondary agents in cellulose decomposition. Their role in this process still needs a special study. The direct action of bacteria on cellulose in the soils seems to be limited to the base-saturated soils. At a pH higher than 6.5, bacteria were almost the only agents of cellulose destruction. In slightly acid soils, or at a pH of 6.0-6.5, the cellulose was attacked by bacteria, by molds, and by some actinomycetes. In soils poor in humus and with a pH less than 6.0 no growth of specific cellulose bacteria was ever found, and actinomycetes have been noted only occasionally. In such soils the cellulose was decomposed by molds. . . . Lime was found in the above soils to be a negative factor in cellulose destruction, as no cellulose bacteria ever appeared, and the activity of the molds suffered from this treatment. Nitrogen was the essential positive factor both for the density of the specific mold population and for its activity in the soil. A close correlation was found to exist between the ability of cellulose decomposition in the soils and their average cereal crops, except in the case of soils treated with both lime and nitrogen. . . .

"The rate of cellulose decomposition in the acid or 'mold soils' that were studied increased nearly to 100 percent with the addition of minerals and nitrogen in the absence of liming, but it never reached the level of cellulose destruction which was found in base-saturated, neutral soils. These 'bacteria soils' contained a very rich population of cellulose bacteria (*Spirochaeta cytophaga* and others) and were found to destroy nearly twice as much cellulose, in the given unit of time, as did the most fertile plats from the acid

field. . . . In base-saturated, neutral soils molds and actinomycetes developed only after the first attack of bacteria on cellulose, and the tertiary microbial growth consisted, just as in acid soils, of weakly staining thin rods and cocci feeding on the decaying organisms. A rich protozoan growth took place very often in these soils."

Broad relationships between micro-organisms and soil fertility, J. G. LIPMAN (*3. Internat. Cong. Soil Sci., Oxford, Eng., 1935, Trans., vol. 3, pp. 29-44, fig. 1*).—Recent progress in soil microbiology is here reviewed, with citations of more than 130 papers, by the director of the New Jersey Experiment Stations. The discussion takes up some of the recent observations concerning soil micro-organisms, methods, environmental conditions (including temperature, the nature and concentration of the salts present, moisture, reaction, aeration, and organic matter), and interrelations between higher plants and micro-organisms (including antibiotic phenomena, associations of legumes and nonleguminous plants, and plant stimulants and accessory food substances).

Does photo-nitrification occur in soils? N. V. JOSHI and S. C. BISWAS (*3. Internat. Cong. Soil Sci., Oxford, Eng., 1935, Trans., vol. 3, p. 104*).—The authors report very briefly upon experiments on the formation of nitrates from ammoniacal compounds and of ammonium compounds from nitrogenous organic substances. The soils tested were an acid soil from Dacca and a calcareous soil from Pusa. Attempts to find indications of photonitrification in culture solutions were also carried out. "In none of these soils after sterilization could we obtain nitrate formation from the added ammonium salts or from urea or farmyard manure, even after long exposure of the soils to sunlight. Soils without sterilization, with their nitrifying flora alive, did not show any increased nitrate formation by exposure to sunlight. On the other hand, there was depression in nitrate formation in soils exposed to sunlight. This depression is surmised to be chiefly due to the lowering of the activity of the nitrifying organisms, caused by raising of the temperature of the soil on account of exposure to the sun's rays." Peptone and urea culture solutions also failed to show any photoammonification.

"It appears, therefore, that the hypothesis of photonitrification is not proved, and that any expectations that might have been aroused of putting it to practical use in reclaiming infertile soils by stimulating such soils by exposure to sunlight are unlikely to be realized."

The formation of nitrite by heterotrophic bacteria from soil, L. M. CRUMP (*3. Internat. Cong. Soil Sci., Oxford, Eng., 1935, Trans., vol. 3, pp. 103, 104*).—The author finds that "there are a relatively large number of heterotrophic soil bacteria which under very varied conditions produce nitrite in small amounts from ammonia. These forms require organic matter for their satisfactory growth and carry out their chemical transformations at pH values anywhere between 5.0 and 8.0. As yet there is no evidence of different morphological stages in the course of the life cycle, and the great majority are short rods or cocci. There is also no indication that in any other respect do they fall into any one physiological grouping. To some extent a correlation can be traced between the increase in their numbers in a culture and the increase of nitrite, but this breaks down in the case of those organisms that utilize nitrite in the course of growth."

Soils of Cascade County: Soil reconnaissance of Montana.—Preliminary report, L. F. GRESSEMER (*Montana Sta. Bul. 337 (1937), pp. 66, fig. 1, maps 4*).—The county covered by this reconnaissance survey occupies 2,747 sq. miles in central Montana. Its lands form, for the most part, a transitional area between mountain groups and rolling drift-covered plains.

In the survey here noted, the soils found were classified as 45 types assigned to 25 series. The Morton silt loams were found to cover 9.6 percent of the area surveyed, the Teton stony loams 9.4 percent. Mountains occupy 25.6 percent.

Methods of conserving Michigan muck soils, P. M. HARMER (*Michigan Sta. Quart. Bul.*, 19 (1937), No. 3, pp. 182-191, figs. 8).—The author finds that muck soils, as usually used, are likely to be short lived by reason of "three agents of destruction—(1) excessive chemical decomposition, (2) fire, and (3) wind.

"Practical methods of restoration of depleted mucks and of prevention of future depletion include (1) maintenance of as high a water level in the soil as the root systems of the crops being grown will permit, (2) use of wind-breaks and interplanted grain for wind protection, (3) use of organic matter in form of manure or green manure for wind protection and soil improvement, (4) heavy compaction of excessively drained soils, (5) addition of various plant food materials which may have been largely removed by wind erosion and cropping methods."

Measures (1) and (4) are directed against excessive aeration and the concomitant oxidation of the organic components of muck soils.

Soils in relation to fruit growing in New York.—X, Susceptibility of various New York orchard soils to reduction upon water-logging, M. PEECH and D. BOXTON ([*New York Cornell Sta. Bul.* 667 (1937), pp. 20, figs. 4).—The authors here record an extension of work previously noted (E. S. R., 76, p. 302), endeavoring to determine the cause of some of the discrepancies between the redox potentials of soils as measured in 0.1 N H₂SO₄ suspensions and their drainage conditions.

"It was found that manganese concretions which are likely to be present in soils subject to waterlogging introduce an inherent error in this method. The oxidation of ferrous sulfate by manganese concretions proceeded very rapidly. Even an immediate measurement of the redox potential of a reduced soil containing active forms of manganese concretions did not eliminate this error.

"The effect of time of suspension in acid upon the final value of the redox potential was investigated also. As might be expected, the reduced soils showed a greater increase in Eh with time than did the well-oxidized samples of the same soils."

The redox potentials of some orchard soils in situ and in 0.1 N H₂SO₄ suspensions of these soils were measured frequently during a 30-day period. "The redox potentials measured in situ in many cases showed higher intensity of reduction in subsoils than in corresponding surface samples during the early stages of the experiment. In a few soils, potentials as low as that of the hydrogen electrode were developed within a few hours after waterlogging. At the end of the experiment, most of the surface soils had lower redox potentials than had the corresponding subsoils. Well-drained types of subsoils were as susceptible to reduction upon waterlogging as were poorly drained types. In general, subsoils of light texture, which had wider C:N ratios, were more susceptible to reduction than were heavy subsoils, which had narrower C:N ratios."

Means for the determination of the mode of action of drainage systems, canals, and tile drains [trans. title], E. DISERENS (*3 Internat. Cong. Soil Sci., Oxford, Eng., 1935, Trans., vol. 3, pp. 45-69, figs. 7*).—The author points out various ways in which drainage works, both canals and tile, influence the circulation of water in the soil, the aeration, the temperature, the permeability,

condensation and evaporation, and the capacity of the soil to absorb fertilizers. Of these effects, that exerted upon the movement of water in the soil is emphasized as of outstanding importance to the proper operation of drainage systems. The general term "permeability" is held to cover two distinct characteristics or constants of the soil, both readily subjected to accurate measurement, namely, rapidity of filtration and permeability proper. It is further pointed out that, except in the case of sands which have no structure, there are differences between laboratory and field data representing the constants named, so that these constants, to be used as a guide in connection with drainage and irrigation works, should be determined in the field.

Other physical characteristics of soils are also discussed with respect to their relation to drainage systems and the effects of such works upon soils.

One of the points emphasized is that soil drainage systems are to be recommended not merely in regions of high or moderate humidity but also in areas where soils of little permeability are used under irrigation.

[Erosion studies by the Washington Station], G. M. HORNER and P. C. MCGREW (*Washington Sta. Bul. 342* (1936), pp. 69-71).—Progress results are briefly reported of investigations on effect of plant cover on run-off and erosion, movement and balance of soil moisture, tillage and cultivation practices for erosion control, cropping practices in relation to erosion control, terracing, gully control, tree planting for erosion control, and wind erosion.

Handbook of erosion control engineering on the national forests, E. W. KRAMER, A. L. ANDERSON, and M. B. ARTHUR (*U. S. Dept. Agr., Forest Serv., 1936*, pp. VI+90, figs. 72).—The purpose of this handbook is to serve as a guide in carrying on erosion control work in the national forests. It emphasizes the control measures which apply to comparatively undeveloped or forested types of land rather than those for agricultural or cultivated areas. The greater part of the handbook deals with the design and construction of engineering structures which have proved practicable for erosion control work, and with the considerations which affect the choice and use of these structures. It contains chapters on the erosion problem on national forests, erosion control measures, hydraulics of erosion control, gully structures, estimated cost of restoring a gully, soil saving and debris dams, and miscellaneous structures.

Preventing soil blowing on the southern Great Plains, E. F. CHILCOTT (*U. S. Dept. Agr., Farmers' Bul. 1771* (1937), pp. [2]+29, figs. 21).—Tillage practices and implements used for the prevention of soil blowing are described, together with cropping practices.

Fertilizer analyses for different North Carolina crops, including the best percentages of water-insoluble nitrogen of totals in fertilizer mixtures recommended (*North Carolina Sta. Agron. Inform. Circ. 107* (1937), pp. 12).—Formulas of fertilizer mixtures and recommended quantities of these fertilizers are given for various crops and groups of crops grown on the several soils of the State.

Liming Coastal Plain soils, J. B. HESTER, M. M. PARKER, and H. H. ZIMMERLEY (*Virginia Truck Sta. Bul. 91* (1936), pp. 1303-1358, figs. 14).—Part 1 of this bulletin deals with the yields of certain crops when grown on specific types of soils with a known reaction. Based on these yields, general recommendations are made concerning the optimum soil reaction range to be maintained. "It is realized that due to the great variation in soils no two of them are apt to produce identical results from any given treatment, but in general these recommendations, if modified when necessary, should be applicable."

Part 2 "deals with a more or less technical discussion of the various aspects of liming the soil."

Effect of calcium cyanamide on the soil microflora with special reference to certain plant parasites, C. M. HAENSELER and T. R. MOYER (*Soil Sci.*, 48 (1937), No. 2, pp. 133-151, pl. 1).—In the greenhouse pot experiments reported in the present contribution from the New Jersey Experiment Stations, calcium cyanamide applied to the soil in quantities as large as 10,000 lb. per acre caused a marked change in the number of fungi, bacteria, and actinomyces as determined by the plating method. A greater decrease in the number of fungi resulted in soils near the neutral point in reaction than in more acid soils. After calcium cyanamide was applied to the soil, the number of bacteria and actinomyces decreased temporarily, then increased very rapidly for about 30 days, after which they again decreased to the normal. In one case the number of bacteria in the treated soil was 92 times the number in the untreated soil. "The effect of calcium cyanamide on the soil microflora seemed to be more closely correlated with the soil reaction than with the quantity of material used."

The effect of calcium cyanamide in controlling certain soil-inhabiting plant pathogens was also studied. This fertilizer was very effective as a control for some organisms. In soil infected with *Plasmodiophora brassicae*, for example, "in greenhouse tests calcium cyanamide was about two and one-half times as effective as an equal quantity of hydrated lime in controlling clubroot infection shortly after application."

Toxicity of arsenic, borax, chlorate, and their combinations in three California soils, A. S. CRAFTS and C. W. CLEARY (*Hilgardia* [*California Sta.*], 10 (1936), No. 10, pp. 399-413, figs. 3).—In the greenhouse experiments described, sodium arsenite, hydrous sodium tetraborate, and sodium chlorate were used singly and in combination in concentrations which reduced the growth of indicator plants to 50 percent and to 10 percent of the normal.

"Arsenic and borax showed antagonistic reaction in Yolo clay loam at both the 50 percent and the 10 percent growth levels. Arsenic and borax toxicities were additive in Fresno sandy loam and Stockton adobe clay. Arsenic and chlorate toxicities were additive in all three soils at both growth levels. Borax and chlorate showed antagonistic reactions in all three soils at both growth levels.

"The combination of the chemicals used three at a time are of only theoretical interest and provide no practical information. In the practical application of these chemicals the arsenic-borax combination would find little use. Sodium chlorate and white arsenic applied dry form a very useful mixture for soil sterilization. As shown by the greenhouse experiments, there is no indication of loss by antagonism in their reactions. In the use of borax and sodium chlorate in combination for soil sterilization the antagonism in their action can be reduced to a minimum by using the lowest effective dosage of chlorate and adding enough borax to complete the destruction of the vegetation. The borax-chlorate combination for soil sterilization has the advantage of being practically nonpoisonous, and the use of the borax, besides reducing the fire hazard of the chlorate to a low level, provides a residual effect that lowers the probability of reinfestation by seedlings."

Some effects of thallium sulfate upon soils, A. S. CRAFTS (*Hilgardia* [*California Sta.*], 10 (1936), No. 10, pp. 375-398, fig. 1).—Experiments indicate that thallium sulfate is very toxic in soils. Toxicity decreases, however, with time and cropping, and varies with soil type, a range of three times or more having been shown in the soils studied. The toxicity is greater in soils low in fertility, but cannot be correlated with the soil type nor with water-holding capacity.

"Thallium sulfate was strongly fixed in four soils. The saturation capacity of Yolo clay loam for this chemical was about 10,000 p. p. m. on a dry-weight basis. Leaching with as much as 200 cm of distilled water had practically no effect upon the thallium toxicity in these soils.

"Thallium-treated barley, as commonly used for squirrel bait, had little or no effect upon germination or growth of oats planted in the same can and spaced within 0.5 cm of the grains. Growth was reduced when the spacing was 0.25 cm. Thallium-treated whole barley gave a 50 percent germination, and the fresh weight of the seedlings at 30 days was 47 percent of that of the checks. Oat seedlings were unaffected by the application of treated barley to the soil, followed by irrigation, except where the dose was excessive. Thallium-treated barley also had little effect upon growing plants in a pasture area. The heaviest application, equivalent to over 2,500 lb. of grain to the acre, reduced the growth less than 50 percent. . . .

"About 30 lb. of thallium sulfate uniformly distributed would be required to sterilize an acre-inch of soil. Under natural conditions of application it would probably be tied up in a much shallower layer of soil. At least 5,000 lb. of squirrel bait, carrying 1 percent of Tl_2SO_4 uniformly distributed, would be necessary to sterilize an acre completely. . . . In actual field practice, dosage seldom exceeds 1 lb. of thallium-treated grain per acre, bearing 0.01 lb. of Tl_2SO_4 . Dosage rapidly decreases as the rodents are brought under control. The differences between these rates of dosage and those mentioned above show that little need be feared from the sterilization of soils by thallium-treated squirrel bait."

AGRICULTURAL BOTANY

The soil-block washing method in quantitative root study, T. K. PAVLYCHENKO (*Canad. Jour. Res.*, 15 (1937), No. 2, Sect. C, pp. 33-57, figs. 10).—"It has been observed consistently that competition among plants first takes place between the root systems, and that the nature, vigor, extent, and distribution of the root systems have an important bearing on the development of top growth. A new technic for root studies, the soil-block washing method, is described in considerable detail. This method enables the investigator to procure entire root systems at any stage of plant development from plants grown under natural soil conditions."

Frost-hardening studies with living cells, I, II, J. LEVITT and G. W. SCARFF (*Canad. Jour. Res.*, 14 (1936), No. 7, Sect. C, pp. 267-284, figs. 3; No. 8, Sect. C, pp. 285-305, figs. 4).—The following two papers are included:

I. *Osmotic and bound water changes in relation to frost resistance and the seasonal cycle.*—"The osmotic pressure and nonsolvent space of the cells of various types of plant were estimated by the plasmolytic method and related to frost resistance and the seasonal cycle. Osmotic pressure always rises with hardening and falls with dehardening, and it generally reaches higher values or begins to rise earlier in the hardier species and varieties. The effect of osmotic pressure in reducing the amount of ice formation is enhanced in woody plants by the condition that only about half the cell volume is occupied by the osmotically active solution. The remainder, i. e., the nonsolvent space, is shown to consist partly of bound water and must therefore represent hydrophilic colloid. This occupies an even larger proportion of the sap vacuole than of the protoplasm, and it increases notably with hardening. This change, besides reducing intercellular ice, is regarded as protecting the most vulnerable part of the cell, viz, the vacuole, from being frozen at very low temperatures."

II. *Permeability in relation to frost resistance and the seasonal cycle.*—"Cell permeability as estimated by the plasmolytic method in various types of plants and for different classes of solute has been studied in relation to frost resistance and the seasonal cycle. Permeability is found to increase greatly with hardening, whether induced by low temperature or other conditions, and it seems to parallel closely the seasonal changes in frost resistance. As regards different species and varieties, cell permeability in the hardened state shows better correlation than any other character with ability to resist frost. The permeability change is greatest toward potassium nitrate—at least in cells (viz, those of hardy woody plants) that are definitely permeable to the salt; the change is more moderate toward polar nonelectrolytes with small molecules, such as urea, but with these it occurs in all plants capable of hardening; toward apolar substances, such as urethane, there is no change. These relations point to a widening of the aqueous pores or increased hydration of the plasma membrane as the mechanism of the permeability increase. Hypotheses are put forward as to the means by which freer permeability to water may increase resistance to certain types of mechanical injury by frost."

The frost-hardening mechanism of plant cells, [III], G. W. SCARTH and J. LEVITT (*Plant Physiol.*, 12 (1937), No. 1, pp. 51-78, figs. 3).—Continuing this series of studies, the linked series of changes associated with hardness as described are summarized as follows:

"Complicated hydrolytic breakdown of carbohydrates increases the osmotic pressure of the cell and also in the hardier plants and nonsolvent space in the vacuole at the expense of starch and perhaps of other reserves held in the cytoplasm. Due to similar changes in the protoplasmic colloids, the whole cytoplasm, probably, and the plasmic membranes almost certainly, become more hydrated. As a consequence of this change, the viscosity of the protoplasm is lowered. Because of the change in the membranes in particular, cell permeability is increased. If all of these changes are causally connected one with another, the correlation of each and all of them with frost resistance would be found, though only one might play a part in it."

The authors present theories as to the possible role of each but feel that a satisfactory demonstration requires more knowledge of the mechanisms both of injury and of resistance than is yet available.

A bibliography of 48 references is given.

Ontogeny and structure of collenchyma and of vascular tissues in celery petioles, K. ESAU (*Hilgardia [California Sta.]*, 10 (1936), No. 11, pp. 429-476, pls. 8, figs. 8).—Celery petioles were found to contain a semicircle of large collateral vascular bundles on the abaxial and a row of very small bundles on the adaxial side. A subepidermal collenchyma strand occurs in the rib opposite each major vascular bundle on the abaxial side. The collenchyma and the large vascular bundles make up the "celery strings." The petiole of a primordial leaf contains the protoderm, procambium, and ground meristem, and the development of these meristems is described in detail.

The vascular bundles usually contain only primary tissues, although the cambium differentiates the xylem from the phloem in old leaves. The protoxylem is endarch and is made up of spiral vessels and parenchyma. The metaxylem vessels have scalariform and reticular thickenings. No fibers occur in the xylem. The phloem contains sieve tubes, companion cells, and phloem-parenchyma cells. Slime bodies occur in each element of the differentiating sieve tubes, and mature sieve tubes possess no nuclei but contain cytoplasm and plastids. A single sieve plate occurs on the end wall. The sieve tubes and companion cells develop in rapid succession, the old elements being oblit-

erated. Phloem parenchyma cells of the old phloem continue to enlarge for some time and develop thick primary walls constituting, when fully developed, the bundle cap.

When collenchyma is initiated in the ground meristem, the divisions occur in rapid succession, new cells remaining small and closely packed. The wall thickenings appear long before cell elongation ceases. Mature collenchyma cells are prosenchymatous in nature—long, with tapering ends. The collenchyma is mechanically much stronger than the vascular tissue. Its breaking load may be from two to four times that of the entire vascular bundles or the bundle cap.

Vessel development in celery, K. ESAU (*Hilgardia* [California Sta.], 10 (1936), No. 11, pp. 477-488, pls. 4, fig. 1).—"The primary vessels in celery show intact end walls until the elements are almost mature. These walls show a peculiar lenticular thickening in the region that later becomes the perforation. Secondary thickenings are formed on longitudinal walls and usually also on the margins of the end wall around the lenticular thickening, leaving the latter exposed. When the end wall breaks down, the lenticular thickening disappears gradually, as though dissolved. This change occurs after the secondary thickenings have been deposited. The protoplast disintegrates at the same time."

Development of the flower and macrogametophyte of *Allium cepa*, H. A. JONES and S. L. EMSWELLER (*Hilgardia* [California Sta.], 10 (1936), No. 11, pp. 415-428, pls. 4, figs. 5).—"The outer perianth whorl and the outer stamen whorl are the first floral organs to differentiate in the onion. These are followed by the inner perianth whorl and inner stamens, and lastly by the carpels. The outer perianth segments and their subtended anthers usually arise counter-clockwise. The sequence of development of the members of the inner whorls of perianth and anthers is usually clockwise. The first segments of the inner whorls usually arise between the oldest and second oldest segments of the outer whorls. The embryo sac is formed from the chalazal daughter cell. One of the synergids is distinctly hypertrophied; both appear to be well supplied with reserve food."

Hydration studies in fresh and dried red clover roots and shoots with reference to physical properties and chemical composition of tissue, G. A. GREATHOUSE and N. W. STUART (*Plant Physiol.*, 11 (1936), No. 4, pp. 873-880, figs. 3).—"In this study by the University of Maryland, the Ohio and French varieties of red clover were differentiated as to cold hardness by the unfreezable water of the fresh tissue or the rehydration of the dried tissue. The internal factors influencing the hydration capacity appear to differ for root and shoot tissues. The readily available carbohydrates seem to be most important in favoring a greater hydration capacity. The total pectin and total pentosans were not related to the hydration capacity of the root and shoot tissues. The protein nitrogen was usually higher in tissues with lower hydration capacity, and, similarly, the nonprotein nitrogen curves failed to follow the hydration capacity curves. No consistent relation appeared between the total water content of the roots and shoots and the hydration measurements.

The hydration capacity of red clover tissue is influenced by the chemical composition as well as by the organization of living matter.

The dependence of carbon dioxide assimilation in a higher plant on wave length of radiation, W. H. HOOVER (*Smithson. Misc. Collect.*, 95 (1937), No. 21, pp. 13, pls. 3, figs. 4).—"The rate of photosynthesis on the basis of equal incident energy was determined as a function of the wave length of light for a wheat plant. The entire visible spectrum is effective in producing photosynthesis. The wave length limits, although not accurately determined, appear to be

between 7,200 a. u. and 7,500 a. u. on the red end, and less than 3,650 a. u. on the blue end of the spectrum. A principal maximum occurs at 6,550 a. u. in the red, and a secondary one at 4,400 a. u. in the blue. Increased reflection and transmission of radiation in the green region by plant leaves diminish the effectiveness of incident green rays to promote photosynthesis."

Photoperiodic response of certain long and short day plants to filtered radiation applied as a supplement to daylight, R. B. WITKROW and J. P. BREBEL (*Plant Physiol.*, 11 (1936), No. 4, pp. 807-819, figs. 10).—This contribution from the Indiana Experiment Station reports the results of a study of the effects of three bands of radiation, used to prolong normal winter days to 18 hr., on the photoperiodic responses of three long-day plants (*Callistephus chinensis*, *Helianthus cucumerifolius*, and *Scabiosa atropurpurea*), and three short-day plants (*Salvia splendens*, *Cosmos bipinnatus*, and *Tithonia speciosa*). The wave bands included red (650-1,400 m μ), green (455-550 m μ), and blue (380-510 m μ). The results and conclusions are given in detail.

The long-day plants bloomed early under days prolonged with red and white radiation. Aster, seeded in winter, produced higher dry weights (tops and total) under the red. The blue induced earlier flowering in aster and sunflower, but not in *Scabiosa*. Aster and sunflower failed to flower as quickly under green and control conditions as under the red. *Scabiosa* had not bloomed under the blue, green, or control conditions by late spring. The three short-day plants remained in the vegetative condition when the days were lengthened by red and white radiation, but flowered in short days and days lengthened by blue and green light. Red light caused a decrease in synthesized dry matter.

Aster, seeded in the fall (12½-hr. day), failed to respond reproductively when the days were lengthened as designated, and the plants in all the plats bloomed about the same time. When germinated in a shorter day (9½ hr.), the response was as indicated above. *Salvia* from clonal cuttings, with all plants in flower when placed under days lengthened by wave bands as indicated, reverted to the vegetative state under red and white light but remained in the flowering condition under the other treatments. Corn, producing carpellate flowers in the tassel under short days, was prevented from producing such inflorescences by the red and white light used to prolong the day, but not by the blue or green.

It is concluded that, under the conditions imposed, red radiation is most effective in producing the photoperiodic response, both in short- and long-day plants; that some especially sensitive plants (e. g., aster) respond to the blue light; and that green radiation has little effect when used to prolong the day.

Effect of light on solanine synthesis in the potato tuber, H. W. CONNIE (*Plant Physiol.*, 12 (1937), No. 1, pp. 79-98, figs. 6).—"A new analytical method has been developed for the quantitative estimation of solanine in the presence of solanidine, based upon the amounts of sugars set free on acid hydrolysis. Upon irradiation by a mercury arc in Uviol or by Mazda lamps, potato tubers increased in solanine. This was accompanied by the appearance of anthocyanin in the sprouts. Wave lengths which are efficient for glucose synthesis did not induce a significant increase in solanine, but did result in an increase of chlorophyll. Ultraviolet rays of about 0.3 μ are effective for solanine formation but not for chlorophyll elaboration."

The bibliography contains 51 references.

The quantitative mineral nutrient requirements of plants, P. MACY (*Plant Physiol.*, 11 (1936), No. 4, pp. 749-764, figs. 5).—Based on a review of the literature and on the author's experiments with barley, "a theory of the relation-

ship between the sufficiency of a nutrient and its percentage content in the plant is proposed as a measure of the quantitative mineral nutrient requirements of plants. The central concept is a critical percentage of each nutrient in each kind of plant, above which there is luxury consumption, and below which there is poverty adjustment, which is almost proportional to the deficiency until a minimum percentage is reached. . . . It is proposed that the critical nutrient composition of a plant is an 'ideal' but inherent characteristic of the plant, the critical and minimum percentages varying only under special conditions. The critical percentages are believed to be intimately connected with the relationship between vegetation and reproduction. It is shown that the Mitscherlich law of the minimum holds only during poverty adjustment, while the Liebig law of the minimum holds over the rest of the yield curve.

"It is proposed that the use of the theory to determine fertilizer needs of particular crops on particular soils under the particular local conditions may meet the need for a convenient method as reliable as field plat tests."

Effects of phosphorus and lime in reducing aluminum toxicity of acid soils, K. E. WRIGHT (*Plant Physiol.*, 12 (1937), No. 1, pp. 173-181).—In preliminary tests with beets at the Rhode Island Experiment Station, it was found that by the use of calcium lactate the role of calcium as an essential element could be compared with its role in reducing acidity. Healthy, vigorous plants were obtained with lime and superphosphate and very poor plants in untreated acid soil, while those with calcium lactate were intermediate in development between the two extremes. Analyses of these plants indicated that (1) pH, as such, was not a limiting factor, (2) calcium deficiency or (3) photosynthesis could not be considered limiting growth factors, while (4) deficiencies in total nitrogen, nitrates, and phosphorus in the plants from the acid soil revealed possible causes of the retarded growth therein. Further tests, using drip cultures, indicated phosphorus deficiency to be the possible cause of retarded growth, and aluminum as the probable cause of this deficiency. A drip culture method was developed whereby the plants could have access to both aluminum and phosphorus, while at the same time aluminum precipitation in the culture solution could be avoided. Analyses of the plants from each culture series in these tests indicated that (1) damage to the plant as a whole probably resulted from the poor root system induced by the presence of aluminum; (2) aluminum was precipitated immediately in that half of the root system in direct contact with aluminum, whereas the other half of the root system not in contact with aluminum, and the tops, grew practically as well as the control plants; and (3) in the series where each half of the root system was in a culture solution containing both aluminum and phosphorus, internal precipitation evidently played an important role in retarding growth, since, if the precipitation were external, the fairly large amounts of aluminum and phosphorus inside the roots of these plants could not be satisfactorily explained.

It is believed that most workers have overemphasized the external mutual precipitation of aluminum and phosphorus and have overlooked the fact that the internal precipitation of phosphorus by aluminum evidently plays an important role in the poor development of certain plants grown in acid soil. The corrective effect of large applications of superphosphate to such soils is attributed largely to the internal precipitation of aluminum by phosphorus, with sufficient phosphorus remaining for the metabolic processes of the plant.

Effect of boron deficiency upon the structure of *Zea mays*, H. T. ELLINGER (*Plant Physiol.*, 11 (1936), No. 4, pp. 765-778, figs. 9).—In the cultures studied, the first visible effects of boron deficiency appeared on the seventh day as a chlorosis between the veins of the older leaves and failure of the youngest

leaves to unroll normally (due apparently to a colorless jelly). Later formed leaves in some cases broke through and developed partially. From the seventh day the roots exhibited enlarged, cheesy tips, and secondary root primordia developed very close to the root cap. The dry weight of affected plants was higher. A disintegration of parenchyma cells appeared at 4-5 days, accompanied by a filling of some of the air spaces with material staining like the jelly on the leaves. Later there were parts where the entire cross section of the leaf collapsed into a thin band staining red with safranin. In other places the cells had failed to differentiate, and in still others the cells were hypertrophied. Some leaves were thickened, in some cases apparently due to cell enlargement and in others to additional cell layers. At the end of 2 weeks, disintegrating cells occurred in the tip of the stem, and by the end of 3 weeks these areas had enlarged and become especially noticeable where secondary shoot primordia were developing.

The time required for the appearance of the deficiency symptoms seemed to depend on the length of time the plants had been in the boron-deficient solution rather than on their age or previous treatment.

GENETICS

Cytogenetic studies in *Triticum monococcum* L. and *T. aegilopoides* Bal., L. SMITH (*Missouri Sta. Res. Bul.* 248 (1936), pp. 38, figs. 32).—Most plant characters of the varieties of wild einkorn, *T. aegilopoides*, have been dominant over those of varieties of the cultivated form, *T. monococcum*. Genic differentiation in these species has been accompanied by few or minor rearrangements in structure of the chromosomes.

The five inter- and intraspecific hybrids, studied in cooperation with the U. S. Department of Agriculture and involving *T. aegilopoides baidaricum*, had a ring of four chromosomes plus five pairs at diakinesis and first metaphase. *T. monococcum flavescens* × *T. aegilopoides stramineonigrum*, had seven pairs and no ring at meiosis. Hence, the ring-forming complex seems not to be a specific characteristic. Intraspecific hybrids in *T. monococcum* involving three varieties had seven pairs and no ring at meiosis. The ring was transmitted to about one-half of the F_1 and three-fifths of the backcross progeny. Ring-forming F_1 plants heterozygous for a factor for green base seedlings segregated a high proportion of the recessive. In F_1 and F_2 the factor affecting the green base ratio was occasionally present in normal plants and absent in ring-forming plants, indicating that the green base factor and a factor modifying its transmission are linked and associated with one of the ring-forming chromosomes. Most F_2 ring-forming plants produced pollen indistinguishable from that of normal sibs. Seed production of F_2 ring-forming plants was 75 percent of that of normal sibs (65 percent perfect). Fourteen of 17 cases of induced chromosomal rings found proved to have complete ovule fertility. The pollen of 6 examined was normal in appearance.

Of the three types of dissociation of homologous chromosomes at meiosis observed in individuals of the F_1 and F_2 of interspecific crosses involving *T. aegilopoides baidaricum*, one type apparently was determined by supplementary recessive genes, one coming from varieties of *T. monococcum* and one from *T. aegilopoides baidaricum*. Two other types found only in occasional plants appeared to be related genetically to the first type. Two of several cases of induced sterility found were examined cytologically and found to result from disturbances of the meiotic process.

Thirty haploids in *T. monococcum* were observed incidentally in these studies, 9 occurring in the progeny of one plant. Forty-eight genetic characters, includ-

ing 42 induced mutants, are described. Two induced early maturing types make possible the growing of at least 3 crops per year. F_2 and backcross data from 21 crosses involving induced and naturally occurring mutants are presented.

Satellites were found on two of the seven pairs of chromosomes in *T. monococcum*. Their presence, together with the known differences in total length, relative arm length, and position of secondary constrictions, is held to make possible the identification of individual chromosomes.

Crossing over in tomatoes trisomic for the "A" or first chromosome, J. W. LESLEY (*Genetics*, 22 (1937), No. 2, pp. 297-306).—This is a further contribution (E. S. R., 74, p. 180) to genetic studies with the tomato conducted by the California Experiment Station, Riverside.

Inheritance of certain fruit and seed characters in watermelons, D. R. PORTER (*Hilgardia [California Sta.]*, 10 (1937), No. 12, pp. 489-509, figs. 8).—Using as parents varieties which had been inbred for several generations to insure homozygosity, it was found that in the crosses studied red flesh is dominant over yellow, black seed color over white and also over tan, and that yellowish-white skin color in the Snowball variety is recessive to dark green in Angeleno and California Klondike, dominance in all cases being apparently on a single-factor basis. In crossing California Klondike dark green with Thurmond Gray yellowish green, the F_1 color indicated incomplete dominance favoring the darker parent. The segregation of color taking place in backcrosses of the seedlings with both parents suggested that single-factor differences governed segregation. Skin stripedness of Golden Honey was incompletely dominant to dark-green skin of California Klondike. Rind toughness of Golden Honey and Thurmond Gray was dominant to tenderness in California Klondike, the segregation in the F_2 indicating a single-factor difference.

No evidence of linkage was observed between (1) color of flesh and seed coat, (2) flesh and fruit-skin colors, (3) flesh color and rind toughness, (4) fruit-skin color and rind toughness, (5) seed-coat color and rind toughness, and (6) skin color with seed-coat color.

Virus mutation and the gene concept, H. H. MCKINNEY (*Jour. Heredity*, 28 (1937), No. 2, pp. 51-57, figs. 3).—From a critical review of previous work, including his own and with particular reference to the mosaic group, the author believes that the available evidence tends to favor the view that the virus and its mutants embrace the essential elements of lineage or inheritance. This view is based on the evidence that the virus and its mutants and submutants regenerate true to measurable types, and that the mutants and submutants tend to retain certain characteristics of the primary virus and the submutants to retain certain characteristics of the strains from which they were derived. It would appear that these combined features, rather than Mendelian segregation, must serve as the basic test for inheritance, otherwise the stand would be taken that inheritance does not exist in asexual organisms. In any case, the primary virus and its mutants are believed to reflect a series of closely related compounds which function essentially as genes. The several characteristics of a given virus may reflect properties of a single compound, and changes in any of these characteristics—mutations—may reflect alterations in this compound.

Heredity of cryptorchidism in sheep, [I], II, Ā. L. GLEMBOTSKIĬ (J. Z. GLEMBOTSKIĬ) and S. B. MOISEEV (*Vsesoiuzn. Inst. Zhivotn. [Moskva]*, *Uspekhi Zootekh. Nauk (All-Union Sci. Inst. Anim. Husband., Adv. Zootech. Sci.)*, 1 (1935), No. 1, pp. 5-28, figs. 5; *Eng. abs.*, pp. 27, 28; 3 (1936), No. 1, pp. 5-50, figs. 21; *Eng. abs.*, p. 50).—The occurrence of from 10 to 15 percent cryptorchid rams, most of which were bilateral, in the Wallachian and Precoces breeds was attributed to the operation of a single pair of recessive genes. The cryptorchid

condition was associated with hornlessness, as all the polled Precoces rams were heterozygotes or cryptorchids. It is suggested that eventually the use of polled rams may result in 25 percent of the males born being cryptorchids.

In the second article, further experimental data confirmed the relation between hornlessness and cryptorchidism in Precoces sheep. All of 312 dicryptorchids were polled. Variations in the number of cryptorchid progeny were related to the polled or horned condition of the rams and ewes. Some irregularities observed, such as horned cryptorchids, needed further investigation. A semilethal condition designated as bend of the neck was, in most cases, associated with cryptorchidism. Dicryptorchids weighed 6 to 8 percent less at one year of age than normal rams, but wool production did not differ.

Studies of multiple allelomorph series in the house-mouse, I, II (*Jour. Genet.*, 33 (1936), No. 3, pp. 443-453; 34 (1937), No. 1, pp. 1-18, figs. 2).—Two parts of this series are noted.

I. *Description of agouti and albino series of allelomorphs*, L. C. Dunn.—Study is reported of the effects of the genes in the albino series C , c^{ch} , c^h , and c^a on black and yellow pigmentation in the agouti series A^+ , A^L , A , a^+ , and a in the mouse. The alleles to C dilute both black and yellow but yellow is more affected than black, being entirely suppressed by c^h and c^a . Black is little affected by c^{ch} , considerably diluted by c^h , and suppressed only by c^a . Brown was even less affected by these genes than black. In combination with the pink-eye factor, c^h and p act in a cumulative manner and cause greater dilution of black than either one alone. One individual combining c^{ch} with the blue dilution factor d was light blue in the black parts and lighter than individuals with either c^{ch} or d alone.

II. *Methods for the quantitative estimation of melanin*, W. Einsele.—A method is presented for isolating and studying the melanin pigment in the hairs of mice of different genotypes as to the percentage of melanin present, the intensity of the color, and the size of the granules.

Abortive differentiation of the ear vesicles following a hereditary brain-anomaly in the "short-tailed waltzing mice", K. BONNEVIE (*Genetica* [s. Gravenhage], 18 (1936), No. 5-6, pp. 105-125, pls. 3, figs. 12).—A comparative study of the ear vesicles of normal and "shaker-short" embryos¹ of a strain of short-tailed waltzing mice shows on the ninth day of embryonic development an abortive differentiation of the shape of the ear vesicles dependent on the brain anomalies of the "shaker-short" strain. Morphological variations from normal in the ear vesicles of these mice are described.

Hairless rats found to have a shortened life cycle (*Illinois Sta. Rpt.* 1935, pp. 114, 115).—Hairlessness in the rat was found by E. Roberts and J. H. Quisenberry to be inherited independently of the genes for albinism, nonagouti, spotting, dilution, and red eye. The duration of life of hairless rats was shortened as contrasted with normals.

Genogeography of the domestic fowl, A. S. SEREBROVSKIĬ (SEREBROVSKY) (*Vsesoiuzn. Inst. Zhivotn. [Moskva], Uspekhi Zootekh. Nauk (All-Union Sci. Inst. Anim. Husband., Adv. Zootech. Sci.)*, 1 (1935), No. 1, pp. 85-142, figs. 17; *Eng. abs.*, pp. 141, 142).—An account of the genes carried by the fowls native to different regions of the Balkans.

Relative growth and hereditary size limitation in the domestic fowl, I. M. LERNER (*Hilgardia [California Sta.]*, 10 (1937), No. 13, pp. 511-560, figs. 3).—Studies of the heterogonic growth relations in Plymouth Rock and Minorca fowls indicated that the growth of the pectoralis major in relation to body weight and the leg bones follows a similar course in the two breeds, and that

¹ *Acta Path. et Microbiol. Scand.*, Sup. 26 (1936), pp. 20-26, figs. 2.

their hybrids possess the same pattern of growth. Studies of other breeds of fowls also confirmed this. It thus appears that a basic genetic complex for size interrelation of parts exists in the fowl, which does not necessarily have a bearing on the ultimate size. Different relations were evident in Bantams, where hypogony was present in the leg bones, as indicated by the value of the constant k being less than unity in the equation $y = bx^k$. It is suggested that Bantams possess growth-retarding factors affecting not only total body size but also the relative rate of growth of the parts.

Further data on genetic modification of rumplessness in the fowl, L. C. DUNN and W. LANDAUER (*Jour. Genet.*, 33 (1936), No. 3, pp. 401-405).—Further studies of the genetics of rumplessness in the fowl at the [Connecticut] Storrs Experiment Station have demonstrated the presence of multiple and recessive modifiers toward the normal of the rumpless condition in both heterozygotes and homozygotes. These may in some cases extinguish all external character differences between heterozygotes and normals, a condition discovered only on dissection.

The physiology of cold blackening in Russian rabbits.—II, The influence of Röntgen rays on pigment formation [trans. title], R. DANNEEL and E. LUBNOW (*Biol. Zentbl.*, 56 (1936), No. 11-12, pp. 572-584, figs. 3).—Continuing this series (*E. S. R.*, 76, p. 24), treatment with Röntgen rays of portions of the skin of black Alaska rabbits from which the hair had been plucked caused the newly developing hair to come in lighter in color, and with heavier radiation it was white. Röntgen rays had the same effect on newly developing hair in the Russian rabbit as was produced by cold. It is suggested that the irradiation rendered the mitochondria of the hair-building cells nonfunctional and prevented normal pigment formation.

On the mating periods of the mare, V. A. SHCHEKIN (*Prob. Zhivotn. (Prob. Anim. Husb.)*, No. 8 (1936), pp. 14-27; *Eng. abs.*, p. 27).—General directions for handling the breeding mare during the mating season are presented, with special reference to mares with long heat periods. Best results are obtained in normal heat periods with matings 3 to 4 days before the end of heat.

Oestrus and ovulation in the mare, L. M. MIRSKAYA (MIRSKAYA) and A. A. ZALTSMAN (SALZMAN) (*Vsesoiuzn. Inst. Zhivotn. [Moskva], Uspekhi Zootekh. Nauk (All-Union Sci. Inst. Anim. Husb., Adv. Zootech. Sci.)*, 1 (1935), No. 1, pp. 157-168, figs. 2; *Eng. abs.*, p. 168).—A study of the vaginal smear of 45 mares showed that during oestrus the smear consisted only of cornified epithelial cells, and the mucous membrane is hyperemic and moist with the cervix relaxed. Based on data from 53 mares, the duration of oestrus ranged from 2 to 11 days, averaging 5.65 days. The range depends upon the rate of growth of the follicle but ovulation occurred from one to two or rarely three days before mating desire ceased. The size of the follicles at the same stage of maturity was variable, but the threshold for expressing mating desire based on reaction to the stallion was related to the size of the follicle on the first day of the heat period.

Vaginal method of pregnancy diagnosis in the mare, K. BARULIN (C. BAROULIN), E. BURCHENKO (BOURCHENKO), and A. POPOV (*Prob. Zhivotn. (Prob. Anim. Husb.)*, No. 8 (1936), pp. 42-53; *Eng. abs.*, p. 53).—Results are presented with pregnancy tests based on the appearance of thick, turbid, and clammy mucous in the vagina of pregnant mares. About 50 percent of the mares showed positive test during the second 10-day period after mating, whereas the majority of the pregnant mares gave positive tests between 40 and 60 days after conception. Pregnant animals showed the presence of mucous balls not evident in nonpregnant mares.

Sex physiology of sheep, L. L. ROUX (*Onderstepoort Jour. Vet. Sci. and Anim. Indus*, 6 (1936), No. 2, pp. 465-717, figs. 43).—This report comprehensively reviews the literature and presents results of extensive experimentation on the influence of nutrition upon the sexual activity of Merino ewes; the morphology of the ovaries of Merino sheep during anoestrus; the duration of the phases of the dioestrous cycle in Merino sheep; the period of the absence of oestrus after parturition in Merino sheep; the sexual season of cross-bred sheep; the age of puberty of Merino and cross-bred sheep; the influence of climate upon the sexual activity of young Merino ewes; the effects of inoculation, shearing, and dipping upon sexual activity; and the artificial induction of oestrus during anoestrus. The report is concluded with a discussion of certain principles of sex physiology in relation to practical sheep husbandry.

Studies on the physiology of reproduction in the sheep.—IV, Fetal development, L. M. WINTERS and G. FEUFFEL (*Minnesota Sta. Tech. Bul.* 118 (1936), pp. 20, figs. 12).—Continuing this series of studies (*E. S. R.*, 75, p. 469), data are reported on the weights and measurements of 73 fetuses from 46 ewes killed at different stages of the gestation period, ranging from 34 to 140 days. The ewes prior to the test were divided into three groups, one being larger than the rest, and of the other two groups, one was placed on a higher and the other a lower plane of nutrition. The results showed no difference in the rate of fetal development in the fetuses of the ewes in the different groups. Single lambs were slightly larger than twins after the seventieth day of the gestation period. Four corpora lutea were observed which on macroscopic examination appeared single but on microscopic examination were found to contain two fused corpora lutea.

Artificial insemination of she-goats, V. V. POLOVTSEVA and M. V. FOMENKO (*Vsesoiuzn. Inst. Zhivotn. [Moskva], Uspekhi Zootekh. Nauk (All-Union Sci. Inst. Anim. Husband., Adv. Zootech. Sci.)*, 3 (1936), No. 1, pp. 51-65, figs. 6; *Eng. abs.*, p. 65).—Artificial insemination was successfully carried out with 650 does. Doses of 0.025 to 0.05 cc of semen were as successful as doses of 0.1 to 0.2 cc, producing about 90 percent fertility. The sexual cycle of the goat ranged from 12 to 24 days, averaging 19.42 ± 0.49 day, with the duration of oestrus ranging from 1 to 4 days and averaging 39.16 ± 1.9 hr. Fertility decreased toward the end of the breeding season. The duration of all gestations averaged 148.8 ± 0.09 days, with twins being about one day shorter than singles. Aged does were more fertile than those bred at 1 and 2 yr. of age. Angora goats showed a stronger sexual activity than milk goats. Of the kids produced 47.8 percent were males and 52.2 percent were females.

The production and changes in the endometrium of swine in relation to the function of the uterus [trans. title], B. P. KHVATOV (CHWATOW) and N. N. KUZNETSOV (KUSNEZOW) (*Vsesoiuzn. Inst. Zhivotn. [Moskva], Uspekhi Zootekh. Nauk (All-Union Sci. Inst. Anim. Husband., Adv. Zootech. Sci.)*, 1 (1935), No. 1, pp. 169-175, figs. 2; *Ger. abs.*, p. 175).—Histological study was made of the mucous membrane of the uteri of parous and nonparous sows. After 5 to 6 days, prolan injections in young gilts were found to produce changes in the uterus and broad ligament similar to those occurring during pregnancy.

The germ cell cycle in the guinea pig, I, II, C. G. BOOKHOUT (*Ztschr. Zellforsch. u. Mikros. Anat.*, 25 (1937), No. 5, pp. 728-748, figs. 15; pp. 749-763, figs. 14).—Two papers are presented in this series. In the first, The Embryonic Development of the Testis, a description is given of the primordial germ cells in timed guinea pig fetuses and the subsequent changes evident during growth of the testicle up until the time of parturition. In the second, The Postnatal Development of the Testis, a description is continued of the postnatal development until the time of sexual maturity.

Studies on the physiology of lactation.—III, The reciprocal hypophyseal-ovarian relationship as a factor in the control of lactation, W. O. NELSON (*Endocrinology*, 18 (1934), No. 1, pp. 33-46, figs. 2).—Continuing the series previously noted (E. S. R., 75, p. 614), study of the influence of the administration of the lactogenic hormone and removal of gonads or uteri during pregnancy in guinea pigs led to the conclusion that the ovarian hormones are active in promoting mammary gland growth during gestation and that they also inhibit the secretion of the lactation-inducing hormone of the pituitary until after parturition.

Studies on the physiology of lactation, IV, V (*Anat. Rec.*, 60 (1934), No. 1, pp. 69-76; 66 (1936), No. 2, pp. 201-215, figs. 14).—Two papers in this series (above noted) are presented.

IV. *The assay of the lactogenic hormone of the anterior hypophysis*, W. O. Nelson.—The merits of various methods of assaying the lactogenic hormone of the hypophysis are discussed. The female guinea pig, hysterectomized at 40 to 50 days of gestation, and the pseudopregnant rabbit provide test animals in which the mammary glands are prepared for normal lactation. Except for not depending on a milk secretion response, the crop gland test in the pigeon is quantitative and has certain advantages.

V. *The induction of lactation in depancreatized dogs*, W. O. Nelson, H. E. Himwich, and J. P. Fazekas.—Lactation was initiated in five of nine bitches by the administration of lactogenic hormone. An adequate proliferation of the mammary gland prior to treatment with the lactogenic hormone was essential if lactation was to be induced.

On the physiology of lactation, M. SKARZHINSKAÏA (SKARZHINSKAYA) (*Vsesoiuzn. Inst. Zhivotn. [Moskva], Uspekhi Zootekh. Nauk (All-Union Sci. Inst. Anim. Husb., Adv. Zootech. Sci.)*, 3 (1936), No. 1, pp. 67-78; *Eng. abs.*, p. 78).—Injections of pituitary extracts into cows during the second to fourth months of lactation and in the first half of gestation caused an increase in milk production without subsequent injurious effects on the cow or on subsequent production. Prolactin did not increase production.

On the physiology of lactation, G. I. AZIMOV and N. K. KRUIZE (*Vsesoiuzn. Inst. Zhivotn. [Moskva], Uspekhi Zootekh. Nauk (All-Union Sci. Inst. Anim. Husb., Adv. Zootech. Sci.)*, 3 (1936), No. 1, pp. 79-111; *Eng. abs.* pp. 110, 111).—Lactogenic extracts of the anterior pituitary caused a 15 percent increase in the milk production without later depression in production in cows.

Effect of thyroxine and galactin on lactation in hypophysectomized guinea pigs, E. T. GOMEZ and C. W. TURNER (*Soc. Expt. Biol. and Med. Proc.*, 36 (1937), No. 1, pp. 80, 81).—Continuing these studies at the Missouri Experiment Station (E. S. R., 76, p. 465), the authors were unable to prevent the rapid cessation of milk production which follows hypophysectomy in lactating animals by the administration of thyroxine in addition to galactin. Attention, however, was called to the increases and decreases in milk production which follow thyroxine administration or thyroidectomy, respectively, in normal animals.

Lactogenic preparation from anterior pituitary, G. I. AZIMOV, M. N. LAPINER, M. I. SKARZHINSKAÏA (SKARGINSKAÏA), N. P. PARIŠKAÏA, and A. V. KORSAKOVA (*Vsesoiuzn. Inst. Zhivotn. [Moskva], Uspekhi Zootekh. Nauk (All-Union Sci. Inst. Anim. Husb., Adv. Zootech. Sci.)*, 1 (1935), No. 1, pp. 143-156; *Eng. abs.*, p. 156).—Acid and alkaline extracts of the anterior pituitary were tested on rabbits, dogs, guinea pigs, dairy cows, sows, and pigeons as to their lactogenic effects. Differences in the response were noted.

Practical application of lactogenic hypophysis preparations, G. I. AZIMOV, N. KRUIZE (KROUZE), M. SKARZHINSKAYA (SKARSHINSKAYA), A. MAKHOVA, and O. FOMINSKAYA (FOMINSKAYA) (*Prob. Zhivotn. (Prob. Anim. Husb.)*, No. 8 (1936), pp. 28-41, figs. 5; *Eng. abs.*, p. 41).—Increases in the milk yield were produced by injections of lactogenic hormones consisting of extracts of the entire anterior pituitary. The injections were harmless and had no undesirable aftereffects. The best results were obtained during the first half of the lactation period.

Effect of lactogenic hormone injections on the crop gland of the hypophysectomized pigeon, E. T. GOMEZ and C. W. TURNER (*Soc. Expt. Biol. and Med. Proc.*, 35 (1936), No. 1, p. 59).—In studies at the Missouri Experiment Station, prolactin was incapable of causing crop gland proliferation in hypophysectomized pigeons.

Inability of sheep to develop antihormone to the gonadotropic hormone from sheep-pituitary glands, K. W. THOMPSON (*Soc. Expt. Biol. and Med. Proc.*, 35 (1937), No. 4, pp. 634-637).—Data are reported on the injection of extracts of fresh and dried sheep pituitary into two ewes for six months' periods. The results revealed no evidence of the production of antibodies to the gonadotropic hormones. In experiments with other species, the same sheep pituitary extracts produced antigonadotropic hormones. These results lend support to the conception that antihormones are the product of the reaction of the animal to an antigen.

Inhibition of action of pituitary hormones by animal sera, K. W. THOMPSON and H. CUSHING (*Roy. Soc. [London] Proc., Ser. B.*, 121 (1937), No. 824, pp. 501-517, pl. 1, figs. 4).—The daily administration for 17 mo. of an extract of sheep pituitary to a female collie caused the blood serum of this dog, when injected into rats prior to the 100-hr. test period, to counteract completely the action of the gonadotropic hormones from sheep and hog pituitaries, human menopause and pregnancy urine, and from the serum of pregnant mares. The action of gonadotropic hormones from sheep and hog pituitaries, human pregnancy urine, and pregnant mare serum was partially checked by dog serum rendered antagonistic by 4-mo. daily injections with gonadotropic extract of pregnant mare serum.

The augmentary factor in animal sera after injections of pituitary extract, K. W. THOMPSON (*Soc. Expt. Biol. and Med. Proc.*, 35 (1937), No. 4, pp. 640-644, fig. 1).—The blood serum from a mare and two dogs to which were administered extract of sheep pituitary glands was found to augment the effect of the extract on the ovarian weight in rats. This effect is attributed to the presence of an antihormone to the antagonist in the blood serum of the injected dogs and mare. The augmenting factor was present only in the pseudoglobulin fraction of the serum.

Effect of stimulus of suckling upon galactin content of the rat pituitary, R. P. REDCE and C. W. TURNER (*Soc. Expt. Biol. and Med. Proc.*, 35 (1937), No. 4, pp. 621, 623).—In further studies at the Missouri Experiment Station (see above), the bird units of galactin in the pituitary of post partum rats not suckled for 15 hr. was 9.2 as compared with 5.2 for rats suckled but from which no milk was removed because the primary milk duct was ligated. The amount of galactin per pituitary was still further reduced to 3.06 bird units in animals which were suckled and the milk removed.

Galactin content of the rat pituitary, R. P. REDCE and C. W. TURNER (*Soc. Expt. Biol. and Med. Proc.*, 35 (1936), No. 1, pp. 60-62).—Data are reported from the Missouri Experiment Station on the galactin content of the pituitary glands of normal and castrated male rats and pregnant and post partum females. The results show that the bird units of galactin increase as the

animal matures, largely due to the increased weight of the gland. Where hormones increased or decreased pituitary weight, the galactin content was likewise generally increased or decreased, respectively. Female rats showed the presence of more galactin in their pituitary glands than male rats. At 48 hours post partum the galactin content of the pituitary doubled as compared with the normal, but at 10 days post partum the galactin content of the gland decreased and was midway between the glands of normal females and 48-hr. post partum females.

Hormone production in the undescended testis, F. M. HANES and C. W. HOOKER (*Soc. Expt. Biol. and Med. Proc.*, 35 (1937), No. 4, pp. 549, 550).—Assays of the male hormone in normal and cryptorchid swine testicles showed that there was about twice as much hormone per unit of weight in the normal as in the cryptorchid organs, notwithstanding the hypertrophy of the interstitial cells in such cases.

Physico-chemical indexes of the sperm of domestic animals, A. BERNSTEIN (BERNSTEIN) and N. SHERGIN (Vsesoiūzn. Inst. Zhivotn. [Moskva], Uspekhi Zootekh. Nauk (All-Union Sci. Inst. Anim. Husband., Adv. Zootech. Sci.), 2 (1936), No. 1, pp. 5-18, fig. 1; Eng. abs., pp. 17, 18).—Physicochemical studies dealing especially with the electrical conductivity are reported on the semen of the ram, bull, stallion, buck, boar, man, and drake.

The potassium, sodium, and calcium content in the sperm and secretions of the sexual glands of the boar, T. N. NESMEĬANOVA (Vsesoiūzn. Inst. Zhivotn. [Moskva], Uspekhi Zootekh. Nauk (All-Union Sci. Inst. Anim. Husband., Adv. Zootech. Sci.), 2 (1936), No. 2, pp. 252-266, figs. 4; Eng. abs., pp. 265, 266).—Analysis of the potassium, sodium, and calcium content of the semen, blood serum, and secretions of the epididymis and seminal vesicles of the boar showed that the spermatozoa prior to leaving the epididymis are in surroundings poor in electrolytes, but during ejaculation the surroundings are rich in electrolytes, particularly sodium.

Duration of the vitality of spermatozoa of a bull in epididymis isolated from the testiculæ, V. S. KIRILLOV and V. A. MOROZOV (MOROSOV) (Vsesoiūzn. Inst. Zhivotn. [Moskva], Uspekhi Zootekh. Nauk (All-Union Sci. Inst. Anim. Husband., Adv. Zootech. Sci.), 2 (1936), No. 1, pp. 19-22, fig. 1; Eng. abs., p. 22).—Following ligation of the epididymis of the bull, 70 percent of the spermatozoa were found to retain progressive movement after 37 days and an oscillating movement for more than 2 mo. Sperm were discharged at copulation approximately 3 to 4 mo. after the operation.

The relation of antecedent egg production to the sex ratio in the domestic fowl, M. O. KĖOROSH (HOROSH) (Vsesoiūzn. Inst. Zhivotn. [Moskva], Uspekhi Zootekh. Nauk (All-Union Sci. Inst. Anim. Husband., Adv. Zootech. Sci.) 2 (1936), No. 1, pp. 95-102, fig. 1; Eng. abs., pp. 101, 102).—A study of the sex ratios of chicks produced by nearly 800 hens, in contradiction of data presented by Jull (*E. S. R.*, 52, p. 77), indicated no relation between the sex ratio and the antecedent egg production of the dams.

The hen's egg not fertilized in the ovary, C. G. HARTMAN (Science, 85 (1937), No. 2200, p. 218).—From an analysis of the results of other investigators, including especially those of Warren and Kilpatrick (*E. S. R.*, 63, p. 727), the author concludes that the hen's egg is not fertilized in the ovary.

Hatchability as related to seasons and hour of laying, F. A. HAYS (Poultry Sci., 16 (1937), No. 2, pp. 85-89, figs. 8).—Data are presented on the hatching of eggs laid at different times of the day and at different seasons by hens and pullets over a 20-yr. period at the Massachusetts Experiment Station. The results showed that hatchability increased as the hatching season advanced for

the hens but not for the pullets. Forenoon and afternoon eggs did not differ in fertility, mortality, or hatchability of the fertile eggs.

Light in relation to the experimental modification of the breeding season of turkeys. H. M. SCOTT and L. F. PAYNE (*Poultry Sci.*, 16 (1937), No. 2, pp. 90-96, figs. 2).—Through the use of morning lights from 4:30 a. m. to daylight from December 1 to February 1 at the Kansas Experiment Station, housed turkey hens were induced to begin laying on January 3 at 242 days of age. Similar turkeys not subjected to light with and without housing started laying on March 9 and 10 at 307 and 308 days of age.

In further experiments white and red lights were found to stimulate earlier sexual maturity, although blue light failed to exert any influence. As food consumption varied only slightly during the first part of the experiment, light is considered to be the controlling factor in inducing early maturity. Housing was also found to have no influence on ovarian activity. Where the lighting period coincided with daylight no stimulation was effected. Attempts to hasten sexual maturity in the guinea fowl by light were ineffective.

FIELD CROPS

[Research with field crops in Illinois], W. L. BURLISON, C. A. VAN DOREN, J. C. HACKLEMAN, C. M. WOODWORTH, O. H. SEARS, L. E. ALLISON, J. J. PEEFER, W. P. FLINT, J. H. BIGGER, B. KOEHLER, W. J. MUMM, J. R. HOLBERT, G. H. DUNGAN, A. L. LANG, D. C. WIMER, E. E. DE TURK, E. B. EARLEY, E. W. LEHMANN, R. H. REED, O. T. BONNETT, and H. H. MCKINNEY (*Illinois Sta. Rpt.* 1935, pp. 39-72, figs. 8).—The reports of progress of investigations in field crops included in these pages (E. S. R., 74, p. 477) deal with variety trials with corn (and corn hybrids), winter and spring wheat, oats, barley, buckwheat, grain sorghum, alfalfa, red clover (strains), soybeans, seed flax, and safflower; "fermentation rime" tests with winter wheat strains; breeding work with corn for oil and protein content, length of ear, number of ears, and resistance to *Aspergillus flavus*, and with wheat, oats, and soybeans; improvement of corn by top-crossing and by reconstitution; reduction of losses from ear rots by resistant corn hybrids; relative susceptibility of smooth v. rough kernels of corn to seed coat injury; the inheritance of seed characters in soybeans; cultural (including planting) tests with red clover and other clovers; nurse crop and cutting tests with red clover; studies of the shrinkage of corn and other crops in storage; analyses of yields of varieties of winter wheat with studies of factors contributing to yields of the wheat plant, such as diameter of stem, soil moisture content, and development of the wheat spike; the occurrence of wheat mosaic in different counties and on different varieties; fertility value of cornstalk ash and residues and of straw, and growing soybeans, all for soil improvement; investigation of the nutrition of the corn plant and the development by selection and breeding of desirable nutritional habits; the relation of straw to the feeding power of plants and to the usefulness of the minerals present in the soil; studies of the factors influencing the nodulation of legumes; comparison of types of inoculants; tests of chlorates and other chemicals for poison-ivy, Canada thistle, and quackgrass; life history and control studies with wild garlic and onions; production studies with crops relatively new to Illinois, including pyrethrum, safflower, Russian hemp, flax, buckwheat, and Jerusalem-artichoke; and utilization of soybean oil in paints. Certain activities proceeded in cooperation with the U. S. Department of Agriculture.

[Field crops experiments in Indiana] (*Indiana Sta. Rpt.* 1936, pp. 18-21, 71, 73, fig. 1).—Investigations with field crops again reviewed briefly (E. S. R.,

75, p. 766) included breeding work and seed improvement with wheat; variety trials with oats and soybeans; planting tests with corn, oats, and soybeans; fertilizer experiments with corn, alfalfa, and pasture; manurial value of crop residues from corn, soybeans, and wheat; the need of soybeans for reinoculation; reestablishment of grass cover on eroded land; substitution of alfalfa for part of the clover in seed mixtures; and tests of *Lespedeza sericea* and winter oats.

[Field crops investigations in Tennessee], H. P. OGDEN, N. I. HANCOCK, L. S. MAYER, B. D. DRAIN, L. R. NEEL, B. P. HAZLEWOOD, and L. A. FISTER (*Tennessee Sta. Rpt. 1936*, pp. 8, 9-13, 15-19, 47, 48, 51, 52, 53, 54, 55-57, 59-63, 68, figs. 4).—Field crops research at the station and substations (E. S. R., 76, p. 29) briefly comprised breeding work with corn, cotton, oats, wheat, barley, rye, sweetpotatoes, soybeans, and winter peas; selection of *Lespedeza sericea* for tannin content; variety trials with corn (and comparisons of corn hybrids), cotton, wheat, oats, rye, barley, potatoes, sweetpotatoes, soybeans, lespedeza, and red clover strains; cultural, including planting, experiments with corn, cotton, oats, soybeans, annual lespedeza, and *L. sericea*; seeding of cowpeas in corn as a last cultivation; cutting tests with *L. sericea*; fertilizer experiments with corn, cotton, barley, sorgo, and annual lespedezas; seed treatments and seeding tests with *L. sericea* and crimson clover; experiments on the possibility of producing sugar beet seed in Tennessee; tests of new phosphorus carriers for wheat, lespedeza, and corn; comparison of winter cover crops; pasture experiments; trials of winter crops for pasture; crop rotations; and weed killing with calcium cyanamide. Certain lines of work were in cooperation with the U. S. Department of Agriculture and the Tennessee Valley Authority.

[Agronomic experiments in Washington], E. G. SCHAFER, O. E. BARBER, O. A. VOGEL, E. F. GAINES, R. M. WEHLING, A. M. SCHLEUBER, D. C. SMITH, C. L. VINCENT, L. K. JONES, C. I. SEELY, H. P. SINGLETON, and C. A. LABSON (*Washington Sta. Bul. 342* (1936), pp. 10-14, 44, 57-62, 64, 65).—Field crops research (E. S. R., 75, p. 38), reported on from the station and substations and in some lines in cooperation with the U. S. Department of Agriculture, comprised variety tests with spring and winter wheat, barley, oats, rye, corn, alfalfa, sweetclover, and red clover (strains); breeding work with potatoes and forage grasses; resistance of wheat to physiologic forms of bunt; inheritance and improvement studies with corn, barley, oats, and wheat; cultural (including planting) studies with forage grasses and strawberry clover; storage tests with washed potatoes; permanent fertility and organic matter maintenance studies; fertilizer tests with alfalfa and with potatoes, corn, and wheat in rotation; crop rotations; behavior of wheat, oats, and barley on summer fallow v. pea land; study of competition between alfalfa and sweetclover and cereals and grasses as companion crops; and weed control experiments.

The effect of tillage method, crop sequence, and date of seeding upon the yield and quality of cereals and other crops grown under dry-land conditions in north-central Montana, M. A. BELL (*Montana Sta. Bul. 336* (1937), pp. 123, figs. 25).—Information with supporting data derived from investigations with field crops grown under dry land conditions at the Northern Montana Substation, near Havre, 1916-35, made in cooperation with the U. S. D. A. Bureau of Plant Industry, is summarized, with brief discussions suggesting possibilities of practical application to dry land farming in north-central Montana. The several experiments and studies were concerned with variation in crop yields because of seasonal conditions; the influence of tillage on yields of spring and winter wheat, barley, oats, corn, flax, rye, potatoes,

and sugar beets; other facts about tillage methods, including features of the fallow system, yields on disking after intertilled crops, spring v. fall plowing, and results with fall listing, disked stubble, and other tillage methods, and from spring listing for corn; results from depth of plowing experiments with small grains, for fallow, and stubble land in the spring and fall; results from different methods of preparing fallow as to time of plowing, plowed v. plowless fallow, stubble cultivation before plowing for fallow, and depth of plowing; modification of the alternate fallow and cropping system, including the two crop system, substitution of an intertilled crop for fallow, allowing land to lie idle during fallow period, small grains harvested for hay as a substitute for fallow, and crop rotations for dry land; the influence of corn, flax, barley, oats, and spring wheat as previous crops upon yield, and the effect of continuous cropping; influence of green manures and barnyard manure on succeeding crops; quality of small grains, i. e., test weight and protein, as influenced by tillage method and by other factors, and of size of root crops and sugar content of sugar beets as influenced by tillage; results of date of seeding experiments with spring and winter wheat, oats, barley, spring rye, corn, and flax; crop varieties grown commercially under dry land conditions; the weed problem under dry farming conditions, especially with Russian-thistles, pigweed, mustards, wild oats, and skeletonweed; and the removal of soil moisture by spring wheat and its accumulation in fallowed land, especially in different kinds of fallow.

A digest of pasture research literature in the continental United States and Canada, 1885 to 1935, corrections and additions, February 1937, A. J. PIETERS ([U. S. Dept. Agr., Bur. Plant Indus.], 1937, pp. 12).—Several corrections and 58 additional titles supplement those listed earlier (E. S. R., 75, p. 195).

The influence of rainfall upon tuft area and height growth of three semi-desert range grasses in southern Arizona, P. B. LISTER and F. X. SCHUMACHER (*Jour. Agr. Res. [U. S.]*, 54 (1937), No. 2, pp. 109–121, figs. 4).—Effects of variation in precipitation distribution during a 15-mo. period on the annual density change and height growth of the three forage grasses—three-awn grass (*Aristida* spp.), black grama (*Bouteloua eriopoda*), and Rothrock grama (*B. rothrockii*)—within the growing season of the current year (in the period 1923–32) were determined by statistical analysis. Graphic expressions of the average effect of an added inch of precipitation per month indicated, in the case of the two grama grasses, that the most beneficial precipitation distribution from normal for both density change and height growth consists of relatively dry winters coming between relatively wet autumns and springs. Three-awn grass seemed to be admirably adapted to variation in precipitation distribution characteristic of the area studied in that either positive or negative departure from normal seasonal precipitation benefits, in general, either density change or height growth, although not both at once.

A mixture of alfalfa and smooth brome grass for pasture, H. C. RATHER, C. M. HARRISON, G. A. BROWN, and G. E. TAYLOR (*Michigan Sta. Circ.* 159 (1937), pp. 7, fig. 1).—The mixture of alfalfa and brome grass, according to results of experiments in progress, furnishes productive and drought-resistant pasturage high in palatability and nutrients and valuable not only in summer but throughout the entire grazing season, and is also adapted to a wide range of conditions in Michigan. Cultural and grazing management practices are outlined briefly.

The 1936 Iowa corn yield test, M. M. RHOADES and J. L. ROBINSON (*Iowa Sta. Bul.* 355 (1937), pp. 185–240, fig. 1).—The 879 entries in the 10 harvested districts of the 1936 Iowa Corn Yield Test, conducted cooperatively as in previ-

ous years (E. S. R., 75, p. 41), were again grouped as regular and experimental open-pollinated and regular and experimental hybrids.

The 1930 yield test was featured by the superior performance of hybrid combinations as compared with open-pollinated varieties, the average yield of all hybrid entries in the 10 fields being 30.8 percent greater than for open-pollinated strains. The hybrid entries also had much more lodging resistance. The average percentage increase of the hybrid class in the 4 easternmost fields was as great as in other districts, whereas in past tests hybrid entries tended to perform relatively better in the western and central districts.

Yields and stands obtained by planting seed of different germinating percentages at rates to give the same theoretical stand were about equal. Seed treatment of the regular entries in the open-pollinated and regular hybrid classes did not affect appreciably either stands or yield in 3 sections, but in the southern section a decrease in yield and stand resulted.

The highest-yielding section entries in the regular open-pollinated, regular hybrid, and experimental hybrid classes, respectively, were for the northern section Golden Krug, National Hybrid 110, and Iowa Hybrid 3215; the north-central section Golden Krug, North Central Iowearth BA, and Iowa Hybrid 3088; the south-central section Morcorn, Iowearth 25B, and Iowa Hybrid 3342; and in the southern section Reid Yellow Dent, Iowa Hybrid 13, and Iowa Hybrid 3395. In the southern section Iowa Hybrid 13 made the greatest relative increase in yield over the average open-pollinated varieties in the history of these corn yield tests, producing 26.9 percent more corn than its class average and 79 percent more than the open-pollinated class average.

In 4 of the 10 fields the lowest-yielding strain of all classes of entries was a regular hybrid, demonstrating that not all hybrids are good, and that the purchaser of hybrid seed should buy only known hybrids of proved worth.

Important factors in cotton growing in North Carolina, P. H. KIME (*North Carolina Sta. Agron. Inform. Circ. 106* (1937), pp. [1]+5).—The factors discussed include soils and their preparation, varieties, planting and spacing, cultivation, picking, storage, ginning, and handling of planting seed.

Results of cotton variety experiments, 1931–1936, P. H. KIME (*North Carolina Sta. Agron. Inform. Circ. 105* (1937), pp. [2]+5).—Varietal recommendations based on results of further tests with cotton (E. S. R., 73, p. 38) included certain strains of Mexican, Coker, Farm Relief, and Cleveland for the Piedmont; of Farm Relief, Cleveland, Coker, and Mexican for the upper Coastal Plain; of Coker, Foster, and Farm Relief for heavy and poorly drained soils in the lower Coastal Plain; and of Dixie-Triumph, Cleve-wilt, and Dixie for wilt-infested soils. Surveys in cooperation with the U. S. Department of Agriculture showed the percentage of $1\frac{5}{8}$ in. and longer cotton grown in North Carolina in 1936 to be 87.4 as compared with 20.3 in 1928.

Investigations on the mechanical application of fertilizers for cotton in North Carolina, with some results for other crops obtained in other States, E. R. COLLINS (*North Carolina Sta. Agron. Inform. Circ. 104* (1937), pp. [1]+17, figs. 4).—Results obtained in cooperative experiments with the U. S. Department of Agriculture, 1931–36, showed that the maximum benefit from normal and higher rates of fertilizer applications can be assured by side placement from 2 to 3 in. to the side and from 2 to 3 in. below the level of the seed. Placement to one side of the seed gave practically as good results as application to both sides. With a normal or heavy fertilizer application, high in nitrogen or potassium, to avoid injury the seed should not be placed too close to the fertilizer. Preliminary results indicated that where the fertilizer is applied in bands from 5 to 6 in. apart, 3 in. below the seed, and seed planted with a walking planter, good stands and yields are obtained.

Results obtained elsewhere by the U. S. Department of Agriculture and other agencies in fertilizer placement tests with other crops are also summarized.

Cotton fertilizers for Georgia soils, R. P. BLANDSON, S. V. STACY, and J. J. SKINNER (*Georgia Sta. Bul.* 196 (1937), pp. 20, figs. 5).—Fertility experiments with cotton were made, 1928-35, in cooperation with the U. S. D. A. Bureau of Plant Industry, at five locations in Georgia on Cecil sandy clay loam, Norfolk, Orangeburg, and Carnegie sandy loams, and Decatur clay loam, typical cotton soils.

The largest returns per acre from the cotton fertilizer were obtained when the fertilizer supplied 32 lb. each of nitrogen, phosphoric acid, and potash per acre, equivalent to the application of 533 lb. of a 6-6-6 fertilizer, 76 percent of the total increase being calculated as due to the nitrogen, 8 to the phosphoric acid, and 16 percent to the potash. The results of field demonstrations on 49 farms showed that increasing the quantity of fertilizer from 13-26-13 to 30-26-30 lb. per acre was followed by increased yields of 192 lb. of seed cotton per acre and increased profits of \$5.38 per acre.

Recommendations for average and special conditions in Georgia are outlined and suggestions made on buying fertilizers and fertilizer application.

A study of ammonia and nitrate nitrogen for cotton, III, IV, K. T. HOLLEY and T. G. DULIN (*Georgia Sta. Bul.* 197 (1937), pp. 24, figs. 4).—An extension of the study of ammonia and nitrate nitrogen for cotton (*E. S. R.*, 72, p. 88).

III. *Influence of the nitrogen concentration in the nutrient medium* (pp. 3-14).—Cotton plants grown in nutrient solutions containing high and low concentrations of nitrate nitrogen made better vegetative growth and produced slightly more bolls than those grown in comparable solutions with ammonia nitrogen. The ammonium salt solution plants tended to better fruiting in the early stages. The high concentration nitrogen solutions contained six times as much nitrogen as the low concentration media initially, but under influence of absorption by the plants the ratio increased in the later growth stages. These differences in concentration did not appreciably affect sap nitrogen or the total nitrogen percentage in the tissues of the nitrate plants in the early growth stages nor the total nitrogen of the seed at the end of the growth period. With ammonium salt solutions the higher nitrogen concentration in the medium produced plants with a higher sap nitrogen content and a higher total nitrogen content in the early growth stages and much higher content of nitrogen in the seed. The higher nitrogen content of the high ammonia nitrogen plant saps was most evident in the amide or asparagin nitrogen fraction. The nitrogen concentration in either case had no pronounced effect on the ash, calcium, magnesium, or oil content of the seed or on the iodine number of the oil.

Conclusions were that the accumulation of nitrates within the tissues is one of the principal factors governing the absorption response of the plants to variations in the concentration of nitrates in the medium, and that the increased absorption of nitrogen from the higher concentration ammonium salt solutions is in part due to the lack of appreciable accumulation of the ammonium ion in the tissues.

IV. *Influence of boron concentration* (pp. 14-23).—Although addition of 10 p. p. m. of boron, added as H_2BO_3 , resulted in a decided improvement in growth of cotton plants in nitrate-nutrient solutions in spring cultures not constantly renewed, it had no appreciable effect on growth and fruiting in summer cultures receiving ammonium salts and nitrates as nitrogen sources when compared with a much lower level of added boron. The higher added boron did not appreciably affect the fruiting tendency or boll production with either nitrogen source, and did not increase the boron content of the leaves in pro-

portion to amounts added. No interrelation between boron and calcium or magnesium utilization by the plant was evident. Since the fruiting tendency of nitrate plants was nearer that of ammonia plants at both high and low added boron levels in these plants, some factor other than added boron apparently was responsible for this variation from fruiting tendencies reported previously.

In early growth stages, 10 p. p. m. added boron had no appreciable effect on nitrogen fractions of saps of plants grown on either form of nitrogen as compared with those grown on a lower boron level. From pH measurements on the expressed saps of plants of these and previous cultures, acid-base balance seemed to be maintained at about the same level in saps of plants grown on either ammonium salts or nitrates, although nitrate plants have a more basic ash. Indications were that cotton plants supplied with ammonium salts tend toward a slightly lower water content than those receiving nitrates, but there was no evidence that the source of nitrogen directly influences the water economy of the plant.

Relative value of different brands of sodium nitrate in cotton production, H. P. COOPER, E. E. HALL, W. B. ROGERS, R. W. WALLACE, and R. L. SMITH (*South Carolina Sta. Circ. 56* (1937), pp. [4]).—Comparative tests, 1931–35, at the station and Pee Dee and Sandhill Substations did not reveal significant differences in yields of cotton receiving equivalent amounts of ammonia from three brands of sodium nitrate.

Cotton spacing (*Alabama Sta. Circ. 76* (1937), pp. 8).—Spacing experiments with cotton, 1924–35, at the station and substations led to the recommendation of 18 in. apart in the drill with from 1 to 3 plants per hill. Row widths with liberal fertilization may vary from 2.5 to 4.5 ft., while under low fertility conditions or with only moderate fertilizer applications row width should not exceed 3.5 ft. Of the two factors which were affected by variations in spacing, yield was influenced by variations in row width, distance between hills, and in number of plants per hill (largest yields coming from spacings giving from 8,000 to 25,000 plants per acre), and boll size was increased by wide spacings and decreased by close spacings. The optimum spacing was about the same on the different soil types on which the experiments were conducted.

Methods for the measurement of certain character properties of raw cotton, H. B. RICHARDSON, T. L. W. BAILEY, JR., and C. M. CONRAD (*U. S. Dept. Agr., Tech. Bul. 545* (1937), pp. 77, pls. 4, figs. 21).—Detailed improvements in methods for measuring strength, fineness, and maturity of cotton fiber are described; the merits and demerits of certain procedures previously used are pointed out; and pertinent literature is reviewed.

The Chandler bundle method (*E. S. R.*, 56, p. 496) for determining strength has been studied carefully and the technic more completely specified. Variables now controlled or corrected for include distance between threads at the center of the bundle, size of bundle, manner and amount of combing, and elongation of wrapping thread during wrapping of the bundle. The effect of sag of the bundle during wrapping is recognized and approximately evaluated. The calculation of the strength to an imaginary rod of pure cellulose has been abandoned, the results now being calculated to the area of the bundle cross section as determined by wrapping.

Improvements in the weight-per-unit-length method for estimating fiber fineness for a sample of lint include the use of entire fibers instead of cut sections, systematic sampling from all groups of fiber length in the sample, accurate weighting of the fineness in each length group in proportion to the fraction which that group contributes to the whole, and provision for a useful measure of variation of fiber fineness in the sample.

The improvements made in the Clegg method (E. S. R., 68, p. 282) for estimating fiber maturity in a sample of lint include a more extensive and adequate sampling process, sampling from all principal length groups of the length array, classification of fiber-wall types into two groups depending on ratio of lumen width to wall thickness, weighting of percentage of immature fibers of each group according to the fraction which that group contributes to the whole sample, and in simplification of the expression for maturity into a single figure—the immaturity count.

Soybeans: Their adaptation and production in Montana, A. H. POST (*Montana Sta. Bul. 335 (1937), pp. 11*).—The behavior of soybeans in experiments under irrigation and on dry land in Montana is described, with comments on choice of varieties, and cultural and harvest practices.

Experimental results with soybeans have not been favorable for seed or hay production on either dry or irrigated land, alfalfa and annual cereal grains producing more hay per acre. Soybeans should be planted only in areas where adapted varieties of dent corn mature normally, using such early varieties as Minsoy, Wisconsin Early Black, and Mandarin for seed and these and Manchu, Chestnut, and Soysoy for hay. Cultural methods similar to those used for corn and field beans are indicated.

I, Factors in soybean production; II, Variety recommendations and characteristics, R. L. LOVORN, P. H. KIML, and R. EL. STITT (*North Carolina Sta. Agron. Inform. Circ. 102 (1937), pp. [1]+6*).—Practical instructions for growing soybeans for seed, hay, soil improvement, pasture, and silage are outlined, and certain varieties indicated for various uses in different sections of the State are described briefly.

Tobacco Substation at Windsor, report for 1936, P. J. ANDERSON, T. R. SWANBACK, and O. E. STREET (*Connecticut [New Haven] Sta. Bul. 391 (1937), pp. 61-123, figs. 21*).—The progress of fertilizer and cultural experiments with cigar leaf tobacco (E. S. R., 76, p. 185) is reviewed as heretofore, and articles on control of diseases and insects, noted, respectively, on pages 351 and 361 of this issue, are included.

Experiments on irrigation (pp. 67-72).—Irrigation tests during several seasons on light, sandy soil with a coarse, sandy subsoil, a type that suffers from drought and from leaching, showed that if heavy irrigation is needed, application of nitrate is as important as the water. To date, no adverse effects of irrigation plus nitrates had been found on the quality or burn of tobacco, which was of unusually high quality. Experience on heavier soils at the station showed that irrigation (without addition of nitrate) could be practiced to a certain extent without serious injury from leaching. Further experimentation is deemed necessary to determine the optimum quantity of nitrate and more convenient methods of application.

Further experiments on time of harvesting Havana seed tobacco (pp. 73-75).—Results obtained so far (E. S. R., 76, p. 186) indicated that the grower will profit greatly by leaving the tobacco in the field for at least 3 weeks after topping, except when confronted with danger of leaf starvation on account of excessive rainfall, too little fertilizer, or a soil not retentive enough.

Soybean oil meal as a tobacco fertilizer (pp. 75-78).—All tobacco grown on plats with soybean oil meal as the nitrogen carrier in 1936, in comparison with cottonseed meal and general fertilizer, was excellent in quality with good color, texture, and veins. Significant differences were not apparent between yields produced by regular, pellets, or solvent process soybean oil meal, which all exceeded the checks. Nitrification studies revealed that soybean oil meal produces nitrate at a higher and more uniform rate than other organics, such as cottonseed meal, but without appreciable differences between the various

kinds of soybean oil meal tested. There was no material gain from applying soybean meal in pellet form. With shade-grown tobacco, soybean oil meal produced thinner and more elastic leaves than did cottonseed meal. In this test no increase in weight came from use of soybean oil meal, but enough improvement in quality occurred to net the dealer 9 ct. per pound above tobacco grown on the cottonseed meal formula.

Single sources versus mixed sources of nitrogen in the fertilizer (pp. 78-82).—Results over 5 yr., 1932-36, indicated that nothing is gained in yield or quality by combining several organics, a single organic giving as good results. However, indications were that the lower priced materials may well replace part or all of the more expensive ones. When potassium nitrate, supplying 40 lb. of nitrogen to the acre, was used in the fertilizer mixture as a starter, the plants did not start more rapidly nor was growth better in any way than when no nitrate was added, and furthermore, both yield and grade index were somewhat lower than when no starter was used.

Fractional applications of nitrate of soda (pp. 82-84).—Results from fractional applications of sodium nitrate were in line with those from organics, suggesting that the main, if not sole advantage of the various meals is equalled by supplying the nitrates at a proper rate. Nitrogen in sodium nitrate costs about half as much as any of the common meals, which permits a saving in fertilizer cost, but this must be balanced against the extra labor, mainly hand labor, involved in the fractional applications.

Studies on the anatomy of the tobacco leaf—I, *The midrib*, P. J. Anderson (pp. 98-107).—The present description of the midrib structure considers the epidermis, including glandular hairs and stomates, chlorenchyma, cortex, endodermis, xylem, cambium, phloem, and pericycle.

Broadleaf fertilizer experiments, J. S. Owens (pp. 118-123).—Cooperative experiments with Broadleaf tobacco on Hartford sandy loam, 1931-34, 1936, in which cottonseed meal and castor pomace were about equally satisfactory when supplying four-fifths of the nitrogen applied; urea could be used to supply half the nitrogen; 150 lb. of nitrogen in the mixture about equaled 200 lb.; and from 50 to 100 lb. of phosphoric acid was adequate for most fields, did not differ greatly from experimental results obtained with Havana tobacco at Windsor. Thus, it appeared that Broadleaf growers may safely use results from the fertilizer tests at Windsor as a basis for their own practices.

Inspection of agricultural seeds, H. R. KRAYBILL ET AL. (*Indiana Sta. Circ.* 225 (1936), pp. 110, fig. 1).—The purity, percentages of germination, and weed seed content, and for legumes hard seed content, are tabulated from tests of 1,362 official samples of seed collected from dealers in Indiana during the year ended June 30, 1936.

Seed inspection, F. A. McLAUGHLIN (*Massachusetts Sta. Control. Ser. Bul.* 86 (1936), pp. 81).—The purity, germination, and weed seed contents are tabulated for 206 official samples of field crop seed and germination for 532 samples of vegetable seed collected in Massachusetts during the year ended October 1, 1936. Results of field tests for trueness to type and variety on 135 lots of beans, beets, cabbage, carrots, lettuce, onions, parsnips, radish, spinach, squash, and turnips are included, with remarks on the quality of onion seed produced in the Connecticut Valley in the 1935 season. Studies of flower seeds made in cooperation with O. M. Hoeffle and C. L. Thayer, including tests of 104 samples of seed for purity, germination, and performance, are appended.

The herbicidal properties of boron compounds, A. S. CRAFTS and R. N. RAYNOB (*Hilgardia* [*California Sta.*], 10 (1936), No. 10, pp. 343-374, figs. 7).—Greenhouse studies on the toxicity and fixing of borax in Yolo clay loam, Stockton adobe clay, Fresno sandy loam, and Columbia fine sandy loam were supple-

mented by plat tests with borax and other boron carriers, dry and in solution, and in mixture with sodium chlorate and arsenicals.

High toxicity indicated in the greenhouse tests was less evident in the field, and the boron compounds were not retained in the soil against the leaching power of moving water to the same extent as arsenic. Consequently, applications must be heavy and often for complete sterilization. Borax loses rapidly in toxicity when held in a given mass of soil, and this action together with the loss by leaching reduces the effective concentration until seedlings are permitted to develop. Indications were that the use of boron in soil sterilization will be limited both by species present on the areas and the amount and distribution of seasonal rains.

Klamath weed is injured by high concentrations of salts in the soil solution and is highly susceptible to boron poisoning. Against more tolerant plants and in regions of fertile, recent alluvial soils, use of boron compounds seems limited to the coarser soils or graveled areas; and where annual rainfall exceeds 10 in., applications will be needed one or more times each year. It is emphasized that boron compounds must be used with caution near ornamental plants, around orchards or groves of citrus and walnuts, and in regions where a possibility of contamination of irrigation water supplies exists.

Response of quack grass to defoliation and fertilization, S. T. DEXTER (*Plant Physiol.*, 11 (1936), No. 4, pp. 843-851; *abs. in Michigan Sta. Quart. Bul.* 19 (1937), No. 3, pp. 193, 194).—Quackgrass in field plats and in the greenhouse received ammonium sulfate and other fertilizers. Frequent and complete defoliations killed both fertilized and unfertilized plants, but fertilized plants were weakened more rapidly in the early stages. Rhizomes taken from plants at various times throughout the spring and placed in a seed germinator decreased in ability to sprout as summer approached. Rhizomes from fertilized plants sprouted much more quickly and vigorously than those of unfertilized plants, which tended to remain vegetatively inactive.

On eradication plats, grass plowed at early bloom was killed more easily than that plowed either earlier or later. Fertilized grass always grew more rapidly at first after plowing, but was weaker than the unfertilized grass after being hoed off once or twice. Rhizomes of quackgrass that had been heavily fertilized with ammonium sulfate contained 2 or 3 times as much nitrogen as those from unfertilized grass. Fertilized rhizomes also produced new sprouts within a few weeks that weighed about 10 times as much and contained about 20 times as much nitrogen as sprouts from similar unfertilized rhizomes. The draft on the fertilized rhizomes for organic foods was far greater than in the case of unfertilized rhizomes. Quackgrass responded to nitrogen fertilization by producing greater top growth which was higher in nitrogen than grass from unfertilized plats.

HORTICULTURE

[Horticultural investigations by the Indiana Station] (*Indiana Sta. Rpt.* 1936, pp. 49-56, 65, 66, 67, figs. 7).—Among studies the results of which are briefly outlined are orchard soil management; apple pruning; spraying materials, equipment, and residue removal; varieties of peaches and plums; storage of apples; production of tomato seed; relation of nutrition and healthy foliage to quality in the tomato; correlation between the refractive index and sugar content in the muskmelon; manurial substitutes in greenhouse soils for roses and injurious effect of corrosive sublimate; storing, precooling, and freezing of fruits and vegetables; supplemental lighting in the greenhouse; growing of pyrethrum and determination of its pyrethrin content; effect of cultural treatment on growth and reproduction in the apple; and chemical studies on the quality of inbred and pure lines of sweet corn.

[Horticultural studies by the Tennessee Station] B. D. DRAIN and L. A. FISTER (*Tennessee Sta. Rpt. 1936*, pp. 44-47, 48, 52, 53, 54, 55, 64-66, 68, figs. 8).—Included are reports on projects in red raspberry and pyrethrum improvement; the development of fire blight-resistant pears, leaf spot-resistant tomatoes, and blight-resistant chestnuts; irrigation of vegetables; breeding of sweet corn; testing of ornamentals; mulching of red raspberries; soil reaction needs of flowering shrubs; fertilizers for young orchards; testing of new varieties of peaches and of early cabbages; and general notes on variety and cultural tests with asparagus, grapes, gooseberries, and plums.

[Horticultural studies by the Washington Station] (*Washington Sta. Bul. 342 (1936)*, pp. 22, 43, 44, 45-49, 61, 62-64, 67, 68).—Included are brief progress reports on the characteristics of maturing apples, by J. L. St. John; orchard cover crops, by O. M. Morris and F. L. Overley; peach harvesting, packing, and storing, by Morris; development of methods of propagating apple stock, by Morris; types and extent of winter injury, pollination of the apple, and effects of oil sprays on apple trees, all by E. L. Overholser and Overley; breeding strawberries, by C. D. Schwartz; fertilizer treatments for the orchard, by Overholser, Overley, and W. J. Clore; breeding raspberries for hardiness and disease resistance, by Schwartz and G. A. Huber; orchard irrigation, by Overholser and Clore; and tomato breeding, by C. L. Vincent.

Among studies reported from the Irrigation Substation are tests of sweet corn hybrids, by H. P. Singleton; soil moisture relationships in orchards, by C. A. Larson; response of apples to irrigation, control of fire blight in pears, varietal susceptibility of plums to winter injury, and variety trials of apples, peaches, and cherries, all by Clore.

Among projects of the Cranberry-Blueberry Substation discussed are weed control in cranberry bogs and fertilizers for blueberries, both by D. J. Crowley.

Carbon dioxide exchange rhythm and fruitfulness in plants of different reproductive habits, R. H. ROBERTS, J. E. KRAUS, and N. LIVINGSTON (*Jour. Agr. Res. [U. S.]*, 54 (1937), No. 5, pp. 319-343, figs. 28).—Employing large chambers approximately 30 cu. ft. in volume which permitted the use of entire potted plants of various species, such as the apple, potato, tobacco, buckwheat, and poinsettia, the Wisconsin Experiment Station found that blossoming plants have a more irregular curve of carbon dioxide exchange than do nonblooming plants. The authors suggest that carbon dioxide exchange is affected, probably, by the anatomical development that takes place and is related to reproduction merely because a correlation exists between anatomical conditions and fruitfulness. In certain plants such as spinach and tobacco, in which there was relatively little difference in the carbon dioxide utilization in blooming and nonblooming plants, there was also relatively little difference in anatomical character with blooming.

The failure of additional light to alter appreciably the diurnal carbon dioxide exchange curve, while it altered greatly the reproductive status, raises the question whether photoperiodism is not due to photochemical processes other than photosynthesis. The fact that the type of carbon dioxide utilization curve is correlated with the reproductive state of the plant is believed to indicate that a common physiological condition exists in all the reproductive plants studied.

The influence of rate of thawing on freezing injury of apples, potatoes, and onions, J. M. LUTZ (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 227-233, figs. 2).—In these studies potatoes, onions, and apples were generally more severely injured with rapid than with slow thawing. With the onion and the apple the differences in injury were not especially pronounced until very rapid thawing such as occurs in water or in air at 95° F. was employed. Injury

mented by plat tests with borax and other boron carriers, dry and in solution, and in mixture with sodium chlorate and arsenicals.

High toxicity indicated in the greenhouse tests was less evident in the field, and the boron compounds were not retained in the soil against the leaching power of moving water to the same extent as arsenic. Consequently, applications must be heavy and often for complete sterilization. Borax loses rapidly in toxicity when held in a given mass of soil, and this action together with the loss by leaching reduces the effective concentration until seedlings are permitted to develop. Indications were that the use of boron in soil sterilization will be limited both by species present on the areas and the amount and distribution of seasonal rains.

Klamath weed is injured by high concentrations of salts in the soil solution and is highly susceptible to boron poisoning. Against more tolerant plants and in regions of fertile, recent alluvial soils, use of boron compounds seems limited to the coarser soils or graveled areas; and where annual rainfall exceeds 10 in., applications will be needed one or more times each year. It is emphasized that boron compounds must be used with caution near ornamental plants, around orchards or groves of citrus and walnuts, and in regions where a possibility of contamination of irrigation water supplies exists.

Response of quack grass to defoliation and fertilization, S. T. DEXTER (*Plant Physiol.*, 11 (1936), No. 4, pp. 843-851; *abs. in Michigan Sta. Quart. Bul.* 19 (1937), No. 3, pp. 193, 194).—Quackgrass in field plats and in the greenhouse received ammonium sulfate and other fertilizers. Frequent and complete defoliations killed both fertilized and unfertilized plants, but fertilized plants were weakened more rapidly in the early stages. Rhizomes taken from plants at various times throughout the spring and placed in a seed germinator decreased in ability to sprout as summer approached. Rhizomes from fertilized plants sprouted much more quickly and vigorously than those of unfertilized plants, which tended to remain vegetatively inactive.

On eradication plats, grass plowed at early bloom was killed more easily than that plowed either earlier or later. Fertilized grass always grew more rapidly at first after plowing, but was weaker than the unfertilized grass after being hoed off once or twice. Rhizomes of quackgrass that had been heavily fertilized with ammonium sulfate contained 2 or 3 times as much nitrogen as those from unfertilized grass. Fertilized rhizomes also produced new sprouts within a few weeks that weighed about 10 times as much and contained about 20 times as much nitrogen as sprouts from similar unfertilized rhizomes. The draft on the fertilized rhizomes for organic foods was far greater than in the case of unfertilized rhizomes. Quackgrass responded to nitrogen fertilization by producing greater top growth which was higher in nitrogen than grass from unfertilized plats.

HORTICULTURE

[Horticultural investigations by the Indiana Station] (*Indiana Sta. Rpt.* 1936, pp. 49-56, 65, 66, 67, *figs.* 7).—Among studies the results of which are briefly outlined are orchard soil management; apple pruning; spraying materials, equipment, and residue removal; varieties of peaches and plums; storage of apples; production of tomato seed; relation of nutrition and healthy foliage to quality in the tomato; correlation between the refractive index and sugar content in the muskmelon; manurial substitutes in greenhouse soils for roses and injurious effect of corrosive sublimate; storing, precooling, and freezing of fruits and vegetables; supplemental lighting in the greenhouse; growing of pyrethrum and determination of its pyrethrin content; effect of cultural treatment on growth and reproduction in the apple; and chemical studies on the quality of inbred and pure lines of sweet corn.

[Horticultural studies by the Tennessee Station] B. D. DRAIN and L. A. FISTER (*Tennessee Sta. Rpt. 1936*, pp. 44-47, 48, 52, 53, 54, 55, 64-66, 68, figs. 8).—Included are reports on projects in red raspberry and pyrethrum improvement; the development of fire blight-resistant pears, leaf spot-resistant tomatoes, and blight-resistant chestnuts; irrigation of vegetables; breeding of sweet corn; testing of ornamentals; mulching of red raspberries; soil reaction needs of flowering shrubs; fertilizers for young orchards; testing of new varieties of peaches and of early cabbages; and general notes on variety and cultural tests with asparagus, grapes, gooseberries, and plums.

[Horticultural studies by the Washington Station] (*Washington Sta. Bul. 342 (1936)*, pp. 22, 43, 44, 45-49, 61, 62-64, 67, 68).—Included are brief progress reports on the characteristics of maturing apples, by J. L. St. John; orchard cover crops, by O. M. Morris and F. L. Overley; peach harvesting, packing, and storing, by Morris; development of methods of propagating apple stock, by Morris; types and extent of winter injury, pollination of the apple, and effects of oil sprays on apple trees, all by E. Larson; response of apples to irrigation, control of fire blight in pears, varietal susceptibility of plums to winter injury, and variety trials of apples, peaches, and cherries, all by Clore.

Among projects of the Cranberry-Blueberry Substation discussed are weed control in cranberry bogs and fertilizers for blueberries, both by D. J. Crowley.

Carbon dioxide exchange rhythm and fruitfulness in plants of different reproductive habits, R. H. ROBERTS, J. E. KRAUS, and N. LIVINGSTON (*Jour. Agr. Res. [U. S.]*, 54 (1937), No. 5, pp. 319-343, figs. 28).—Employing large chambers approximately 30 cu. ft. in volume which permitted the use of entire potted plants of various species, such as the apple, potato, tobacco, buckwheat, and poinsettia, the Wisconsin Experiment Station found that blossoming plants have a more irregular curve of carbon dioxide exchange than do nonblooming plants. The authors suggest that carbon dioxide exchange is affected, probably, by the anatomical development that takes place and is related to reproduction merely because a correlation exists between anatomical conditions and fruitfulness. In certain plants such as spinach and tobacco, in which there was relatively little difference in the carbon dioxide utilization in blooming and nonblooming plants, there was also relatively little difference in anatomical character with blooming.

The failure of additional light to alter appreciably the diurnal carbon dioxide exchange curve, while it altered greatly the reproductive status, raises the question whether photoperiodism is not due to photochemical processes other than photosynthesis. The fact that the type of carbon dioxide utilization curve is correlated with the reproductive state of the plant is believed to indicate that a common physiological condition exists in all the reproductive plants studied.

The influence of rate of thawing on freezing injury of apples, potatoes, and onions, J. M. LUTZ (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 227-233, figs. 4).—In these studies potatoes, onions, and apples were generally more severely injured with rapid than with slow thawing. With the onion and the apple the differences in injury were not especially pronounced until very rapid thawing such as occurs in water or in air at 95° F. was employed. Injury

was less in apples when the fruit was removed from the thawing medium promptly after thawing than when allowed to remain for some hours. A thawing temperature of about 40° adjacent to the frozen product is considered to be desirable for apples, potatoes, and onions under commercial conditions.

Synthetic manure-heated hotbeds, E. F. BURK (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 603, 604, fig. 1).—At the Oklahoma Experiment Station, hotbeds heated by a mixture of 7 lb. of calcium cyanamide with 100 lb. of prairie hay, straw, cotton burs, Bermuda grass, and weeds compared favorably with horse manure in efficiency. Treated cotton burs gave a higher temperature than horse manure and prairie grass an equal temperature. An advantage for calcium cyanamide was that the nitrogen formed NH_3 , which did not leach readily, and the calcium formed calcium carbonate, which favored alkalinity.

[Vegetable crop studies by the Illinois Station] (*Illinois Sta. Rpt.* 1935, pp. 265-280, 281, 282, figs. 2).—Included are brief reports on studies of the fertilization of truck crops, cover crops as a source of organic matter for truck gardens, time and extent of cutting asparagus plantings, fertilizers for asparagus, and varieties of tomatoes for canning, all by J. W. Lloyd and J. P. McCollum; breeding and testing of sweet corn hybrids, rate and method of planting sweet corn, fertilizers for sweet corn, and breeding of new tomatoes (for canning purposes) and lima beans, all by W. A. Huelsen; fertilizers for greenhouse tomatoes, by Lloyd; factors associated with the premature seeding of onions, by McCollum; and factors affecting the production of horseradish, by Lloyd, McCollum, and Kadow.

Floral primordia differentiation in beet and turnip, R. L. CAROLUS (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 518-522, figs. 8).—Detroit Dark Red beets harvested November 23 and replanted in a warm greenhouse after one month's storage at 55° to 65° F. produced noticeable flower stalks in only 50 percent of the plants after 35 mo. In contrast, beets held 1 mo. at 32° to 40° produced 100 percent flower stalks in the same period. Cold storage for 3 to 4 mo. resulted in strong seed stalk development in both beets and turnips, but it was not determined whether this improved growth was due to stimulation of low temperature or the superior preservation of the mother roots. In turnips, completely differentiated raceme primordia were found in roots stored 1 mo. under either cold or common storage. In beets, no flower stalk primordia were found in roots stored only 1 mo., showing that beets require a comparatively longer period of rest than turnips to cause initiation of flower development.

Statistical studies of apparently uniform fields of carrots and onions on peat soils, J. H. BEATTIE and V. R. BOSWELL (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), p. 472).—An analysis of records taken by the U. S. Department of Agriculture in plats established in six fields showed in five cases a high to very high noncorrelated variation in yield and a very low correlated variation. In general, multiple-row plats were less variable than single-row plats of equal area. Increase in plat size from 10 to 100 ft. of row in most cases resulted in a relative decrease of 40 to 60 percent in interaction variance and distinctly less decrease in total variance. The conclusion is reached that machine methods of planting and culture do not in themselves insure sufficiently uniform small plats to permit distinction of small differences without an inconveniently large number of replications.

Spacing studies with asparagus on a peat-sediment soil, G. C. HANNA (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 600-602).—Mary Washington asparagus planted in 1930 in rows 7.5 ft. apart with plants 12, 18, 24, 30, and 36 in.

in the row, in 1932 yielded 1,851, 1,483, 1,314, 1,009, and 901 lb. of green asparagus, respectively, and over the 4-yr. period 1932-35, yielded 10,400, 13,773, 12,650, 10,900, and 9,464 lb. There was very little difference in the average weight of spears between the various spacings. Although there was a progressive increase in the average number of spears per crown as spacing increased, the gain did not compensate for the smaller number of crowns per acre.

The development of early stringless beans by hybridization and selection. J. M. JENKINS, JR. (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 515-517).—Tennessee Green Pod, found to be the earliest and most productive bean under South Carolina conditions but possessing various undesirable characters, was crossed by the South Carolina Experiment Station with various commercial varieties. Beginning with the F_2 generation, plants which flowered about the same time as the Tennessee parent were saved. Of these several bore stringless fairly smooth pods. Further trial is required to determine disease resistance and yielding capacity, but the study had progressed sufficiently to show the possibility of developing early bean varieties by crossing commercial types with an unusually early kind.

Physiological factors associated with the fruiting habits of the bush lima bean. F. S. ANDREWS (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 473-476).—In 1935, plantings of Fordhook and Woods Prolific lima beans were made by the South Carolina Experiment Station on May 3 and July 15. The Woods Prolific greatly outyielded the Fordhook in both plantings. Stomatal activity was markedly different in the two varieties, the stomata of the Woods Prolific opening usually 20 to 40 min. earlier in the morning and closing 1 to 4 hr. later in the afternoon. The Woods Prolific had a greater chlorophyll content, a greater osmotic pressure of the leaf sap, a greater carbohydrate content, a lesser nitrogen content, and a greater carbohydrate-nitrogen ratio. Apparently stomatal behavior and chlorophyll content were very important factors in the different yielding capacities of these two varieties.

Variation in soluble solids within individual fruits of the cantaloupe and related melons. G. W. SCOTT (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), p. 523).—Measurements taken by the California Experiment Station at Davis with a Zeiss hand refractometer on the expressed juice from different parts of cantaloupes and watermelons showed the stem end to be lower than the blossom end in soluble solids. Sometimes this difference was as much as 3 to 4 percent. Usually there was a gradual increment along a horizontal plane from the stem to the blossom end. The soluble solids were higher in the flesh near the seed cavity than near the rind, but the differences were not large in fully ripened fruits. Determinations agreed rather closely with those made by a Brix hydrometer.

Plot technique in field celery experiments. D. COMIN (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 524-527).—Based on analysis of records taken on plats laid out in a celery field located on muck soil in Portage County, the Ohio Experiment Station found that with standard errors of 10-plant units before and after the effect of soil heterogeneity was removed estimated at 11.18 ± 2.15 and 11.18 ± 1.75 , respectively, approximately 100 celery plants were required to measure differences of 5 percent within an area of $\frac{1}{2}$ of an acre and 148 plants within an area of $\frac{1}{2}$ of an acre. Differences of 14 percent between any two plats were required for significance. The coefficient of variability of weight was the same before and after trimming the plants. Adjusting the plat yields to the yield of the normal stand by means of the plated regression resulted in no improvement as revealed by Fisher's analysis of variance.

[Pomological studies conducted by the Illinois Station] (*Illinois Sta. Rpt. 1935*, pp. 242-250, 251-255, 256-260, 261, 262, 264, 265, fig. 1).—Herein is briefly presented the progress of investigations in apple and peach breeding, by J. C. Blair, M. J. Dorsey, and J. S. Whitmire; pruning of the apple, by W. A. Ruth and V. W. Kelley; sources of nitrogen for apples, by Dorsey, R. S. Marsh, and Ruth; apple spraying, by H. W. Anderson; spray residue removal, by Ruth and K. J. Kadow; development of pears resistant to fire blight, by Anderson; cover crops for orchards, by Dorsey and Ruth; fertilizers for the peach, thinning peach fruits, and time of picking as related to quality of peaches, all by Dorsey and R. L. McMunn; zinc sulfate as a corrective for arsenical injury to the peach, by Anderson; selection of orchard sites, by Dorsey and Anderson; varieties of plums, by McMunn; rootstocks for cherries, by Dorsey and McMunn; varieties of small fruits and nuts, time of pruning grapes, and breeding of raspberries, all by A. S. Colby; and spraying the red raspberry to increase winter hardiness, by Anderson and Kadow.

Three distinct types of winter injury in trunks of fruit trees, F. C. BRADFORD (*Michigan Sta. Quart. Bul.*, 19 (1937), No. 3, pp. 179-182, figs. 2).—Descriptions are presented of three different types of winter injury with suggestions for remedial treatments.

The seasonal course of soluble nitrogen and phosphate phosphorus in the shoot growth of Winesap apple and Elberta peach, C. S. WALTMAN (*Kentucky Sta. Bul.* 367 (1936), pp. 157-191, figs. 18).—Employing a modification of the Emmert procedure (*E. S. R.*, 73, p. 583), determinations were made of the percentage of soluble nitrogen and phosphate phosphorus in samples of Winesap apple and Elberta peach shoots collected at weekly intervals throughout approximately a year from trees receiving different fertilizer and cultural treatments. With the peach the mean of soluble nitrogen for the dormant period was somewhat greater in three of five treatments than during the growing season. In the apple the percentage of soluble nitrogen was much lower in winter than in summer. During late summer and fall soluble nitrogen percentage was much higher in the peach than in the apple. The percentages of phosphate phosphorus in the shoots of apple were maintained at nearly the same level throughout the year with a similar relationship in the peach. In general, as soluble nitrogen increased, phosphate phosphorus decreased and vice versa. Precipitation influenced the accumulation of soluble nitrogen presumably by its influence on utilization in growth. This influence was much more pronounced in the peach than in the apple. Fertilizer treatments had no significant effect on the soluble nitrogen in peach trees either in summer or winter. The low percentage of soluble nitrogen in the shoots of apple trees in bluegrass sod suggested an association between the lack of available nitrogen and poor growth. Shoots from apples from the plots where millet and barley were used as cover crops averaged fully as high in percentage of soluble nitrogen as did those from trees where sweetclover and soybeans were grown.

The relation of nitrogen and soil moisture to growth and fruitfulness of apple trees under different systems of soil management, C. E. BAKER (*Indiana Sta. Bul.* 414 (1936), pp. 36, figs. 12).—Studies in a Grimes Golden and Delicious apple orchard planted in the fall of 1922 with differential treatments beginning in the spring of 1925 indicated the importance of soil management systems that increase or maintain the soil organic matter. Nitrate nitrogen content in the soil could not be correlated with tree behavior since considerable amounts were found in tilled soil receiving nitrogen fertilizer but with trees making poor growth. On the other hand, nitrates were seldom found under nitrogen-fertilized bluegrass sod or under a legume sod

in which the trees made satisfactory growth and yields. Total nitrogen was highest in soils receiving annual applications of a nitrogen fertilizer, except in the unfertilized legume plat where the soil was well supplied with organic matter. Nearly twice as much total nitrogen was found in the upper 8 in. of soil in all plats as in the 8-24 in. level. The unfertilized cultivated plat was lowest in total nitrogen. Trunk girth increment, terminal growth, leaf size, weight and thickness, fruit set, total yield, and size of fruit were directly correlated with total nitrogen in the soil and with an abundant nitrogen supply in the tree during the season of 1935.

During severely dry periods soil moisture was highest in soils containing the most organic matter. Heavy run-off, accompanied by serious erosion, occurred on tilled soils low in organic matter. Without nitrogen fertilizer it was not possible after 12 yr. of tillage and fall-sown crops of wheat or rye to secure even a moderate cover-crop growth. In 1935 the largest yields as well as the largest and most attractive Grimes apples, were produced on trees in permanent bluegrass receiving nitrogen. In the Delicious variety in 1935 the cultivated plats receiving nitrogen produced the highest total yield and smallest fruits. Despite the lesser yields, the fruit from the fertilized bluegrass and the legume plats was larger, more attractive, and of more economic value. In both varieties the fruit from the bluegrass and legume plats kept in good condition in cold storage longer than did the small fruits from the tilled areas.

Stock and cion effects in topworked apple trees, T. J. MANEY, H. H. PLAGGE, and B. S. PICKETT (*Amer. Soc. Hort. Sci., Proc.*, 32 (1935), pp. 332-335, fig. 1).—In an experiment at the Iowa Experiment Station in which an orchard was established in 1930 with trees budded on roots of known varieties, on French crab, and on Hibernial and Virginia crab intermediates with French crab roots, it was observed that although the rootstocks had a rather distinct effect on the growth of the top, variability was not reduced materially by any set of stocks. In growing seedlings from open-pollinated seed, the parents influenced definitely the vigor of the progeny. When budded to a recognized variety, the vigorous seedlings produced the better trees. In trees limb budded on Hibernial and Virginia crab there was less variability in the scion varieties on Virginia crab than on Hibernial, indicating that the intermediate stock had greatly influenced the uniformity of the trees and, in the authors' opinion, had an effect equal to, if not greater, than what could be expected with own-rooted trees.

Bridge-grafting vs. cleft-grafting girdled young apple trees, T. A. MERRILL (*Michigan Sta. Quart. Bul.*, 19 (1937), No. 3, pp. 175-177, figs. 2).—Based on observations on the recovery of apple trees injured by mice or rabbits, the author suggests the desirability of handling young trees less than 2 in. in diameter by cutting off the entire top below the girdling wounds and inserting scions by the cleftgraft method. Young trees treated in this manner made greater growth in the following years than comparable bridgegrafted trees, but there was danger of winter injury to the new tops because of their extremely rapid growth the first year or two after grafting.

The effect of lime-sulphur spray on the respiration rate of apple leaves, M. B. HOFFMAN (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 173-176).—Having shown previously (*E. S. R.*, 72, p. 619) that lime-sulfur sprays may decrease the rate of apparent photosynthesis of apple leaves, the author investigated the possibility that spraying with lime-sulfur may have increased the respiration rate, thereby supplying additional quantities of carbon dioxide for a normally functioning photosynthetic process. In the experiment, certain leaves

of young Baldwin trees, after running preliminary tests, were enclosed in black paper envelopes. There was some indication that the sprayed leaves respired at a slightly greater rate than the untreated, but in no measure was this sufficient to compensate for the decrease in the rate of apparent photosynthesis as recorded before covering with black paper. A second experiment gave the same general results, leading to the deduction that one is justified in concluding that lime-sulfur injury to apple leaves is due largely to the decrease in the rate of photosynthesis rather than to an increased rate of respiration.

The effect of bordeaux, copper, and calcium sprays upon carbon dioxide intake of Delicious apples leaves, W. J. CLORE (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 177-179, fig. 1).—Leaves of young Delicious apple trees growing in the greenhouses of the Washington Experiment Station were, after three days' preliminary readings with a modified Heinicke and Hoffman apparatus, sprayed with bordeaux mixture, copper sulfate, and hydrated lime. In general, the assimilation averages of treated and untreated leaves checked fairly closely with the exception of the calcium group, in which carbon dioxide undoubtedly was markedly decreased. Certain of the calcium-sprayed leaves showed distinct injury, first indicated at the extreme tips of the leaf blades. The only true symptom of bordeaux injury was seen on leaves sprayed only with copper sulfate.

Some notes on spray injury, H. G. SWARTWOUT (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 180-182).—Stating that spray injury in Missouri was more severe in 1935 than for many years, the author presents certain observations. On eight apple varieties, lead arsenate alone caused some russetting but less in all cases than when combined with lime-sulfur. Rome Beauty was exceptionally resistant to russetting. Reducing the concentration of lime-sulfur below the usual dilution without reducing the lead arsenate resulted usually in a better finish to the fruits. In combination with lead arsenate, dry lime-sulfur caused less russetting than did liquid lime-sulfur. In field tests, calcium caseinate failed to reduce russetting in the lime-sulfur lead-arsenate mixture. The zinc sulfate-hydrated lime mixture which has proved effective in reducing arsenical injury to peaches caused injury to apples.

Boron content of apples at different stages of development, J. C. JOHNSON and W. A. DELONG (*Plant Physiol.*, 12 (1937), No. 1, pp. 219, 220).—Analysis of Golden Russet apples collected from a manure-fertilized orchard located on a sandy loam soil indicated that in healthy fruits the boron content increases progressively throughout the season. The increase was relatively very rapid during the period of active cell division and of rapid growth in the month of June, suggesting the apparent importance of boron during the period of rapid growth of the fruit. The epidermal tissues (parings) were only slightly higher in boron than was the flesh.

A rapid method for determining the germinative power of peach seeds, F. FLEMION (*Contrib. Boyce Thompson Inst.*, 8 (1936), No. 4, pp. 289-293, fig. 1).—A simple method of determining the viability of peach seeds is outlined in which the naked embryos were mixed with granulated peat moss and held at room temperature. In 5 to 7 days at 20° to 25° C. the viable seeds showed hypocotyl development, and by 10 days all embryos were growing or showing deterioration. The percentage germination compared favorably with that secured when seeds were afterripened at 5° to 10° for the usual germination tests.

Bridge-grafting the peach, S. JOHNSTON (*Michigan Sta. Quart. Bul.*, 19 (1937), No. 3, pp. 177-179, fig. 1).—Elberta peach and Burbank and Lombard plum scions were used in an attempt to save mice-girdled 3-year-old peach trees. The results were that all the peach scions failed, 3 of 14 Burbank plum scions

lived, and 21 of 27 Lombard scions grew satisfactorily. However, where girdling was complete the trees did not recover even with bridgegrafting, indicating doubtful value of the operation with peach trees.

Some varietal differences in fruit development in peaches, R. V. LOTT and T. E. ASHLEY (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 258-264, fig. 1).—In this further contribution (*E. S. R.*, 72, p. 189), the authors present data on five peaches, Mayflower, Early Rose, Carman, Hiley, and Elberta, ranging in growing season from 62 to 129 days. In general, it was found that the first growth stage of the fruit, that is, up to the time the stone was hard enough to separate from the flesh, was much the same in all five peaches but thereafter the early maturing varieties proceeded to develop much more rapidly. The earliest variety, Mayflower, increased in dry weight of stone only 0.86 g from the beginning of the second growth stage to final maturity, while the stone of Elberta, the latest variety, gained 4.9 g up to the time of its maximum dry weight. The stones of the Mayflower peach never became completely hard, and the cotyledons developed only enough to half-fill the integuments when the flesh was mature. The other three varieties attained intermediate positions. Ether extract of the kernels of Mayflower and Elberta when the flesh was ripe were 0.34 and 30.84 percent, respectively. Apparently in late peaches such as Elberta, carbohydrates were used in the intermediate stages to develop greater dry weight of stone and kernel rather than flesh.

Peach tree fertilization, F. F. COWART and H. L. COCHRAN (*Com. Fert.*, 54 (1937), No. 1, pp. 15, 16).—Yield records taken in 1936 in a differential fertilizer experiment, conducted by the Georgia Experiment Station and the U. S. Department of Agriculture in an Elberta peach orchard planted in 1929, indicated that the application of 6 lb. per tree of a 4-8-6 fertilizer in the spring supplemented by an additional pound of nitrate of soda on June 1 was the most profitable treatment. The date of the heaviest picking was deferred as much as 4 days by fertilizer treatment beyond that of the nonfertilized trees. Color was adequate on all plats except those receiving 8 or 12 percent nitrogen. Trees receiving phosphorus and potassium but no nitrogen yielded no more fruit than the unfertilized trees.

Further observations on the relation of zinc sulfate on the control of arsenical injury on the peach, R. F. POOLE (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 183-185).—In 1935 when a protracted drought ended July 1 and was followed by a month of heavy rains and much cloudiness, the greatest arsenical injury in 8 yr. was recorded. In many cases, the fruits either decayed entirely or became worthless. Zinc sulfate added to the regular arsenate of lead and lime mixture reduced injury only slightly and was less effective than certain other amendments. Leaves and buds were not injured at any time during the season, and the trees held their foliage better than usual. Fruit injury did not appear where basic lead arsenate, 3 lb. to 100 gal. of water, was used.

Carotenoids of the peach, G. MACKINNEY (*Plant Physiol.*, 12 (1937), No. 1, pp. 216-218).—Studies at the University of California with powdered vacuum-dried Muir peaches and dried Lovell peaches indicated that the carotenoid fraction of the peach contains at least eight components, the four most abundant being β -carotene, cryptoxanthin, lutein, and zeaxanthin. Only a faint trace of α -carotene and none of lycopene or γ -carotene was found.

Seasonal influences upon the effect of shading in regard to setting of sour cherry fruits, L. R. LANGFORD (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 234-236).—In studies conducted by the Wisconsin Experiment Station, coverings of burlap, cheesecloth, and muslin placed over 8- to 12-year-old Montmorency cherry trees following the full-blossom stage and retained for about 3 weeks resulted in all cases in a smaller percentage set of fruits. The effects

varied from year to year and with the type of cloth. Certain uncovered trees supplied with supplementary electric light showed a slight increase in set. The greater drop of fruit from the shaded trees is believed due to a lack of available synthesized foods. There was some indication that temperature may have some effect on fruit setting other than its influence on pollination.

Additional notes on sweet cherry doubling, L. R. TUCKER (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 237-239, figs. 2).—Following an earlier paper (E. S. R., 75, p. 489), the author reports that double fruits occurred in 1935 in approximately the same amount as in 1932. As to the localization of doubling, 61 percent of the flowers from the buds on the top of limbs growing approximately horizontally on the southern exposure had double pistils while only 14 percent from the bottom quarter and 34 percent on both the eastern and western exposures were doubled. Light or temperature, or both, were apparently concerned in malformation. A study of temperature records at Lewiston showed high temperature periods in June of 1931 and 1934, the years preceding the large occurrences of double fruits, but unfortunately the periods did not coincide.

The origin of roots in several types of red and black raspberry stem cuttings, R. H. STODDS (*Amer. Soc. Hort. Sci. Proc.*, 32 (1935), pp. 380-385, fig. 1).—Following an earlier paper (E. S. R., 74, p. 344) dealing with the origin of roots in tip-layered plants of the Cumberland black raspberry, the author discusses the results of studies on other types of root development. In leaf-budded cuttings of the black raspberry, practically all the roots pushed out parallel to the epidermis and tangentially through the cortex, lifting the epidermal and collenchymatous tissues near the edges of the shield. In single-eye hardwood cuttings of Cumberland, the formation of roots was limited in all but two cases to the axillary buds. In softwood tip cuttings of Latham red raspberry, the root primordia arose in the primary rays beside certain vascular bundles which were readily distinguishable as leaf traces comprising the vascular supply of the leaves formerly in the nodes immediately above. Preceding or accompanying the appearance of the root primordia, there was a considerable amount of pericyclic activity not evident to any such degree in the black raspberry.

Raspberry nutrition.—II, Causes of raspberry failures in the coastal area of British Columbia, G. H. HARRIS (*Sci. Agr.*, 16 (1936), No. 7, pp. 353-357, fig. 1; *Fr. abs.*, p. 357).—In this second contribution (E. S. R., 73, p. 480), the author reports that most soil samples obtained from raspberry plantings have shown a nitrate value far below the optimum. Lime was also often deficient, and many low-yielding plants showed a phosphorus deficiency. Phosphates should be applied preferably a year or so in advance of lime because of a tendency of the two materials to form insoluble compounds. Potash in available form may run low in raspberry plantings, and sometimes its lack may be offset by applications of nitrate of soda, the sodium apparently replacing the potassium in the soil complex. Soil acidity is not considered necessarily harmful in itself but often results in reducing the availability of essential nutrients. Lime is sometimes required to render aluminum insoluble. Poor drainage often interferes with healthy root development.

Nitrogen in relation to the growth of citrus cuttings in solution cultures, A. R. C. HAAS (*Plant Physiol.*, 12 (1937), No. 1, pp. 163-172, figs. 5).—Following an earlier paper on phosphorus relations (E. S. R., 75, p. 631), the author presents the results of a preliminary study of the growth of citrus cuttings in solution cultures containing various forms and concentrations of nitrogen. When the culture solution was not renewed, nitrogen was the first element to become depleted. The roots became gelatinous and bluish in color, and a

strong odor of decomposing root tissue was evident. The tops showed no immediate effect, although there was a gradual loss of leaves. When calcium nitrate was added, the odor disappeared overnight and within a few days new roots were seen. The tops of Lisbon lemon cuttings grown in solutions with ammonia as the only source of nitrogen were larger with increasing concentrations of ammonia, but the leaves had the appearance of needing nitrogen. Concentrations of nitrite above 5 p. p. m. in the culture solution that contained 785 p. p. m. of nitrate were distinctly injurious to Lisbon lemon and Valencia orange cuttings.

[Floricultural studies by the Illinois Station] (*Illinois Sta. Rpt. 1935, pp. 282-288, fig. 1*).—Included are reports on progress of studies on the maintenance of fertility in greenhouse soils, by F. F. Weinard; classification and nomenclature of peonies, by Weinard and H. B. Dörner; and methods of cutting peony blooms, control of split calyx in carnations, rose varieties for forcing, and the spacing of carnation plants, all by Weinard.

Germination and seedling production in *Lilium* sp., L. V. BARTON (*Contrib. Boyce Thompson Inst., 8 (1936), No. 4, pp. 297-309, fig. 1*).—Recounting the advantages of producing lilies from seed, among them the securing of mosaic-free plants, the author discusses the results of studies with *L. auratum*, *L. canadense*, *L. japonicum*, *L. rubellum*, *L. superbum*, and *L. szovitsianum*. It was found that all these species require from 3 to 6 mo. at a high temperature of about 20° C. (68° F.) for the initiation and growth of the root, which is nondominant. After root growth began, a period of from 6 weeks to 3 mo. at a low temperature of from 1° to 10° was required before the dominant first leaves began their development. The results indicate the desirability of spring or summer planting out of doors, and wherever late fall and winter planting was not harmful the date had no effect. Tests on seeds of *L. concolor* showed prompt growth of both roots and cotyledon.

Fragrance in the garden, A. DORRANCE (*Garden City, N. Y.: Doubleday, Doran & Co., 1937, pp. 96, [figs. 10]*).—For the most part this book is devoted to the fragrance-supplying qualities of various ornamental plants.

Herbs and herb gardening, E. S. ROEDE (*London: Medici Soc., Ltd., 1936, pp. XIII+206, pls. [15, figs. 34]*).—This popular treatise is devoted to the making of an herb garden and the use of herbs as ornamental plants.

Roadsides: The front yard of the Nation, J. M. BENNETT (*Boston: Stratford Co., [1936], pp. [XVIII]+233, pls. [18]*).—This is a general discussion devoted largely to plant material and its utilization.

FORESTRY

[Forestry studies by the Indiana Station] (*Indiana Sta. Rpt. 1936, pp. 45-47, figs. 2*).—Brief reports are presented on the marketing of basket veneer and handle stock, wood lot management, the control of weed growth in nursery beds, and the possibility of transplanting one year Chinese arborvitae seedlings.

Effect of climate on timber-growth fluctuations, F. X. SCHUMACHER and H. A. MEYER (*Jour. Agr. Res. [U. S.], 54 (1937), No. 2, pp. 79-107, figs. 10*).—Annual ring widths from 1864 to 1926 of 12 dominant *Abies alba* sample trees taken from a 120-year-old stand of fir-spruce-beech near Aarau, Switzerland, were used to arrive at an estimate of the variation in annual ring width that is independent of the individuality of the tree and the effect of age. This magnitude, assigned to fluctuations of weather and climate, gives a coefficient of variation of 15.4 percent of the general average ring width of the data.

In an attempt to find out the part that one meteorological factor, precipitation, exerted on the widths of tree rings, orthogonal polynomials were fitted

to monthly precipitation for (1) each 13-mo. period, from August 1 of a preceding year to August 31 of a "current" year; and (2) each 15-mo. period from June 1 of a preceding year to August 31 of a current year. Progression equations, expressing the effect of variation in these polynomial coefficients on variation in ring width for corresponding current years, were transformed into functions which express the average effect of an added centimeter of rainfall per month during the 13-mo. (or 15-mo.) periods on width of annual ring. As a result, the simultaneous effect of precipitation upon the width of the current and succeeding annual ring is presented, indicating that precipitation exerts a permanent influence on next year's growth at about the same time (early July) that its influence on this year's growth passes its maximum, and reaches its own maximum, in turn, at the end of this year's growing season. From August on, the influence of precipitation on next year's annual ring width continues, although at a lessened rate.

DISEASES OF PLANTS

Some effects of plant diseases on variability of yields, C. HARTLEY and A. RATHBUN-GRAVATT (*Phytopathology*, 27 (1937), No. 2, pp. 159-171, figs. 3).—Examples of the effects of a single disease and of combinations of diseases on the variability of regional yields are analyzed. "Diseases may, in general, be expected to increase variation in production. The larger the variation of the disease losses or the more the disease losses tend to occur at times when other injurious factors also are active, the greater is the increase they produce in the variation of yields. Some diseases, however, are most serious in years otherwise favorable to the crop. Such diseases, if the loss variation is not too large, actually may decrease the variation in annual yields of a region as a whole. Late blight of potatoes appears to have become such a case—once a prime source of uncertainty, causing one of the great famines of history, and still a source of expense and worry to the individual farmer, it has been reduced to an apparently stabilizing factor, so far as regional and national yields are concerned and so long as the recommended spraying schedules are maintained.

"Stabilizing the yields of the individual grower is more essential from the standpoint of the producer than stabilizing regional yields. Disease losses to local communities or individual growers are more variable than regional losses, and diseases are, therefore, more likely to increase the variability of local yields than of regional yields.

"In the choice of problems for investigative emphasis, it is suggested that when other considerations are equal those diseases are particularly in need of attention, from the standpoint of both producer and consumer, in which variation is large or is negatively correlated with annual yields, so that better control will reduce yield variation."

The physiology of host-parasite relations, W. BROWN (*Bot. Rev.*, 2 (1936), No. 5, pp. 236-281).—Following a general introductory section, the bulk of this review discusses the stages of parasitism and the facultative and obligate parasites. Brief notice is given to acquired immunity in plants, and a bibliography of 149 titles is included.

Some aspects of the plant disease eradication and control work of the Bureau of Entomology and Plant Quarantine (*U. S. Dept. Agr., Bur. Plant Indus., Plant Disease Rptr.*, 1937, Sup. 99, pp. 17-46).—The following papers are included: The Dutch elm disease eradication program—objectives, methods, and results, by O. N. Liming; white pine blister rust control and barberry

eradication in 1936, by S. B. Fracker; barberry eradication developments; and control of phony peach disease, citrus canker eradication, and eradication of the peach mosaic disease, all by B. M. Gaddis.

The Plant Disease Reporter, April 15, May 1, and May 15, 1937 (*U. S. Dept. Agr., Bur. Plant Indus., Plant Disease Rptr.*, 21 (1937), Nos. 7, pp. 111-127, figs. 3; 8, pp. 129-142; 9, pp. 143-178, figs. 3).—The following items of interest are included:

No. 7.—Tobacco diseases in Canada, by G. H. Berkeley; potato diseases in Dade County, Fla., during the 1936-37 season, by G. D. Ruehle; white rust (*Albugo occidentalis?*) on Texas spinach, by J. S. Wiant; leaf diseases of nursery stock (trees and shrubs) in Illinois in 1936, by J. C. Carter; reports on apple scab for Rhode Island, New York, and Pennsylvania; and seed inspection for disease control, by M. T. Munn.

No. 8.—A survey of the tobacco downy mildew (*Peronospora tabacina*) situation in Florida, Georgia, South Carolina, and North Carolina March 23 to April 20, by P. R. Miller; relative susceptibility of lilac species and varieties to *Microsphaera alni* (including lists of those immune and of those slightly, moderately, and very susceptible), by I. H. Crowell; development of apple scab (spring of 1937) in Rhode Island, New York, and Ohio; fungi growing on decaying banana plants, by O. A. Reinking; and brief notes (including culture of *Sclerotinia trifoliorum* available, anthracnose (*Marssonina panattoniana*) on lettuce in California, powdery mildew (probably *Erysiphe polygoni*) on kale in Virginia, downy mildew (*Basidiophora entospora*) on China aster in Texas, and leaf rust on wheat reported for Texas).

No. 9.—Lists of plants attacked by miscellaneous plant-infesting nematodes (arranged alphabetically by genera and by species of parasite under which the hosts are listed), compiled by L. Crossman and J. R. Christie; the cereal rust situation, by H. B. Humphrey et al.; diseases of bur-clover and alfalfa observed in Georgia, by J. L. Weimer; notes on the incidence of leaf diseases of vegetable crops at the lower Rio Grande substation, Weslaco, Tex., in February, 1937, by G. H. Godfrey; apple diseases in New York; fruit diseases in Rhode Island, by F. L. Howard, and in Virginia, by A. B. Groves; and tobacco downy mildew in Kentucky and Tennessee, by W. D. Valleau.

[Plant disease work by the Illinois Station] (*Illinois Sta. Rpt. 1935*, pp. 250, 255, 256, 262-264, 280, 281).—Notes on the results of investigations are included as follows: Apple disease (measles) more serious than at first thought, studies greatly reduce damage from bacterial spot of peach, and *Phytophthora* root rot studies safeguard State's strawberry crop, all by H. W. Anderson; crossing controls leaf spot diseases of gooseberries, by A. S. Colby; and both bordeaux and copper sulfate dust aids beans, and *Verticillium* wilt of eggplant, both by K. J. Kadow.

[Plant disease work by the Indiana Station] (*Indiana Sta. Rpt. 1936*, pp. 27-29, 65, 66, figs. 2).—Reports of progress are given on the following: *Phytophthora cactorum* trunk canker of apple; tomato virus diseases; commercial fertilizers free from tomato mosaic virus; wheat diseases; corn diseases; and the effect of leaf rust (*Puccinia triticea*) on yield, composition, and quality of wheat (the last three in cooperation with the U. S. D. A. Bureau of Plant Industry).

[Plant pathology studies by the Tennessee Station] (*Tennessee Sta. Rpt. 1936*, pp. 48-50).—Brief statements by C. D. Sherbakoff are included on the progress of work relative to head blight and root rot of wheat; *Fusarium* wilt of cotton and of tomatoes (the latter with J. O. Andes); strawberry black root; tomato leaf spot control (with Andes); and anthracnose-resistant red clover, by J. K. Underwood.

[Plant disease work by the Washington Station] (*Washington Sta. Bul.* 342 (1936), pp. 49-53, 68).—Notes are given on studies of wheat smut, by F. D. Heald, C. S. Holton, and E. F. Gaines (cooperative with the U. S. D. A. Bureau of Plant Industry); bitter pit and related diseases of apple and pear, by Heald, R. Wellman, E. L. Overholser, and F. L. Overley; apple rots, by Heald and Wellman; pear rots, by Heald and H. English; diseases of forage grasses, by G. W. Fischer, Heald, and E. G. Schafer (cooperative with the U. S. D. A. Bureau of Plant Industry); virus diseases of potato and other solanaceous plants, by L. K. Jones and C. L. Vincent; virus diseases of peas, by Jones and F. Johnson; virus diseases of raspberries, by Jones; plant disease survey of the State, by Heald, Jones, and G. A. Huber (cooperative between the Western Washington Station and the U. S. D. A. Bureau of Plant Industry); and cuprocide for control of red leaf spot of cranberries, by D. J. Crowley.

The evaluation of some cuprous oxides recommended as seed-treatment products for the control of damping off, H. W. ANDERSON, K. J. KADOW, and S. L. HOPPERSTEAD (*Phytopathology*, 27 (1937), No. 4, pp. 575-587, figs. 4).—The relative merits as seed treatments for damping-off control of five different makes of cuprous oxide were compared, with the object of learning the necessary specifications of a satisfactory treatment, good commercial control of damping-off of several different vegetable crops being secured with four. The color of cuprous oxide is an unreliable index of treatment value for damping-off control. Attention is directed to the fact that proper seed treatment of peas, in addition to damping-off control, practically prevents the rotting of the cotyledons, which is reflected as increased vine growth and vigor.

Specifications of cuprous oxides to be used as seed-treatment materials for the control of preemergence damping-off are as follows: The product should contain no less than 95 percent cuprous oxide. Treatment should impart a smooth, uniform coverage to treated seed when used at recommended amounts. If the material is fluffy, flows evenly, and fumes or smokes when shaken, it may be considered dustable. The material should pass a 325-mesh screen. Additional fineness does not improve the fungicidal value. Certain detailed precautions are also given.

The relation of light to the diurnal cycle of sporulation of certain downy mildews, C. E. YAEWOOD (*Jour. Agr. Res. [U. S.]*, 54 (1937), No. 5, pp. 365-373).—In this study by the California Experiment Station, emergence of sporangio-phores of *Pseudoperonospora humuli* (hop mildew) through the stomata was first observed at 12 p. m., branching was complete and small sporangia had formed at 3 a. m., and sporangia were about full size at 6 a. m. and were mature and readily liberated at 9 a. m. Sporangia were caught in largest numbers on spore-trap slides at 9 a. m. and in decreasing numbers throughout the day. Sporulation of downy mildews of hop, onion (*Peronospora destructor*), grape (*Plasmopara viticola*), and lettuce (*Bremia lactucae*) was inhibited by artificial light at night. Hop and onion mildews sporulated most on infected leaves or plants placed in darkened damp chambers in the late afternoon or evening, and poorly or not at all when thus placed in the early morning. These two mildews failed to sporulate on leaves held in darkness at low humidity and different temperatures for 12 hr. or more, but did so when exposed for 12 hr. to natural or artificial light.

The diurnal cycle of sporulability in hop and onion mildew is believed to depend basically on the alternation of light and darkness in the normal day, but in leaves known to possess high sporulability the actual nocturnal sporulation depends directly on the frequently concomitant darkness and high humidity of night. The diurnal cycle of sporulability of onion mildew was not disturbed

by filling the central cavity of infected leaves with 5 percent sucrose or dextrose solutions or by placing cut leaves with their bases in either of these solutions.

Variability in the fire-blight organism, *Erwinia amylovora*, P. A. ARK (*Phytopathology*, 27 (1937), No. 1, pp. 1-28, figs. 2).—In this study of 10 isolates representing 6 localities and 8 susceptibles, marked variability of *E. amylovora* [= *Bacillus amylovorus*] in virulence was noted and correlated with morphological and some physiological characters. Dissociation was observed and studied. Aging of the culture invariably resulted in the appearance of rough forms, which proved to be stable in ordinary solid and liquid media but which reverted to the smooth type when passed 4-6 times through 2 percent sucrose or 1 percent glucose nutrient broth. The S type was the more virulent. The R type was avirulent for some susceptible shrubs and only slightly virulent to green pear fruits and succulent tips of pear seedlings. The R and intermediate types were obtained from old infections in nature. Ten percent sucrose broth decreased the invasive capacity of the culture but not by increasing the R forms, while 2 percent sucrose restored both attenuated and R forms to the virulent state.

The influence of varying sugar concentrations, such as occur in the nectar of fruit-tree blossoms, and the dissociation of the organism are believed to have an important bearing on the rise and decline of epiphytotics of fire blight.

Distribution and prevalence of *Ozonium* root rot in the shelter-belt zone of Texas, G. L. PELTIER (*Phytopathology*, 27 (1937), No. 2, pp. 145-158, pls. 2, figs. 2).—In this study by the Nebraska Experiment Station, the *O. omnicorum*-infested areas within the shelterbelt zone extending into southern Oklahoma and Texas in advance of planting were mapped with the object of avoiding these areas or using resistant trees, susceptible plant species being employed as indicators. The universal distribution of three susceptible weeds (horsenettles, ragweeds, and lambsquarters), as well as the presence of conidial mats, aided very materially in detecting *Ozonium*. A section of land was deemed infested when one or more diseased plants revealed the characteristic mycelial web on the roots or when conidial mats were found. On these bases the approximate limits of root rot infestation were found to be south of 34° N. lat. and east of the 100th meridian. In the main, prevalence of root rot was much more pronounced in the better agricultural lands and in the valleys. Repeated observations indicate that when root rot is found in the headwaters of a stream it usually is distributed throughout the drainage basin, and the incidence of root rot increases at the lower levels. The sharpness with which the infested and noninfested areas were delimited was especially striking.

New Zoopagaceae destructive to soil rhizopods, C. DRECHSLER (*Mycologia*, 29 (1937), No. 2, pp. 229-249, figs. 6).—"Three species of *Cochlonema* and one species of *Zoopage* are newly described herein, increasing the recorded membership of the Zoopagaceae from 22 to 26."

Sexual fusion in *Ustilago avenae* under natural conditions, J. H. WESTERN (*Phytopathology* 27 (1937), No. 4, pp. 547-553, figs. 6).—Initiation of the dikaryophase and the origin of the cells involved are important for the constancy of parasitic races of *U. avenae*. Although sporidia were produced readily in culture and caused infection when oat seeds were artificially inoculated with the proper combinations, it appears likely that in nature the dikaryophase is more often initiated by the union of adjacent promycelial segments, presumably of opposite sex. Opportunities for hybridization and for changes in pathogenicity are much less than if fusion of sporidia were common, because the nuclei of adjacent segments are derived from a single diploid parent nucleus. Occasionally the promycelium acts as an infection hypha and penetrates the seedling directly.

The present status of seed treatment, with special reference to cereals, R. W. LUTKEL (*Bot. Rev.*, 2 (1936), No. 10, pp. 498-527).—This comprehensive review (with 139 bibliographic references) considers the history of the subject, the advantages of dust treatments, problems in developing and testing seed treatments, diseases of cereals, ornamentals, vegetables, and other crops combatted by seed treatments, fungicidal materials, organic mercurials, centralized seed treatment, and the effects of seed treatment. It is concluded that "the constant aim will be to find or develop disinfectants that are highly toxic to parasitic fungi and bacteria but relatively harmless to the seeds and plants parasitized by them."

Studies concerning the reaction of barley to two undescribed physiologic races of barley mildew, *Erysiphe graminis hordei* Marchal, J. S. TIDY (*Phytopathology*, 27 (1937), No. 1, pp. 51-68, figs. 2).—The reactions of 85 barley varieties (seedling stage) to the two new physiologic races 6 and 7 were studied. In order to separate races 6 and 1, another variety (Heil Hanna 3 C. I. 682) was added to the list of four differentials used by Mains and Dietz (*E. S. R.*, 68, p. 770). Races 6 and 7 were tested on seedlings during the winter and spring under the differing environmental conditions then prevalent in the greenhouse, no marked changes in reaction to either race being shown at these two seasons. In spring adult plants were more resistant than seedlings of the same varieties, while in winter they were fully as susceptible.

Studies of F_2 and F_3 of three crosses between resistant and susceptible plants were also made in the greenhouse, race 6 being used as inoculum. The resistance of the three resistant parents proved in each case to be due to a single main Mendelian factor. (1) In the cross Svansota M736×Hanna C. I. 906, resistance was incompletely dominant. (2) In the cross Featherston C. I. 1118×Goldfoil C. I. 928, resistance was again incompletely dominant. In the F_2 test, conducted in the late spring in the greenhouse, heterozygous individuals have a type 2-3 reaction intermediate between resistance and susceptibility. In the winter, heterozygous F_2 plants were more resistant and gave 1-2 reactions. Independent inheritance of the factor pairs for resistance v. susceptibility and 2-row spikes v. 6-row spikes was indicated. (3) In the cross Arequipa C. I. 1236×Horsford C. I. 610, resistance was dominant. Independent inheritance of the factor pairs for resistance v. susceptibility and hoods v. awns was suggested.

The degree of bunt resistance necessary in a commercial wheat, G. A. WIEBE and F. N. BRIGGS (*Phytopathology*, 27 (1937), No. 3, pp. 313, 314).—In this cooperative study by the U. S. D. A. Bureau of Plant Industry and the University of California two hybrid wheats slightly susceptible to a physiologic race of *Tilletia tritici* gave 5.6 and 0.8 percent, respectively, of bunted heads under artificial inoculation in 1934, but without additional inoculum and even under conditions favorable for the disease were unable to produce enough inoculum to cause infection in subsequent years. It is concluded that, for practical purposes, slightly susceptible strains of wheat are suitable for commercial production.

A revision of the numbers assigned to physiologic races of the leaf rust of wheat, *Puccinia triticina* Eriks., H. B. HUMPHREY, C. O. JOHNSTON, and R. M. CALDWELL (*U. S. Dept. Agr., Bur. Plant Indus.*, 1936, pp. [11]+14).—To clarify the confused situation, adoption of the revisions here recommended and of the accompanying key and table of reactions is proposed to all investigators interested in the physiologic races of *P. triticina*. Certain features of the revision are briefly discussed. The bibliography includes 13 references.

Influence of stripe rust on growth, water economy, and yield of wheat and barley, W. M. BEYER (*Jour. Agr. Res. [U. S.]*, 54 (1937), No. 5, pp. 375-385,

figs. 3).—A resistant and a susceptible variety, each of spring wheat and spring barley, were grown to maturity in sealed containers in the greenhouse and infected with *Puccinia glumarum* at various stages of development. Though the two crops were grown in different seasons, the results were strikingly similar. Infection in early stages greatly reduced and retarded plant growth and reduced root production, grain and straw yield, plant height, and size and number of kernels. The effects were much less as inoculation was delayed, but there was material reduction in root and grain weight in susceptible varieties inoculated as late as anthesis. Reduction in grain yield was due to the decreased size and number of kernels and of heads per plant, and to the shriveling of the kernels. The effects were similar though less pronounced on resistant varieties, especially of wheat. The results obtained are stated to have been very similar to those reported by Caldwell et al. (E. S. R., 72, p. 61) and by Johnston and Miller (E. S. R., 73, p. 103), viz, the roots were most severely affected and apparently the most sensitive, and the development of the plant above ground, the grain yield, the kernels, and the water economy were affected in much the same way.

Comparative effectiveness of copper dusts in the control of celery leaf blights in 1936, R. NELSON and R. W. LEWIS (*Michigan Sta. Quart. Bul.*, 19 (1937), No. 3, pp. 159–162, fig. 1).—This is a report of further progress (E. S. R., 75, p. 214) in testing dust fungicidal treatments (copper oxide, basic copper sulfate, and copper sulfate-lime), from which it is concluded that no evidence is at hand of any superiority of the newer fungicides over the copper sulfate-lime combinations for control of the fungus leaf blights of celery. Bordeaux mixture (8–12–100) as a spray and copper sulfate-lime (20–80) dust are recommended as control measures until future tests prove that other fungicides are more effective or possess other advantages not apparent in the materials tested in 1936.

Black ear rot of corn, C. D. SHEERBAKOFF and L. S. MAYER (*Phytopathology*, 27 (1937), No. 2, p. 207, fig. 1).—This note from the Tennessee Experiment Station records the occurrence of black ear rot of corn caused by *Helminthosporium turcicum* as judged by isolations. It was observed only in a few highly inbred lines (F₇) of the Neal Paymaster variety.

The relation between the chemical nature of the substrate and the degree of chlorosis in corn, C. H. WADLEIGH, W. R. ROBBINS, and J. R. BECKENBACH (*Soil Sci.*, 43 (1937), No. 2, pp. 153–175, pl. 1, figs. 5).—Tests with five series of plants grown in sand culture supplied with culture solutions by continuous flow are described, the results of which were as follows: With nitrate as sole nitrogen source the severity of chlorosis increased progressively with each increase in pH value of the substrate from pH 3.0 to 7.0, while at pH 8.0 the plants were free. With both nitrate and ammonium sources of nitrogen there was much less chlorosis than with nitrate alone. With the proportion of anions and the pH value of the solution kept approximately constant, plants in the high potassium cultures were slightly chlorotic and those in the high calcium and high magnesium cultures moderately so. With the proportions of cations in the solutions approximately constant, plants in the high phosphate and high nitrate solutions were severely chlorotic, while those in the high sulfate solutions were free.

In general, high titratable acidity corresponded with high phosphate content of the expressed juices. An interrelationship between pH value and phosphorus content of the expressed sap is suggested to explain iron precipitation and the degree of chlorosis. There was a very close direct correlation between the nitrate-nitrogen content of the plants and the chlorotic intensity. It is suggested that iron precipitation and chlorosis are induced in high nitrogen

plants by the relatively higher proportions of metabolically active tissue with relatively high pH as compared with low nitrogen plants. Ammonium nitrogen in the medium was associated with a relatively higher phosphorus content and a relatively lower pH value of the expressed sap than was nitrate nitrogen. Plants grown in solutions containing ammonia were relatively free from chlorosis as compared with those grown in solutions containing nitrate as the sole nitrogen source.

The comparative role of certain nematodes and fungi in the etiology of damping off, or soreshin, of cotton, C. H. ARNDT and J. R. CHRISTIE (*Phytopathology*, 27 (1937), No. 4, pp. 569-572).—In this cooperative study by the South Carolina Experiment Station and the U. S. D. A. Bureau of Plant Industry, cotton seedlings were grown in soil cultures artificially inoculated with *Fusarium vasinfectum*, *F. moniliforme*, *Glomerella gossypii*, *Aphelenchoides parietinus*, *Aphelenchus avenae*, *Cephalobus elongatus*, and *Acrobeles bütschlii*, each alone; each of the fungi in combination with each of the nematodes; and each of the fungi with all four nematodes. The nematodes did not produce typical sore shin lesions and did not noticeably increase the severity of such lesions when combined with the several fungi, although they increased the stunting of the plants by *F. moniliforme*. Typical damping-off was caused by *G. gossypii*. The fusaria reduced germination and produced lesions on the hypocotyl but did not cause typical damping-off.

An experimental study of some fungi injurious to seedling flax, I. W. TEEVER (*Phytopathology*, 27 (1937), No. 4, pp. 531-546, figs. 3).—It is concluded that several soil organisms may be factors in the development of "flax sick" soil and that fungi other than *Fusarium lini* may blight the seedlings or injure the flax roots and thus account for an apparent loss of resistance to wilt. Six isolates of *Helminthosporium* (2 from flax roots, 2 from barley, 1 from wheat, and 1 from rye) proved extremely virulent on Winona flax seedlings in the greenhouse. The pathogenicity of two isolates was high at 80° F. but negligible or low at 70°, while that of the other four was not affected by the temperature range used. Some isolates of *Rhizoctonia solani* from flax, sugar beet, legumes, tomato, eggplant, and barley caused severe damping-off in flax, but isolates from potato usually were not so injurious. One strain of *Pythium*, isolated from wilt-sick soil, also caused damping-off of flax, but five species of *Phytophthora* failed to injure it. Root lesions, root rot, and occasionally stunting of the plant occurred when flax was attacked by *Thielavia basicola*, *Ophiobolus cariceti*, and a few isolates of *Alternaria*.

The type and severity of injury to flax by these fungi varied according to soil type and flora. *Ophiobolus* and *Thielavia* caused greatest injury in steamed soil. *F. lini* was extremely virulent throughout and *Helminthosporium* was also virulent on all soils, but the type of injury varied somewhat.

Studies on "damping off" of cultivated mushrooms and its association with *Fusarium* species, F. C. WOOD (*Phytopathology*, 27 (1937), No. 1, pp. 85-94, figs. 2).—Damping-off, a serious new disease of cultivated mushrooms, was continually associated with *Fusarium* spp. in the casing soil, and by the use of selective media *F. oxysporum*, *F. martii*, *F. culmorum*, *F. flocciferum*, *F. redolens*, *F. sambucinum*, and *F. sambucinum* f. 6 were obtained in pure culture.

F. oxysporum and *F. martii* were the commonest and were studied in detail. Successful inoculations on cultivated mushrooms are described, and symptoms identical with those in commercial beds were obtained.

Certain viroses of the garden pea, *Pisum sativum*, M. W. STUBBS (*Phytopathology*, 27 (1937), No. 3, pp. 242-266, figs. 3).—Symptomatologically different pea-mosaic viruses and the tobacco ring spot virus were studied in field

and greenhouse. One pea-mosaic virus differed sufficiently from other legume-mosaic viruses to justify designating it as a distinct virus (pea virus 1). Three others differed in symptoms on peas but were alike in all other characteristics studied and are designated as pea virus 2A, 2B, and 2C.

Symptoms of enation pea mosaic (pea virus 1), marble pea mosaic (pea virus 2A), speckle pea mosaic (pea virus 2B), mild pea mosaic (pea virus 2C), and tobacco ring spot virus infection on Alderman pea seedlings are described. The pea-mosaic viruses studied were readily transmitted by *Macrostaphum pisi* and by plant extract when carborundum was used as an abrasive. The 34 varieties of peas inoculated were all more or less susceptible to pea virus 1 and the tobacco ring spot virus. Pea viruses 2A, 2B, and 2C infected all but 6 varieties of peas inoculated. Studies of physical properties of the pea-mosaic viruses showed that pea virus 1 is inactivated by 1:3,000 dilution and 4 days' aging in vitro and the 3 strains of pea virus 2 by 1:1,500 dilution and 24 hours' aging in vitro. In seed transmission tests involving 13,328 seedlings, only 3 questionable cases of seedling infection from seed were observed. Host range studies showed important differences between pea virus 1 and the 3 strains of pea virus 2. Peas and sweet peas are the only hosts not previously reported for the tobacco ring spot virus.

Viruses other than those here described are believed to cause pea mosaic diseases.

Recent developments in potato breeding for resistance to virus diseases, E. S. SCHULTZ, C. F. CLARK, W. P. RALEIGH, F. J. STEVENSON, R. BONDE, and J. H. BEAUMONT (*Phytopathology*, 27 (1937), No. 2, pp. 190-197).—In this cooperative study between the U. S. D. A. Bureau of Plant Industry and the Maine and Maryland Experiment Stations, data on the inheritance of resistance to mild mosaic and the reaction of seedlings and varieties to other viroses are recorded. Potato varieties and seedlings varied in their reactions to viroses, some being completely resistant, some failing to contract the virus in the field but becoming infected in graft tests, others rarely contracting the virus in the field but becoming infected in grafts, and still others contracting the virus readily by both field exposure and grafts. No definite evidence of resistance to vein-banding mosaic was found. Katahdin was completely resistant to mild mosaic in field-exposure tests, but it is not homozygous for this character. A total of 120 seedlings, selections from different crosses and inbred lines, and 337 lots of South American varieties were exposed to spindle tuber during 1933 and 1934. The results showed some variation in the amount of spread, but it was difficult to determine whether the plants were resistant or only disease-escaping. Most of the 880 seedlings, tuber-grafted with spindle tuber in 1935, became infected. There was great variation in symptoms produced on the different varieties. Field-exposure tests (1933-34) to determine resistance to leaf roll proved unsatisfactory. Transmission by tuber grafts indicated a wide variation in the reaction of different seedlings to this disease. The variations of symptoms of spindle tuber and leaf roll, as expressed in different seedlings, indicate that if varieties cannot be found that will not contract these diseases some may be found that are highly tolerant.

A bacterial wilt and soft rot of the potato in Maine, R. BONDE (*Phytopathology*, 27 (1937), No. 1, pp. 106-108, figs. 2).—In this study from the Maine Experiment Station a bacterial disease is described which apparently is not yet generally distributed in Aroostook County. It has been seen most commonly on Green Mountain, but occurs also on Irish Cobbler and Katahdin potatoes. The organism responsible for the disease has not yet been fully identified.

The relation of rainfall to the development of late blight of Irish potatoes in the coastal section of South Carolina, W. D. MOORE (*South Carolina Sta. Circ.* 57 (1937), pp. 8).—This disease is reported to have developed in the coastal section of the State only five times during the past 20 yr. Mean temperature and relative humidity do not appear to affect materially its development, but there is apparently a relation with the amount and distribution of rainfall during the potato growing season.

In general, any regular spraying or dusting program is considered uneconomical, but from rainfall data accumulated during the early part of any growing period it is possible to predict the time and frequency of spray or dust applications advisable for control of the disease. From the rainfall data presented for a 20-yr. period, it would also appear possible to predict seasons when control measures would be desirable.

Breeding of potato varieties resistant to *Phytophthora* [trans. title], F. F. SMOBOV (*Phytopathology*, 27 (1937), No. 3, pp. 211-241, fig. 1; *Eng. abs.* pp. 239, 240).—By studying a large collection over a 10-yr. period it has been established that all species and varieties of cultivated potatoes are susceptible to *P. infestans*. Nine wild species from Mexico proved resistant, and their utility for selection is said to depend on their taxonomic position. The species most widely used for hybridization is *Solanum demissum*. The hybrids of *S. demissum* × *S. tuberosum* (already in their second generation), especially using backcrosses with *S. tuberosum*, combine resistance with the yields and other characters of domestic varieties. The use of *S. antipovicii* for selection is also quite possible but more difficult, as its negative influence in crosses with *S. tuberosum* is more marked than in the hybrids of *S. demissum* × *S. tuberosum*.

A study of scab resistance in the potato, H. M. DARLING (*Jour. Agr. Res.* [U. S.], 54 (1937), No. 4, pp. 305-317, figs. 7).—In this cooperative study by the Minnesota Experiment Station and the U. S. D. A. Bureau of Plant Industry, the scab resistance of about 300 inbred potato seedlings was tested in the field on scab-infested soil. Wide ranges in susceptibility, but no immune sorts, were found. There was no consistent association of scab resistance with a russet skin. The progeny of certain inbred resistant seedlings were nearly all resistant, indicating their possible value as breeding stock.

The lenticel structures in a resistant and a susceptible seedling were compared. The lenticels of the susceptible seedling were larger and the cells were rounder and more loosely arranged than those of the resistant one. In the resistant seedling the periderm was suberized earlier and extended farther into the lenticels, apparently affording greater protection against infection. The lenticel structure is considered one of the factors in scab resistance.

Sclerotinia rot of Irish potatoes, A. H. EDDINS (*Phytopathology*, 27 (1937), No. 1, pp. 100-103, figs. 2).—In this contribution from the Florida Experiment Station, the symptoms of potato infection with *S. sclerotiorum* are described. The inoculations reported indicate that infection may be due either to ascospores or mycelium. New hosts for the fungus are *Calceola officinalis*, *Erechtites hieracifolia*, and *Radicula obtusa*.

Inoculations of potato plants with *S. intermedia* gave negative results, but a rot very similar to that caused by *S. sclerotiorum* was induced by *S. minor*.

Keeping quality of sugar beets as influenced by growth and nutritional factors, F. G. LARMER (*Jour. Agr. Res.* [U. S.], 54 (1937), No. 3, pp. 185-198, fig. 1).—In Utah tests, sugar beets grown under conditions of adequate and inadequate phosphate supply were compared as to keeping quality under commercial storage-pile conditions, samples being stored in coarse-meshed onion sacks. Roots from plats fertilized with superphosphate or complete fertilizer

high in phosphate showed significantly less decay than those from unfertilized plots. Isolations showed *Phoma betae* predominantly associated with rotting in storage. Phosphate fertilization apparently reduced the loss by respiration of sucrose reserves in the roots. In other field tests, phosphate fertilizer and, to some extent, nitrogen applications improved the keeping quality. Barnyard manure, alone or with phosphate or nitrogen, and adequate soil moisture during the growing season influenced the keeping quality favorably, possibly by affecting the phosphate availability. Inoculations with *P. betae* corroborated the field results, sugar beets grown with adequate phosphate showing significantly less decay at 4°–6° and 18°–22° C. than unfertilized controls.

Tobacco diseases in 1936, P. J. ANDERSON (*Connecticut [New Haven] Sta. Bul. 391 (1937), pp. 108–117, figs. 6*).—Observations and notes on the prevalence of diseases include *Pythium* damping-off in the seedbed, *Rhizoctonia* bed rot, wildfire, a wildfire-resistant strain of tobacco, blackfire, frencing, *Thielavia* root rot, mosaic, physiological brown spot on shade tobacco, weather injuries, and pole rot (due to *Alternaria tenuis* and other fungi).

A progress report is also included of "studies on pole rot—II, vein rot", continuing the investigation previously reported (E. S. R., 76, p. 206). The term "pole rot" applies to what is probably a group of diseases caused by different organisms and exhibiting different symptoms. *A. tenuis* was the fungus most commonly associated the past season, and isolations and inoculation tests indicated its causal relation to the vein rot form of the disease. A study was also made of the penetration of the epidermis and of the mycelium within the tissues of the midrib.

A comparative study of *Bacterium tabacum* Wolf and Foster and *Bacterium angulatum* Fromme and Murray, A. C. BRAUN (*Phytopathology*, 27 (1937), No. 3, pp. 283–304, figs. 4).—In this study by the Wisconsin Experiment Station the progeny of six single-cell strains of *B. angulatum* [= *Phytomonas angulata*] and four of *B. tabacum* [= *P. tabaci*] of known pathogenicity were used. Attempts to secure differential characters of these organisms by morphological, cultural, physiological, and serological methods failed. *B. tabacum* displayed a tendency to lose its ability to secrete a soluble exotoxin when carried in pure culture for prolonged periods. Symptoms produced in tobacco by these nontoxigenic wildfire bacteria were often indistinguishable from those produced by *B. angulatum*, the cause of angular leaf spot of tobacco. The two organisms are recognized as being closely related, but because of distinct differences in pathological behavior it is not considered justifiable to place them in the same species.

Studies on representative strains of tobacco-mosaic virus, J. H. JENSEN (*Phytopathology*, 27 (1937), No. 1, pp. 69–84, figs. 7).—Symptoms of 12 tobacco-mosaic virus strains, representative of the range of symptoms produced by 53 strains, are described for tobacco, *Nicotiana sylvestris*, and *N. glutinosa*. One strain, from a slow-moving, necrotic-type strain on tobacco, killed tomato plants. Two strains produced unusually small lesions on leaves of *N. glutinosa*. Single pin-puncture inoculations of some strains to young tobacco plants produced as high as 50 percent infection, other strains were transmitted in less than 1 percent of the trials, and still others ranged between these two extremes. Infectivity trials using the local-lesion method gave similar results. All strains tested withstood 10-min. exposures to 80° C.

Quantitative studies of tobacco-mosaic virus inactivation by ultra-violet light, W. C. PRICE and J. W. GOWEN (*Phytopathology*, 27 (1937), No. 3, pp. 267–282, figs. 2).—The survival values of tobacco-mosaic virus exposed to ultra-violet light are shown to follow a simple exponential curve which is interpreted to mean that absorption of a single unit of energy within a vital portion of a

virus particle is sufficient to cause inactivation of that particle. The rate of inactivation (hence the slope of the survival curve) depends on the amount of energy incident to the virus. When the virus is most purified (as in a solution of crystalline material) and the solution has least extraneous matter to absorb the energy, the rate of inactivation is greatest. Adding juice of healthy tobacco plants to purified virus lowered the rate of inactivation. The rate for crystalline material plus the juice of healthy tobacco plants proved identical with that for virus in the juice of diseased plants. The rate of inactivation of virus in dried material was essentially the same as that for the wet material, except that a portion of the virus failed to become inactivated even after relatively long exposures. This is believed to be due to the fact that some of the virus particles in dried material, because of their fixed position, were overlain by other material and shielded from the ultraviolet light.

Factors relating to the control of ordinary tobacco mosaic, J. JOHNSON (*Jour. Agr. Res. [U. S.], 54 (1937), No. 4, pp. 239-273, figs. 7*).—Using the local-lesion method to determine concentration, cooperative studies by the Wisconsin Experiment Station and the U. S. D. A. Bureau of Plant Industry were made on the survival and inactivation of tobacco virus 1 in dead tissues of a hybrid tobacco exposed to different environmental conditions. Laboratory infection and dissemination tests were also conducted, supported by field records of disease development.

The results indicate that the virus survives in sufficient quantity in harvested tobacco and in field refuse to account for infection from such sources. Some brands of cigars and cigarettes carried fairly high virus concentrations, but other forms of commercial tobacco carried little or none. Virus in field refuse may be largely inactivated when fully exposed to weathering and decay for 5-6 mo. Under field conditions the virus survived at high concentrations in the roots until the succeeding crop was planted. In the absence of freezing and desiccation, some virus may also survive as long as 2 yr. in close association with the soil. Infection from the soil occurs through contact of the stems or leaves. Storms which favor wounding and increase in the area of contact with the soil favor infection in this manner. Although direct infections from the soil may rarely exceed 25 percent, subsequent dissemination from plant to plant by various cultural practices accounts for still higher percentages of mosaic. Field records show that the unusually dry season of 1936, favoring inactivation of the virus in the surface soil by desiccation, resulted in an exceptionally low percentage of infection.

Control of peach leaf curl by autumn applications of various fungicides, E. E. WILSON (*Phytopathology, 27 (1937), No. 1, pp. 110-112*).—Fall applications of bordeaux mixture (2-5-50 and 5-5-50), liquid lime-sulfur (4-50), and Basicop (3-50) gave efficient control, and Coposil (3-50), though not as efficient as the other materials, gave a fair degree of control. A bordeaux application (5-5-50) about 3 weeks before the buds began to swell gave no better control than did the fall application.

Peach mosaic, its identification and control, L. M. HUTCHINS, E. W. BODINE, and H. H. THORNBERRY (*U. S. Dept. Agr. Circ. 427 (1937), pp. 48, figs. 32*).—Continuing the study of this disease (*E. S. R., 67, p. 701*), now known to occur in Texas, Colorado, California, Utah, New Mexico, and Arizona, it has been found that, although its effects are variable among the horticultural varieties of peaches, its identification may be made by one or more of the following symptoms: Breaking in the flowers, retarded spring foliation, variously mottled and deformed leaves, twig abnormalities, and fruit malformations. The incubation time after graft infection varies with the time of year and the point of introduction. Spring inoculations usually induce symptoms during the same

growing season, while midsummer or fall infections usually do not show signs until the following spring. For the majority of new cases in a given year the symptoms first appear in the spring. Similar symptoms have been observed in *Prunus* species other than the peach.

The virus is not spread from diseased to healthy trees by irrigation water, pruning implements, or by other mechanical contacts. In limited tests it was not carried by viable pollen from a diseased tree, and seedlings from mosaicked seeds grew normally. The disease was not transmitted through the soil. However, under conditions favorable for its spread, it has proved to be one of the most contagious of the peach virus diseases. Though not yet demonstrated, it is believed that the natural vector is an insect.

Cultural methods, fertilizers, sprays, or injection of chemicals have not proved effective for control. However, in an outbreak in Colorado, thorough removal of affected trees in early spring and at frequent intervals throughout the growing season is proving effective in bringing the disease under control.

Comparisons of some old and new materials for spraying cherries (*Michigan Sta. Quart. Bul.*, 19 (1937), No. 3, pp. 123-142, figs. 9).—Two papers are included under this heading.

New copper sprays for control of leaf-spot, D. Cation (pp. 123-132).—The comparative value of old and new preparations for cherry leaf spot control was tested under favorable conditions for its development, the copper sprays proving effective. High-calcium bordeaux mixture and red copper oxide gave too much injury for recommendation under Michigan conditions. The other three copper compounds tested gave definitely better control than lime-sulfur when long periods elapsed between applications or when fewer were made. The copper sprays showed eradivative tendencies toward old infections and killed the fungus without inducing leaf drop, while infected leaves sprayed with lime-sulfur turned yellow and dropped. "Cupro K" gave the most effective control over an extended period.

Effect of some copper and sulphur fungicides on the tree and fruit of Montmorency cherry, E. J. Rasmussen (pp. 132-142).—On the basis of tests reported it is recommended that growers who have obtained good control of leaf spot with lime-sulfur should continue to use it. Bordeaux mixture, because of its injurious effects, is not recommended. Some of the newer copper compounds (e. g., Cupro K, "ZO", and Oxobordeaux) are promising and safe enough for trial in a limited way in commercial orchards. Although these new preparations gave control with fewer applications under the experimental conditions, it is advised that they be used only with the same timeliness and thoroughness as are employed with lime-sulfur.

The rosette disease of blackberries and dewberries, A. G. PLAKIDAS (*Jour. Agr. Res.* [U. S.], 54 (1937), No. 4, pp. 275-303, figs. 9).—The results of a study of the rosette disease and its causal agent are presented by the Louisiana Experiment Station. Rosette proved to be identical to the "double blossom" of blackberries and dewberries described by Cook (E. S. R., 23, p. 453) and others. The causal fungus is *Cercosporcella rubi* n. comb. (= *Ramularia rubi*), for which a revised description is given. The cardinal temperatures for the fungus in culture were about 6°, 25°, and 30° C. Pathogenicity was established by repeated inoculations, infection being obtained on wild and cultivated species and varieties of blackberries and dewberries. The infection period is shown to be limited, spontaneous infection not usually occurring after the last week of May or the first week of June. Temperature is believed to be the chief factor in limiting the time of infection, the prevailing summer temperatures for Louisiana being higher than the optimum for the fungus.

The fungus occurs in the mycelial stage within the vegetative and flower buds of the host and sporulates only on the open withering blossoms in spring. No intercellular or intracellular invasion of the tissue has ever been observed. The mycelium is closely associated with the embryonic elements of the vegetative and floral buds and probably obtains its nourishment by direct absorption through the thin walls of the young cells. In infected pistils the fungus prevents fusion of the carpellate walls, so that a prominent channel (stylar canal) is left in the carpel wall which is filled with hyphal strands that connect the mycelium in the ovary cavity with that outside. Mycelium also occurs within the ovule. Under certain conditions (described) infection may become systemic in the crowns of dewberry plants arising from tip rootings of rosetted canes. This does not occur in the upright blackberries.

Strawberry root rot in Utah, B. L. RICHARDS and H. H. MCKAY (*Utah Acad. Sci., Arts, and Letters, Proc.*, 13 (1935-36), pp. 17-19).—In this contribution from the Utah Agricultural College the symptoms and injuries caused are described as occurring under Utah conditions. Isolations from over 4,000 roots from diseased plants most frequently yielded *Fusarium orthoceras*, *Rhizoctonia*, *Cylindrocarpon*, *Hainesia*, and *Coniothyrium*. Inoculation tests indicated that *F. orthoceras*, *R. solani*, and *Cylindrocarpon obtusisporum* are capable of inducing typical black rot, and that *Hainesia* may be responsible to some extent. All four are widespread soil fungi. Two obligate parasites in addition to the four pathogenic species named were also found in the cortical layers of the roots, viz, *Olpidium brassicae* and a phycomycetous mycorrhizal fungus.

The possibility of *Ribes* infection by aeciospores of *Cronartium ribicola* at temperatures above 19° C., R. R. HIRT (*Phytopathology*, 27 (1937), No. 1, pp. 103-106).—Fresh aeciospores from *Pinus strobus* bark were placed on solidified aqueous agar in Petri dishes and held between 12° and 30°. Though previous records had indicated 19° as the maximum, germination occurred up to and including 28°. Taking account of the percentage of germination and the germ tube length at 18 hr., it is considered that the possibility of *Ribes* infection from aeciospores is greater at 12° than between 18° and 28°.

Deficiency chloroses in citrus, A. R. C. HAAS (*Soil Sci.*, 42 (1936), No. 6, pp. 435-443, pls. 3).—In this study by the California Citrus Experiment Station, using sand, soil, and solution cultures as media for the orange trees, manganese deficiency was accompanied by a chlorotic spotting of the leaves resembling the symptoms frequently seen in the field under conditions of excessive calcium carbonate. The chlorosis resulting from sulfate deficiency required considerable time for the symptoms to develop and consisted of a general yellowing of the leaf with the veins remaining green until the condition became extreme. In magnesium deficiency the chlorosis at first occurred as a yellow stripe on either side of the dark-green midrib, the leaves later assuming a bronze color.

A deficiency of any of these substances in citrus is accompanied by a more or less characteristic chlorosis, and a knowledge of the symptoms corresponding to certain deficiencies is an aid to the field diagnosis of physiological diseases.

Some new aspects of gummosis and psorosis of citrus trees in Florida, A. S. REARDS (*Fla. State Hort. Soc. Proc.*, 49 (1936), pp. 36-39, pls. 4).—Studies by the Florida Experiment Station indicate that once these diseases have progressed beyond a certain point they frequently become systemic. The discovery of extensive invasion of the wood by *Phomopsis citri* and *Diplodia natalensis* explains why trees with advanced gummosis or psorosis usually fail to respond to the bark-scraping method of treatment. Proper treatment of pruning and other wounds with a suitable and durable dressing would not

only obviate the development of many cases of gummosis having their inception through these channels, but would at the same time prevent the entrance of the organisms of decay.

A new species of *Candelospora* causing decay of citrus fruits, H. S. FAWCETT and L. J. KLOTZ (*Mycologia*, 29 (1937), No. 2, pp. 207-215, figs. 6).—A decay of orange fruit found at Citra, Fla., is shown to be due to *C. citri* n. sp., which is described. Inoculations at the California Citrus Experiment Station indicated the fungus to be capable of causing decay in lemons, oranges, and grapefruit, mature fruit being more susceptible than the immature.

Control of mango blossom-blight and anthracnose, H. E. STEVENS (*Fla. State Hort. Soc. Proc.*, 49 (1936), pp. 125-130).—Copper-lime dust (20-80), a wettable sulfur, and basic copper sulfate were compared in tests with mangoes on the lower east and west coasts of Florida over three seasons. The dust gave very good control under some conditions, but was difficult to handle in practice except when the air was still. Recommendations resulting from this work advocate applications of bordeaux mixture, properly and timely applied, which to a large extent controls blossom blight and anthracnose. From four to five applications usually give good commercial control. The dormant spray is needed as a clean-up treatment and as a protection to the bloom cluster in its early development. The 4-1-50 formula appeared to be as efficient as stronger mixtures.

Some measurements of detrimental effects of the root-knot nematode on the pineapple plant, G. H. GODFREY and H. R. HAGAN (*Phytopathology*, 27 (1937), No. 4, pp. 515-530, figs. 2).—Statistical studies are reported on pineapples grown in the Hawaiian Islands under soil infestation with *Heterodera marioni* over a wide range of intensities. Data taken at 5 mo. of plant growth showed correlations as follows: Root length with gall count as percentage of total roots showing terminal galls—0.60, plant weight with root length 0.76, length of roots with number of roots 0.61, ultimate yield with root length at 5 mo. 0.67, yield with original nematode population as determined by indicator plant readings—0.55. In data taken at 8 mo. of growth in another location the corresponding correlations were lower throughout. Direct gall count in the later reading was completely unreliable as a measure of nematode injury to the plants, with an actual positive correlation of 0.26 between gall count and plant weight. The increased vigor of the heavier plants, derived from escape from early heavy infestation, is indicated as being responsible for a high gall count later, due to increased root surface exposed to infestation in the virtually "nematode-saturated" soil. The same identical population of plants showed a positive correlation of 0.57 between length of roots and plant weight. The root system that developed in spite of nematodes, therefore, is more closely correlated with plant growth in a positive way than is the gall count by any of the criteria tested in a negative way. The multiple correlation of plant weight on the combined factors of root number, root length, and number of galls was 0.72.

Classification of lily-mosaic virus, W. C. PRICE (*Phytopathology*, 27 (1937), No. 4, pp. 561-569, figs. 5).—Three strains of cucumber-mosaic virus transmitted to *Lilium longiflorum* induced symptoms similar to those of lily mosaic. Virus from diseased lilies, obtained from a commercial grower and transmitted to the Turkish variety of *Nicotiana tabacum*, caused primary necrotic lesions and remained localized, producing only an occasional systemic lesion. On passage from tobacco to tobacco, it gave rise to a strain that became systemic and produced mottling symptoms. The latter was transferred to cucumber and to *Zinnia elegans*, in which it produced mottling symptoms. It is known

from previous work that zinnia leaves mottled by cucumber-mosaic virus strains are immune to infection with virus of cucumber-mosaic strain 6, and that infection of zinnia with viruses unrelated to that of cucumber mosaic does not protect them from infection with cucumber-mosaic strain 6 virus. Inoculations demonstrated that zinnia leaves thoroughly invaded by the passage strain of lily-mosaic virus are immune to infection with virus of cucumber-mosaic strain 6. It is, therefore, concluded that lily-mosaic virus should be classified in the cucumber-mosaic virus group.

Cladosporium leaf blotch of peony, L. J. MEULI (*Phytopathology*, 27 (1937), No. 2, pp. 172-182, figs. 3).—Peony leaf blotch (*C. paeoniae*) has been observed on all aerial portions of broadleaf peonies except the blossoms. It is most common among large commercial plantings and is cumulative. The vigor of infected plants is not noticeably diminished, but the dark-purple foliage discoloration frequently detracts from marketability and ornamental value. The range of the disease is limited, since the conidia are disseminated primarily by moisture and infection occurs in the spring. Infection does not occur on the current year's foliage during the growing season. A full description of peony leaf blotch and its causal organism, together with cultural and pathological studies, are offered to facilitate a clearer understanding of the disease.

Of the 10 varieties studied, Oshkosh White, Felix Crousse, and Livingstone proved most susceptible and Gigantea and Humel Carnea most resistant to the disease. Soil and foliage sprays apparently did not reduce infection. Recommended control practices are the destruction of old foliage on which the fungus overwinters and/or transplanting of clean roots to noninfected areas.

Development and succession of forest fungi and diseases in forest plantations, D. V. BAXTER (*Mich. Univ., School Forestry and Conserv. Circ. 1* (1937), pp. 44, pls. 9, figs. 3).—This monograph "reports the results of observations covering a period of several years on the pathology of forest plantations. It lays particular stress (1) on the role played by adverse site factors in predisposing trees to physiological ailments and to attack by fungi, and (2) on the succession of diseases that commonly occurs in plantations as contrasted with natural stands." Studies in the Saginaw and Higgins Lake State Forests, the "Pinetum", and the sand dunes of Michigan included plantation diseases, white pine root rot, diseases of exotic pines, and diseases in fixation plantations.

"In every plantation there is a very definite relation between it as a community and the occurrence of diseases. Ills caused by site alone are apt to be more severe in stands made up of a species which naturally occurs singly than in those composed of gregarious types. A complete system of permanent records, consisting of periodic reports, on representative plantations of different species and mixtures of species on different forest sites and on afterplanting treatments is essential to determine the reasons for successes and failures in plantations."

Relation of oxygen pressure and temperature to growth and carbon-dioxide production in the fungus *Polystictus versicolor*, T. C. SCHEFFER and B. E. LIVINGSTON (*Amer. Jour. Bot.*, 24 (1937), No. 3, pp. 109-119, figs. 4).—"Decay may be expected to be more rapid the more thoroughly the wood is aerated, so long as its water content is adequate to the requirements of the fungus, and the optimal temperature for decay may be expected to be somewhat above the temperature optimum but considerably below the temperature maximum for mycelial growth. It is indicated, for time intervals and wood zones involving a limited range of decay stages, that destruction of wood may be at least rapid in proportion to the spread of infection when relatively low oxygen pressure is accompanied by temperature somewhat lower than the optimum for growth."

ECONOMIC ZOOLOGY—ENTOMOLOGY

Studies of osteology and myology of the beaver (*Castor canadensis*), F. W. YOUNG (*Michigan Sta. Mem.* 2 (1937), pp. 84, figs. 48).—In reporting a study of the bone and muscle structure of the beaver, the osteology is graphically illustrated by plates with accompanying legends. The musculature, which is considered at length (pp. 28–53), gives both detailed descriptions and plate illustrations.

Trapping and transplanting live beavers, L. K. COUCH (*U. S. Dept. Agr., Farmers' Bul.* 1768 (1937), pp. II+18, figs. 15).—The damage caused at times by beavers, as in farming communities or in irrigation or diking districts, or their overabundance may make necessary their removal to carefully selected sites where their dam-building activities may aid in the cause of conservation. The present account gives detailed descriptions of live beaver traps, and discusses trapping operations, holding pens, means and methods of transporting and transplanting trapped beavers, and the selection of proper planting sites.

Adventures in bird protection, T. G. PEARSON (*New York and London: D. Appleton-Century Co.*, 1937, pp. XIV+459, [pls. 8]).—This autobiography, with an introduction by F. M. Chapman, presents information on the history of and personal experiences relating to the advancement of bird protection in America.

Parasites of certain North Carolina Salientia, B. B. BRANDT (*Ecol. Monog.*, 6 (1936), No. 4, pp. 491–532).—The relations of parasitic infestations to the ages, habitats, and habits of frogs and toads are considered, based upon a study conducted at Beaufort County, N. C., the details being given in 15 tables. "Periodic examinations on 71 bullfrogs, 60 southern leopard frogs, 62 Fowler's toads, 60 spadefoots, 55 chorus frogs, and 60 spring peepers were made during the course of a year. Salientians habitually residing in aquatic habitats were more often parasitized with blood protozoans, trematodes, acanthocephalans, and leeches. Seasonal periodicity was observed only in relatively few of the parasites found. Larger, and presumably older, bullfrogs harbored considerably greater numbers of parasites than smaller individuals. Few of the parasites observed occur in a single host. Multiple infestations are common in the salientians studied. As many as 17 species of parasites were found in a single bullfrog. The total number of parasite species distinguished in each of the 6 salientian hosts studied were *Rana catesbeiana* 35, *R. sphenoccephala* 30, *Bufo fowleri* 22, *Scaphiopus holbrookii* 15, *Pseudacris brimleyi* 20, and *Hyla crucifer* 21."

A review of the earlier work is presented with a bibliography of five pages.

A comparative assay of black widow anti-sera, F. E. D'AMOUR (*Soc. Egypt. Biol. and Med. Proc.*, 35 (1936), No. 2, pp. 262, 263).—In a comparative assay of the recently perfected superimmune serum from sheep and a sample of convalescent human serum, the former was found to possess a much higher potency, 1 cc neutralizing 25 average lethal doses of the venomous black widow spider. One cc of human convalescent serum showed no neutralizing power whatever against 2 average lethal doses of venom.

A new apparatus for separating insects and other arthropods from the soil, W. R. S. LADELL (*Ann. Appl. Biol.*, 23 (1936), No. 4, pp. 862–879, pl. 1, figs. 2).—Following a brief review of the published methods, none of which are considered sufficiently rapid or efficient for soil fumigation investigations, a new method devised at the Rothamsted Experimental Station is described.

"The principle of the method is flotation by a dense liquid (a solution of magnesium sulfate sp. gr. 1.11), aided by stirring of the soil and a stream of fine air bubbles passing from the bottom upward through the mixture of soil

and solution. This produces a froth which contains all the animals, and by raising the level of the liquid in the cylinder the froth is swept over into a tank filled with magnesium sulfate solution; here is deposited any soil that has been carried over. The clear solution is then passed on to a Buchner funnel where the insects and other animals are retained. A black filter paper is used in order to show up Collembola and other colorless organisms."

The advantages claimed for the apparatus include rapidity, cleanliness, efficiency, and nontoxicity.

Culture methods for invertebrate animals, P. S. GALTSCOFF, F. E. LUTZ, P. S. WELCH, J. G. NEEDHAM, ET AL. (Ithaca, N. Y.: Comstock Pub. Co., 1937, pp. XXXII+590, figs. 85).—This is a compendium prepared cooperatively by American zoologists under the direction of a committee from section F of the American Association for the Advancement of Science and with the assistance of many specialists whose names appear in connection with their respective contributions. References to the literature accompany many of the articles.

Several contributions from experiment stations, all but one of which relate to economic insects, are Rearing of *Scutigerella immaculata*, by G. A. Filinger, Ohio Experiment Station (p. 259) (E. S. R., 59, p. 462); A Method of Rearing Four Species of Plant Bugs [Green Stinkbug, *Euschistus euschistoides*, *E. variolarius*, and *E. tristigmus*] (p. 299) and A Method of Rearing Two Species of Nabidae [*Nabis roseipennis* and *N. rufusculus*] (p. 306), both by F. G. Mundinger, New York State Station; Culture Methods for the Potato Psyllid [*Paratrioza cockerelli*], by G. F. Knowlton, Utah Station (pp. 317-319); Methods Used in Rearing the Mealybug *Pseudococcus comstocki*, by W. S. Hough, Virginia Station (pp. 329, 330); Notes on Breeding the Oriental Fruit Moth (*Grapholitha molesta*), by W. T. Brigham, Connecticut [New Haven] Station (pp. 345-349); A Method for Studying the Hessian Fly and Other Insects [Chinch Bug, Green Bug, and Corn Leaf Aphid], by J. W. McColloch, Kansas Station (pp. 396, 397) (E. S. R., 46, p. 245); Notes on Breeding the Apple Maggot (*Rhagoletis pomonella*), by P. Garman, Connecticut [New Haven] Station (pp. 436, 437); *Mycotretus pulchra*, by H. B. Weiss, New Jersey Stations (p. 460); *Hippodamia 13-punctata*, by C. R. Cutright, Ohio Station (p. 461) (E. S. R., 53, p. 56); Cissidae, by H. B. Weiss, New Jersey Stations (p. 467); and Methods of Producing *Macrocentrus ancyllivorus* in Large Numbers for Colonization in Peach Orchards, by P. Garman (pp. 493-495), and Methods of Breeding *Peristerola angulata*, a Cocoon Parasite of the Oriental Fruit Moth, by J. C. Schread (pp. 512, 513), both from the Connecticut [New Haven] Station.

Fragments of entomological history, H. OSBORN (Columbus, Ohio: Author, 1937, pp. VII+394, pls. [48]).—The information here contributed, which supplements the historical contributions of Howard (E. S. R., 64, p. 648), Essig (E. S. R., 64, p. 648), and Weiss (E. S. R., 75, p. 305), appears in 12 chapters, as follows: Early steps in entomology (pp. 7-12), the nineteenth century (pp. 13-34), Federal service in entomology (pp. 35-50), State entomologists, inspectors, and quarantine officers (pp. 51-66), experiment station entomology (pp. 67-92), entomological instruction in colleges (pp. 93-120), entomological societies (pp. 121-131), entomological publications (pp. 132-139), personal sketches (pp. 140-236), insect collections (pp. 237-307), some regional notes (pp. 308-326), and miscellaneous notes (pp. 327-334).

Concerning official common names for insects, W. E. BRITTON (Jour. Econ. Ent., 30 (1937), No. 2, pp. 341-345).—Information is contributed on the need and requisites for, the applicability of, and needed changes in the common names adopted by the American Association of Economic Entomologists.

On a new type of respiratory interrelation between an insect (chalcid) parasite and its host (Coccidae), W. H. THORPE (Parasitology, 28 (1936),

No. 4, pp. 517-540, figs. 24).—A study of the biology of the hymenopterous parasite *Encyrtus (Comys) infellæ* (Embleton) of the hemispherical scale, the respiratory relationships with which host are of a quite extraordinary character, is reported.

[Notes on economic insects and their control] (*Jour. Econ. Ent.*, 30 (1937), No. 2, pp. 372-381, fig. 1).—The notes here contributed (E. S. R., 77, p. 65) are as follows: *Thylocdras contractus* Mots. in Texas, by H. J. Reinhard, Texas Experiment Station (p. 372); Methods in Study and Preservation of Leaf-hopper Genitalia, by D. M. Delong and R. H. Davidson (pp. 372-374); Extended Insecticidal Uses of Coal Tar Distillates, by M. H. Doner (p. 374); Dry Pyrocid and Gypsum for Control of the Squash Bug (*Anasa tristis* DeG.), by J. L. Hoerner (p. 375); Some Notes on the Tunneling Habits of *Hylurgopinus rufipes* Eich., by W. B. Becker, Massachusetts Station (p. 375); First Record of *Bathypictes tristis* (Grav.), a Parasite of the Clover Leaf Weevil in the United States (pp. 375, 376) and *Eumicrosoma benefica* Gahan as an Egg Parasite of the Hairy Chinch Bug [*Blissus hirtus* Montd.] (p. 376), both by F. F. Dicke; Effect of Certain Cold-Storage Treatments on Larvae of Cherry Fruitfly, by S. C. Jones, Oregon Station (pp. 376, 377); Sulfated Higher Alcohol to Control Scale Insects on Greenhouse Plants, by E. I. McDaniel (p. 377); Observations on the Life History of *Paratrioza cockerelli* (Sulc.) in Southern California, by A. C. Davis (pp. 377, 378); *Paratrioza cockerelli* (Sulc.) on Tomatoes in Southwest Texas, by M. J. Janes (p. 379); Some Notes on *Bruchus brachialis* Fahraeus, by L. J. Bottimer (p. 379); Strawberry Leaf Roller [*Ancylys comptana fragariae* Walsh & Riley and *Inacampsis fragariella* Busck] Parasites, by G. A. Knowlton, Utah Station (pp. 379, 380); Breaking the Dormancy in the Sugar-Beet Webworm, *L[oxostege] sticticalis* L., by Means of Chemicals, by J. H. Pepper, Montana Station (p. 380); Parasites of Larch Sawfly in Western Montana and Great Lakes Region, by P. B. Dowden (p. 381); and Correction—Methyl Bromide Fumigation of Codling Moth Larvae [E. S. R., 76, p. 501], by D. L. Lindgren (p. 381).

[Report of work in economic zoology and entomology by the Illinois Station] (*Illinois Sta. Rpt. 1935*, pp. 154-182, 260, 261).—Reference is made to the work of the year (E. S. R., 74, p. 512), by W. P. Flint, W. P. Hayes, G. H. Dungan, J. H. Digger, F. C. Bauer, M. D. Farrar, J. R. Holbert, L. H. Shropshire, J. J. Jieper, S. C. Chandler, E. R. McGovran, C. C. Compton, W. E. McCauley, W. A. Foster, E. W. Lehmann, A. S. Colby, and R. S. Marsh, with the European corn borer, chinch bug control, resistance of corn hybrids to the corn earworm, a search for an improved fumigant for stored corn, the control of webworms attacking alfalfa and cutworms and armyworms attacking the soybean crop, improved cutworm bait made with lubricating oil, reduction of hessian fly infestation of wheat in 1934, the value of liquid paradichlorobenzene in peach borer control (E. S. R., 76, p. 76), observations of the plum curculio on peach, parasites as a promising means of controlling the oriental fruit moth, introduction of parasites for insect pests, the value of new oil dusts for control of peach insects, the relation of soil-building legumes to the peach insect control problem, the increased effectiveness resulting from the combination of lead arsenate and oil in the place of lead arsenate alone, lack of variation in efficiency of brands of lead arsenate, reduction in injury from San Jose scale resulting from an orchard survey, the value of cryolite in checking damage by the apple flea weevil, oil sprays safe for Illinois orchards, control of the apple borer by paradichlorobenzene in oil, importance of avoiding the use of worthless insecticides, mites as serious enemies of raspberry, thrips as related to the set of strawberries, destruction of the gladiolus thrips on corms in storage, control of leaf rollers and tiers by the use of

pyrethrum, destruction of earthworms in greenhouses by hydrated lime, superiority of steam over hot water in the destruction of nematodes in greenhouses, dusting with sulfur for the control of the broad mite in greenhouses, control of red spiders through dusting with powdered glue, increased abundance of the European elm scale, control of the oystershell scale, control of the privet thrips *Dendrothrips ornatus* Jab. by application of nicotine-pentrol or nicotine-soap spray, crude naphthalene for control of fleas, locust borer control, thallium sulfate as a means of ant control, termite control through treatment of wood with certain combinations of chemicals, protection of clothing in storage by insecticides, value of light and bait traps in insect forecasts, and reduction of mite injury of raspberries by application of oil sprays.

[Work in economic zoology and entomology by the Indiana Station] (*Indiana Sta. Rpt. 1936, pp. 35-40, 47, figs. 3*).—Reference is made (E. S. R., 75, p. 806) to work with the European corn borer, cutworms, corn earworm, chinch bug, tarnished plant bug, cucumber beetles, oriental fruit moth, codling moth (including field insecticide tests, sanitation, spray residue, and light traps), Japanese beetle, hessian fly, white grubs, and winter survival and nesting studies with quail.

[Contributions on economic insects and their control] (*Iowa State Hort. Soc. Rpt., 70 (1935), pp. 10-12, 13-16, 21-24, 45-50, 289-291, 341-350, figs. 16*).—Contributions relating to economic insects, presented at the annual meeting of the Iowa State Horticultural Society and of the affiliated societies in 1935 (E. S. R., 74, p. 366), are Observations on the Apple Maggot in 1935, by C. H. Richardson and T. R. Hansberry (pp. 10-12), and Codling Moth Bait Trap Records, 1935 (pp. 13-16), and Apple Leaf Insects, Including Leaf Hoppers, Red Spiders, and Leaf Miners (pp. 21-24), both by T. R. Hansberry and C. H. Richardson, Iowa Experiment Station; Some Problems in the Control of Small Fruit Pests, by A. S. Colby (pp. 45-50); The Mexican Bean Beetle in Iowa, by C. J. Drake (pp. 289-291), and Results of 1935 [Bee] Disease Resistance Program, by O. W. Park, Iowa Station (pp. 341-350), referred to on page 373.

[Abstracts of entomological theses] (*Iowa State Col. Jour. Sci., 11 (1936), No. 1, pp. 23-25, 48-53, 57-65, 72-74, 121-124*).—Abstracts of doctoral theses here presented include The Firebrat, *Thermobia domestica* (Packard), and Its Gregarine Parasites, by J. A. Adams (pp. 23-25); The Animal Parasites of the Woodchuck (*Marmota monax* L.) With Special Reference to Protozoa, by H. B. Crouch (pp. 48-50); a Toxicological Investigation of Nicotine on the Goldfish and the Cockroach, by L. O. Ellisor (pp. 51-53); On the Penetration of Certain Arsenical Compounds Into the Body of the American Cockroach, *Periplaneta americana* (L.), by L. C. Glover (pp. 57-59); An Investigation of the Penetration of Pyridine, Piperidine, and Nicotine Into the Bodies of Insects, by L. H. Glover (pp. 60-62); Investigation of Codling Moth Populations as They Affect Control Experiments, by T. R. Hansberry (pp. 63-65); The Value of Several Organic compounds as Contact and Stomach Poisons for Certain Insects, by J. F. Kagy (pp. 72-74); and Studies on Insect Hemolymph With Special Reference to Some Factors Influencing Mitotically Dividing Cells, by O. E. Tauber (pp. 121-124).

[Work in entomology by the Tennessee Station] (*Tennessee Sta. Rpt. 1936, pp. 41-43, 66, 67, figs. 3*).—Reference is made (E. S. R., 76, p. 65) to cryolite as an insecticide for use on tobacco (E. S. R., 76, p. 825), cottonseed meal as a bait for control of the corn earworm, cryolite as a substitute for lead and arsenic, and the more important insect pests of the year (including the variegated cutworm, cabbage aphid, cotton or melon aphid, cotton leaf worm,

and the fall armyworm), all by S. Marcovitch, and codling moth bait trapping, by L. A. Fister and B. D. Drain.

[Work in economic entomology by the Washington Station] (*Washington Sta. Bul.* 342 (1936), pp. 22, 23, 32, 33, 66, 67).—The work of the year briefly referred to (*E. S. R.*, 75, p. 79) includes chemical studies of insecticides, by K. Groves; oils in combination with lead arsenate and nonarsenicals and nonlead arsenicals for codling moth control, by R. L. Webster and J. Marshall; the pea moth, by A. J. Hanson and Webster; effect of fatty acids on arsenical sprays, by Marshall; and codling moth activity, by Webster. Work at the Cranberry-Blueberry Substation, by D. S. Crowley, included scale control with insecticides, fireworm control, and fruitworm observations.

Experiments on control of insects of tobacco, 1936, A. W. MORELL, JR., and D. S. LACROIX (*Connecticut [New Haven] Sta. Bul.* 391 (1937), pp. 84-98, figs. 6).—Experiments, particularly with the potato flea beetle, conducted cooperatively with the U. S. D. A. Bureau of Entomology and Plant Quarantine, commencing on June 2, 1936, and continuing during the summer, are reported (*E. S. R.*, 76, p. 214), the details being given in eight tables.

In the experimental control work with the potato flea beetle in shade tents, barium fluosilicate, cube root powder (4 percent of rotenone), and sodium aluminum fluosilicate were diluted with sterile tobacco dust. Cube root powder and tobacco dust showed the highest number of dead beetles and the next to the least total leaf injury.

In control experiments with Havana Seed tobacco, comparisons were made of the effectiveness of dust mixtures consisting, respectively, of 1 percent of rotenone, barium fluosilicate diluted with tobacco dust 1 to 3 by volume, cube root powder (1 percent of rotenone) and barium fluosilicate mixed in equal parts with no tobacco dust, and a proprietary mixture containing 0.55 percent of rotenone. There was very little difference in the effectiveness of these materials, which were applied July 18, July 25, and August 3, respectively, following an increase in beetle population that began about July 15, but all showed a distinct improvement over the untreated check. The dust residue on the leaves was not objectionable except on the plot treated with barium fluosilicate and 1 percent of rotenone dust.

Population counts made in observations of the resistance of tobacco indicate that the types known as No. 211 and shade strain D are somewhat resistant to attack by the potato flea beetle.

In a study of the dispersal of the flea beetle, screens covered with adhesive material were erected and captured beetles counted every second day. The beetles seemed definitely to fly from potatoes to the Havana Seed tobacco and to the shade tent, with a marked preference for the latter.

In emergence studies flea beetles were found to appear in the fields in large numbers about the middle of June. The summer brood was very slow in emergence, the peak occurring about July 23 and continuing through the first week in August.

Shade tobacco is said to have been dusted regularly at about 6-day intervals by nearly all growers with a dust containing from 0.67 to 0.83 percent of rotenone, and this apparently prevented any considerable damage by the flea beetles.

Sunflowers planted by one grower as shade in alternate rows with his Havana Seed tobacco as counter-attractants for the beetles, proved definitely attractive. The sunflowers were riddled by the beetles while the tobacco showed little or no damage, and not many beetles were found resting on the tobacco although the sunflower leaves were heavily populated.

The use of power machinery during the summer in the application of poison dusts for flea beetle control resulted in very even distribution of the dust, due to the high velocity of delivery and the swirling motion as the dust leaves the machine. The efficiency of the power duster was proved by the great reduction in flea beetle injury and the coverage of a large acreage in a short time.

Reference is made to the use of several contact insecticides in combating the tobacco thrips, the details of which are tabulated. None of the materials tested, which included lauryl thiocyanate, nicotine sulfate, pyrethrum extract, and cube root powder, proved satisfactory at the strengths used.

Reference is also made to the abundance of the various species of insects on tobacco during the year, including the eastern field wireworm, red-legged grasshopper, lesser migratory locust *Melanoplus mexicanus mexicanus* Sauss., the Carolina grasshopper, dark-sided cutworm, stalk borer, tobacco worm, and tomato worm.

The pests of fruits and hops, A. M. MASSEE (*London: Crosby Lockwood & Son, 1937, pp. 294, pls. [27]*).—The need for an up-to-date work on fruit insects in Great Britain to replace that of Theobald, published in 1909 (E. S. R., 21, p. 655), led to the preparation of this handbook. The insect and other animal pests are considered by host fruits in alphabetical order, followed by chapters on hop pests, beneficial and harmless insects, and insecticides, and on spraying equipment and methods by J. Turnbull. Indexes to scientific and common names and to authors are included.

The animal parasites of domestic and useful animals, and of man, J. FIEBIGER (*Die tierischen Parasiten der Haus- und Nutztiere, sowie des Menschen. Berlin and Wien (Vienna): Urban & Schwarzenberg, 1936, 3. ed., rev., pp. XII+374, pl. 1, figs. 352*).—A revised edition of this work (E. S. R., 49, p. 377). A systematic list of the parasites of domestic and useful, fur-bearing, and laboratory animals, and of man, with their hosts indicated, and a host list of the parasites, with their habitat in or on the hosts, are included.

Household pests: Their habits, prevention, and control, P. B. COLLINS (*London: Isaac Pitman & Sons, 1936, pp. XIII+98, figs. 6*).—A practical account.

Method for determining amount of mineral oil deposited on orange leaves immediately after spraying, V. J. TIHENKO and G. S. HENSILL (*Jour. Econ. Ent., 30 (1937), No. 2, pp. 355-360, fig. 1*).—An account is given of a method for determining the amount of oil deposited on orange leaves. This is considered of particular advantage due to its being rapid, since determinations of oil can be started before the spray has dried. It has been proved that acetone U. S. P. is an efficient solvent for use in this method. Providing careful technic is maintained, no amount of oil of significant importance is lost during any of the various parts of the procedure. It is pointed out that a sulfonation curve for determining the amount of oil in sulfonation bottles must be constructed for the determination of each oil by this method.

The relative quantities of oil deposited upon paraffin-coated plates and upon plant foliage by oil sprays, L. H. DAWSEY, A. W. CRESSMAN, and J. HILEY (*Jour. Agr. Res. [U. S.], 54 (1937), No. 5, pp. 387-398, figs. 3*).—Studies undertaken in an effort, first, to develop a suitable technic capable of giving reproducible plate deposits, and then to determine whether a definite proportionality exists between the quantities of oil retained by the plate surfaces and a selected plant surface, are reported. Included in the report, the details of which appear in tables and graphs, is a description of a method for spraying paraffin-coated mica plates with oil emulsions and determining the quantities of oil deposited by difference in weight.

"Comparison between the quantities of oil deposited on the paraffin surfaces of the plates and those deposited on chrysanthemum foliage, as deter-

mined by chemical analysis, showed that various emulsions give different ratios of plant deposit to plate deposit. It is therefore not practical to attempt to standardize the sprays intended for the plant surface against the plate surface. Within certain limits of error, emulsions containing glue, ammonium caseinate, or bentonite gave characteristic ratios of plant deposit to plate deposit which were independent of the oil concentration or the emulsifier concentration in the dilute sprays, but with soap emulsions these ratios varied with the concentration of oil and emulsifier."

The problem of the evaluation of rotenone-containing plants, II, III (*Ann. Appl. Biol.*, 23 (1936), No. 4, pp. 880-916, figs. 6).—The second contribution in this series (E. S. R., 74, p. 605) from the Rothamsted Experimental Station, by J. T. Martin and F. Tattersfield, deals with *Derris elliptica*, *D. malaccensis*, and the "Sumatra-type" roots (pp. 880-898); part 3 relates to a study of the optical activities of the resins of these roots by F. Tattersfield and J. T. Martin (pp. 899-916).

Control of wireworms and onion thrips by carbon bisulfide carrying naphthalene or PDB, B. B. PEPPER (*Jour. Econ. Ent.*, 30 (1937), No. 2, pp. 332-336).—In control work by the New Jersey Experiment Stations with wireworms, which are among the most important pests of cabbage, cauliflower, horseradish, beets, and several other vegetables in the market garden area of the northern counties of the State, "emulsions containing $\frac{1}{4}$ oz. of carbon bisulfide and 1 g of either PDB or naphthalene per plant gave an average of better than 80 percent kill of wireworms. Carbon bisulfide alone at the rate of $\frac{1}{4}$ oz. per plant was ineffective and caused plant injury, while 1 g of PDB in cottonseed oil emulsion gave a 55-percent kill and was apparently safe on plants. Aresklene emulsions of carbon bisulfide appear to be more effective than those made with sulfonated castor oil. The cheapest combination used was carbon bisulfide-crude chipped naphthalene. Carbon bisulfide-naphthalene emulsion was more effective than nicotine sulfate-soap against onion thrips."

Experiences with the termite in New Jersey, T. J. HEADLEE (*Jour. Econ. Ent.*, 30 (1937), No. 2, pp. 337-341).—Notes are contributed from the New Jersey Experiment Stations on the habits under natural conditions and in wooden structures and the means of prevention and control of *Reticulitermes flavipes*, the only species of termite received or taken by the stations.

Periodical cicada control in Michigan for 1936, E. I. McDANIEL (*Michigan Sta. Quart. Bul.*, 19 (1937), No. 3, pp. 144-146, figs. 2).—The periodical cicada, which made its appearance in 1936, was restricted in its occurrence in Michigan, with few exceptions, to open stands of hickory and oak in the lower two tiers of counties within which areas an occasional orchard or nursery or block of transplants was attacked. Few, if any, cicadas were found present on land known to have been infested but which had been subjected to intensive cultivation for several years before planting.

Several hundred nymphs sifted from the soil were sprayed in the laboratory with different dilutions of various contact insecticides without killing any of the immature underground forms. In laboratory tests aliphatic thiocyanates applied 1:20 killed the adults, a satisfactory commercial kill being effected with a 1:100 dilution. Three common contact insecticides, (1) thiocyanates plus light petroleum oil or plus spreader, (2) 40-percent nicotine sulfate plus soap, and (3) pyrethrum, were applied in an infested orchard as the first adults appeared, the results being reported in table form. It was found practical to knock the cicadas off the trees with either thiocyanate 1:150 or pyrethrum 1:150 and to follow up with a blowtorch, killing those that survived after a period of from 10 to 12 hr. Where this treatment was not feasible an application of 40-percent nicotine sulfate 1:400 plus soap gave a satisfactory com-

mercial kill. Many eggs were laid in portions of the orchard where no sprays were applied or where the females emerged after the males were killed. Trees previously untreated were sprayed with 0.75 pt. 40-percent nicotine sulfate plus 1.5-percent summer oil to 100 gal. of water, and fewer than 5 percent of the eggs in trees hatched.

Observations on brood X of the periodical cicada in Maryland, H. N. COAY and P. KNIGHT (*Jour. Econ. Ent.*, 30 (1937), No. 2, pp. 287-294).—This contribution consists of class reports and observations of staff members of the University of Maryland, made during the fall of 1935 and spring of 1936 and summarized by the authors.

A biological study of *Lygaeus kalmii* Stål (Hemiptera-Lygaeidae), W. A. SIMANTON and F. ANDRE (*Bul. Brooklyn Ent. Soc.*, 31 (1936), No. 3, pp. 99-107, figs. 7).—Observations of the biology of this large lygaeid in Iowa, together with a description of its life stages, are presented. Approximately 80 percent of the adults of this insect collected in the field during July and August 1935 were parasitized by a tachinid fly of the genus *Leucostoma*.

Leafhopper control on grapes, R. HUTSON (*Michigan Sta. Quart. Bul.*, 19 (1937), No. 3, pp. 142-144).—Although eggs at hatching time and the nymphs are killed by nicotine, varied results have attended the use of this insecticide, largely because of the difficulty experienced in accurately timing applications to coincide with the time when all the eggs were laid but before any of the nymphs acquired wings. Some experimental control work during the seasons of 1935 and 1936 with nicotine and other sprays confirmed the view that nicotine does not have much effect upon the adult. That a careful watch be kept for hatching and the sprays applied at that time is emphasized by the results obtained. This method of combating grape leafhoppers was tested during the season of 1936, county agents in the grape-growing areas having been kept informed as to the proper time for spray application. As a result better grape leafhopper control was obtained than for many years. The nicotine sprays applied for such control should contain 1 pt. of 40-percent nicotine per 100 gal. of spray and some spreader.

Reactions of aphids to colored insecticides, J. B. MOORE (*Jour. Econ. Ent.*, 30 (1937), No. 2, pp. 305-309, figs. 2).—It was found in work at the New York State Experiment Station that the green peach aphid is attracted to potato plants when they are sprayed with bordeaux because of the increased intensity of light reflected from the sprayed surfaces. The insects appear to follow the inverse-square law of light intensities, thus showing that light intensity is the primary factor involved in attracting the aphids to the sprayed surfaces. It was also found that infestations of the cabbage aphid on dusted plats could be reduced below those on untreated plats by dyeing the dusts used. Black dust was the most effective in reducing the infestation. These experiments suggest that present dusting and spraying practices on crops infested with aphids may be profitably modified by the use of dyed materials to produce a reduction in the intensity of light reflected from the treated surfaces.

Growth, reproduction, feeding, and wing development of the mealy plum aphid in relation to climatic factors, L. M. SMITH (*Jour. Agr. Res. [U. S.]*, 54 (1937), No. 5, pp. 345-364, figs. 9).—In studies conducted at the California Experiment Station, the details of which are given in tables and graphs, a high correlation was found to exist between the rate of development of the mealy plum aphid and daily mean temperature, and formulas for the determination of the rate of development per day at any mean temperature are presented. The four instars were found to be of approximately equal duration at any given mean temperature. "The correlation between number of young born and daily mean temperature ranged from 0.54 to 0.75 under varying con-

ditions. Rate of reproduction was shown to be related to age of females, which in turn was influenced by temperature. The rate of feeding was related to temperature, and it was found that the rate of feeding did not increase as rapidly as the rate of reproduction for a given increase in temperature. This results in the relative starvation of young born at higher temperatures and is offered as an explanation of wing determination."

A list of 23 references to the literature cited is included.

Do fungi help to exterminate red scale in Palestine? J. CARMIN (*Hadar*, 9 (1936), No. 8, pp. 173-175, figs. 7).—A preliminary account of observations which are considered to show clearly the value of fungi in the extermination of the California red scale in Palestine.

Further tests with pyrethrum as an insecticide for cabbage worms, H. C. HOOKER (*Jour. Econ. Ent.*, 30 (1937), No. 2, pp. 323-328).—Experiments conducted at Riverhead, Long Island, in continuation of earlier work (E. S. R., 75, p. 667), on the effectiveness of pyrethrum dust mixtures when used in the insectary against the young larvae of the zebra caterpillar and for the control of the cabbage looper under field conditions, are reported. The work was conducted with a view to determining what strength of pyrethrum dust mixture might be most effective for commercial purposes and what diluent, if any, might prove to be more satisfactory than others when mixed with the more heavily impregnated pyrethrin powders. "Three types of pyrethrum products were tested, namely, ground pyrethrum flowers of 0.9 and 0.6 percent pyrethrin analysis, an inert material impregnated with the extractives of pyrethrum flowers to carry 2 percent pyrethrin content, and pyrethrum powders impregnated to carry a pyrethrin strength of 0.5 percent. Four inert materials were tried as diluents, namely, clay, talc, gypsum, and infusorial earth. The most notable features of the results in respect to the factors of pyrethrin strength in the finished dust and type of diluent were the greater effectiveness of dusts having a stock pyrethrum powder of lower pyrethrin analysis as compared with a higher analysis, and the diminished effectiveness of dusts having clay as the diluent in comparison with those containing talc, gypsum, or infusorial earth."

A recent pest of alfalfa, L. O. ELLISON and L. T. GRAHAM (*Jour. Econ. Ent.*, 30 (1937), No. 2, pp. 278-280).—This contribution from the Louisiana Experiment Station relates to the velvet bean caterpillar, which was a serious pest of alfalfa in southern Louisiana during the late summer and fall of 1936. The egg parasite *Trichogramma minutum* and a parasitic fungus, *Spicaria prasina*, were factors in reducing the infestation in some areas. At present, its combat is limited to poison control on fall seedlings and to the delay of fall plantings to prevent defoliation of the seedlings by the caterpillars.

Earlier accounts of this caterpillar as a pest of soybeans in Louisiana by Hinds and in Louisiana and Texas by Douglas (E. S. R., 64, p. 54) have been noted.

Biology and control of the juniper webworm in Maryland, G. S. LANGFORD (*Jour. Econ. Ent.*, 30 (1937), No. 2, pp. 320-323).—An account is given of the biology and seasonal history, natural enemies, and control of *Dichomeris marginellus* Fab. This webworm, which appeared as an injurious insect in Maryland in 1931, has since spread quite generally over the State, and is now the most injurious insect in the State attacking juniper, including *Juniperus communis* and the varieties *depressa*, *depressa aurea*, *hibernica*, and *suecica*. Other species of juniper, even when adjacent to *J. communis*, have not been observed to be attacked. The webworm, of which there is but one brood a year, passes the winter as partly grown larvae in silken cases within the webbed foliage. Some larvae, depending on the season, may pupate as early as April 25, others as late as June 27. The greatest number of pupae are

usually found in the field between May 22 and June 1. The pupal period varied from 10 to 20 days, with an average of about 16 days. Adults have been observed to emerge as early as May 19 and as late as July 7. The peak of emergence normally takes place between June 1 and June 10. It is attacked by the straw itch mite and several hymenopterous parasites, including *Horismenus microgaster* Ashm., which was frequently found emerging from larvae. The parasites *Dibrachys catus* Walk., *Ephialtes aequalis* (Prov.), *Itoplectis conquisitor* (Say), and *Habrocytus* sp. were reared from the pupae.

Control tests have indicated that arsenate of lead applied as a spray without a spreader is an efficient remedy. "In a series of tests spraying with arsenate of lead, 2 lb. in 50 gal. of water, at approximately monthly intervals from July 1 to October 1 and from March 1 to May 1 gave an average kill of 97.2 percent. Sprays applied between May 1 and May 20 were not as effective, because too many larvae had finished feeding and were in the process of transformation. However, arsenate of lead applied during that period, or even much earlier in the spring, is quite effective in preventing injury by the new generation. Because of its residue, arsenate of lead proved to be superior to pyrethrum and rotenone sprays. . . .

"When used at dilutions sufficiently strong and care was taken to wet all larvae with the solution, pyrethrum soap sprays applied between July 1 and October 1 and between March 1 and May 1 appeared to give as good a kill as arsenate of lead. The material used contained about 2 percent pyrethrins and gave an average kill of 97.3 percent at a dilution of 1:200 and 96.4 percent at a dilution of 1:400."

A dust of either undiluted arsenate of lead or calcium arsenate was found to be effective "if applied during summer or early fall. Diluted arsenate of lead was not promising. One test made early in April, using arsenate of lead, diluted 1 part in 6 parts of 300-mesh sulfur, was not effective. After 21 days only 68.4 percent of the larvae were dead. Two tests, one in the spring and another during late summer, made with a 60-percent pyrethrum dust, gave 79.6 percent kill for the spring application and 94.4 percent for the summer application.

"Results obtained with rotenone dusts have been variable. The best kill, 73.3 percent, was obtained with a 0.75-percent rotenone dust applied during late summer."

Notes on a cacao pod borer moth, *Acrocercops cramerella* Snell, F. Q. OTANES (*Philippine Jour. Agr.*, 7 (1936), No. 4, pp. 419-423, pls. 2).—Notes are given on *A. cramerella*, a lepidopterous enemy of cacao in Java, which was observed by the author first in the field at Mulig, Davao, P. I., in May 1932 and again in May and June 1936, and which has appeared at other points. It has been found in Davao somewhat widespread, as high as 90 percent of the pods in the cacao-growing districts being usually destroyed.

The toxicity of combinations of nicotine, under Michigan conditions, to the tree and to the codling moth (*Carpocapsa pomonella* Linn.), J. M. MERRITT (*Michigan Sta. Tech. Bul.* 154 (1937), pp. 47, figs. 9).—Following a brief introduction, a review of the literature with a list of 34 references, and a discussion of the experimental theory and objectives, experiments conducted in 1934 and 1935 are reported. The findings, the details of which are given in 23 tables, led to the conclusion that the use of nicotine in cover sprays as the active principle is entirely satisfactory for codling moth control provided the interval between sprays does not exceed the period of toxicity of each application. It supplies a substitute insecticide for inclusion in the spraying program of growers who find it impractical to attempt removal of arsenical or lead

residues. No environmental effects were encountered in either of the 2 yr. which prevented some degree of control with any material tested. It is pointed out that the data are too limited to make this a definite characteristic, for some materials have been found ineffective elsewhere under conditions which might be expected to occur in Michigan.

"It has been shown that it is possible to modify the nicotine volatilization by certain combinations, and that the deposition of nicotine by each spray is proportional to the control of codling moth, except when materials used in modification are in themselves insecticides.

"A definite effect of sprays applied to the foliage and fruit has been demonstrated, the toxicity resulting either from some components of the combinations applied, as in the case of sulfur, or oil in the oil-nicotine combination, or from the resultant combination as in the case of Nico-Zin-oil, or by the position in the schedule of different materials, as in the case of oil following sulfur applications. The complete elimination of injury is also possible as in the case of the bentonite-nicotine combinations used in 1935.

"These experiments indicate that no more practical nicotine combination than summer oil and nicotine sulfate was tested. Control of both types of codling moth injury and production of satisfactory quality fruit was best achieved by this material. However, other materials will give either better codling moth control, or less injury, or better quality fruit, or higher photo-synthetic activity, with resultant increase in quality, or longer retention of toxicity."

Experiments with calcium arsenate to control codling moth, B. F. DRAIGS (*Jour. Econ. Ent.*, 30 (1937), No. 2, pp. 314-319).—In work at the new Jersey Experiment Stations calcium arsenate "was compared pound for pound with lead arsenate in a schedule with summer oil used three times on first brood and once on second brood in a Glassboro orchard heavily infested with codling moth. Approximately twice as many larvae succeeded in entering the apples on the plat sprayed with calcium arsenate as on the plat sprayed with lead arsenate, even though the arsenic deposit on the two plats was approximately equal. The inferiority of the calcium arsenate was further brought out by the fact that a plat sprayed with lead arsenate-oil for first brood, but which received no second-brood sprays, had no more worm entries than the calcium arsenate plat which received the same number of first-brood sprays plus second-brood sprays.

"At Moorestown calcium arsenate was compared to lead arsenate in the lime-milk schedule. Approximately eight times as many larvae gained entrance to the fruit sprayed with calcium arsenate-lime-milk as gained entrance to the fruit sprayed with lead arsenate-lime-milk. A plat sprayed with lead arsenate-lime-milk first brood only and a plat sprayed with lead arsenate-oil first brood only had fewer worm entries than the calcium arsenate-lime-milk plat sprayed for both the first and second broods.

"It is suggested that the superiority of lead arsenate over calcium arsenate as a spray for codling moth may be due to the superior physical properties of the lead arsenate over the calcium arsenate."

Experimental break of the diapause of the codling moth [trans. title], A. BALACHOWSKY (*Compt. Rend. Acad. Sci. [Paris]*, 204 (1937), No. 4, pp. 294, 295).—The author finds that a break in the diapause of the codling moth, upon completion of their growth (fifth larval instar), is obtained through exposure of the larvae to a low temperature followed immediately by transfer and maintenance at a high temperature, the resulting break being caused by the sudden thermal shock.

Egg and larval populations of European corn borer in relation to time of planting and yields of sweet corn, M. SCHLOSBERG and R. MATHES (*Jour. Econ. Ent.*, 30 (1937), No. 2, pp. 280-287).—In studies made in 1934, 1935, and 1936 in northern Ohio satisfactory protection from European corn borer infestation and favorable corn yields were obtained under single-generation conditions in plantings made from the first week in June to the first week in July. "In 1936 a partial second generation of moths reduced the protection otherwise gained by late planting. Late-planted corn was more severely infested by the corn earworm (*Heliothis obsoleta* Fab.), but consequent injury of the ears was not reflected in the yield of cut corn for canning. In an evaluation of the economy of late planting to reduce borer infestation the market gardener must consider the relatively higher prices prevailing early in the season, while the canner is concerned with factory operation, labor costs in handling the ears, and danger of contamination of the canned product."

Resistance of a single-cross hybrid strain of field corn to European corn borer, L. H. PATCH (*Jour. Econ. Ent.*, 30 (1937), No. 2, pp. 271-278, fig. 1).—A study of the comparative borer resistance of two single-cross hybrid strains of corn of about equal seasonal requirements that were infested naturally by the European corn borer in 1936 is reported. One of the strains, III. R4 × III. Hy, had shown a relatively high degree of borer resistance during several seasons when infestations were induced by placing eggs on the plants by hand, whereas the other strain, III. A × Ind. Tr, had proved to be borer susceptible when tested by similar methods. The borer-resistant strain has also given promise as a high-yielding strain, the 14 plantings made of it from 1931 to 1935, inclusive, yielding an average of 9 bu. per acre more than the mean yield of all the strains in the tests.

The number of borers reaching maturity in 10 plantings of R4 × Hy made in 1936 was equal to 46.6 percent of the number in A × Tr. The numbers of egg masses laid on the strains were about the same. It is considered improbable that the small differences noted between the strains in leaf area and stage of plant development accounted for the large differences in final borer populations. Past experiments indicate that the borer resistance of single-cross strain, R4 × Hy, compared with local open-pollinated varieties Clarage and Woodburn would be about the same as when the comparison is with single-cross strain, A × Tr.

Experiments on the resistance of the flour moth (*Ephestia kühniella* Zell.) to abnormally high temperatures, G. H. MANSBRIDGE (*Ann. Appl. Biol.*, 23 (1936), No. 4, pp. 803-821, figs. 4).—The resistance of the Mediterranean flour moth to high temperatures is reported upon. When exposed to 113° and 116° F., 1-day-old eggs are more resistant than older eggs. "Eggs are more resistant to heat at low than at high humidities. Eggs appear to be able to cool themselves at low humidities in a high temperature by the evaporation of water. After heating, eggs can regain water they have lost if they are kept in a moist atmosphere. After heating at low humidities, there is a bigger survival if the eggs are kept in a moist atmosphere than if they are kept in a dry atmosphere. There is a great variation in stock from a mill. Eggs from different pairs of moths may have widely different degrees of resistance. Stock which has been inbred in the insectaries for 12 generations shows less variation in resistance than stock direct from a mill. Larvae are much less resistant than eggs. Newly hatched larvae and all larvae until they are full grown have about the same resistance. Last-stage larvae are far more resistant than other larvae. Pupae are more resistant than feeding larvae. Adults are the most susceptible stage to heat. At low humidities the females are more resistant than the males.

"Experiments on all stages in undisturbed cultures show that a temperature of 45° to 46° C., maintained for 3 hr., kills all stages."

Reaction of corn ear worm moth and other insects to light traps, L. A. CARBUTH and T. W. KERR, JR. (*Jour. Econ. Ent.*, 30 (1937), No. 2, pp. 297-305, figs. 3).—Three types of light sources in electrocuting traps were tested by the New York State Experiment Station against female moths of the corn earworm in cornfields on western Long Island during 1936 in attempts to reduce larval infestations in sweet corn. "The numbers of moths caught were directly influenced by mean night temperatures. A seasonal variation in numbers of moths caught was observed which corresponded with expected periods of moth abundance. Two types of mercury vapor light sources each attracted more corn earworm moths than did a 75-w tungsten light source, although fewer females were caught than males. It may be questioned whether any of the traps used were fully effective in attracting female moths of the corn earworm. No appreciable reduction in larval infestations resulted from any of the traps used. Incidental observations are reported on the reaction of Asiatic garden beetles and moths of the European corn borer to the light traps."

Some facts underlying the attraction of mosquitoes to sources of radiant energy, T. J. HEADLEE (*Jour. Econ. Ent.*, 30 (1937), No. 2, pp. 309-312).—The results obtained by the New Jersey Experiment Stations in an investigation of the relationship existing between certain sources of radiant energy known to be attractive to mosquitoes and the number of mosquitoes caught under the same set of environmental conditions are reported.

Four of the New Jersey mosquito traps were set up, the sources of radiant energy employed being as follows: Trap 1, a 25-w white-frosted bulb, giving a white light, under the hood; trap 2, a tube filled with neon gas, giving a red light; trap 3, a tube filled with mercury vapor and so stained as to give a green-yellow light; trap 4, a tube filled with mercury argon vapor and unstained, giving a blue light. The vapor-filled tubes when subjected to high voltage blazed with light running through red, green-yellow, and blue. The tabulated results show that the "attraction power of the red light as measured in number of mosquitoes caught per microwatt is 6.1 times the number that would have been taken per microwatt in white light in trap 2, that the number of mosquitoes taken per microwatt in green-yellow is 12.3 times as many as would have been taken per microwatt with white light in trap 3, and that the number of mosquitoes taken per microwatt in blue light is 21.5 times as great as would have been taken per microwatt in white light in trap 4."

Earlier work (E. S. R., 68, p. 789) has convinced the author that the 25-w white-frosted bulb does not produce an intensity even approaching that point on the curve of reaction where attraction turns to repellency.

Studies in reducing volume of oil necessary to kill mosquito larvae by incorporating pyrethrum, J. M. GINSBURG (*Jour. Econ. Ent.*, 30 (1937), No. 2, pp. 328-332).—In research at the New Jersey Experiment Stations, experiments were conducted in the laboratory with kerosene containing different percentages of pyrethrins on two species of mosquito larvae (the salt-marsh mosquito and *Culex pipiens*) "with the purpose of ascertaining the smallest quantity of pyrethrins which will increase the toxicity of kerosene to the extent that the minimum volume of oil by which it is physically possible uniformly to cover a given area of water should at the same time also produce a toxic film to mosquito larvae. The results suggest that the toxicity of kerosene to mosquito larvae can be increased four times by incorporating 0.01 to 0.04 percent actual pyrethrins, thereby reducing the volume of oil required to cover an acre of water surface under laboratory conditions from 12 to 3 gal."

Toxicity of phenothiazine derivatives to culicine mosquito larvae, P. S. SCHAEFFER, H. L. HALLER, and D. E. FINK (*Jour. Econ. Ent.*, 30 (1937), No. 2, pp. 361-363, fig. 1).—In the work reported 11 derivatives of phenothiazine were tested against culicine mosquito larvae to determine the effect of substituents in a molecule known to possess high toxicity; 6-methylphenothiazine was one-half as toxic as phenothiazine, and all the other derivatives were even less toxic.

Sheep blow-fly investigations, III, IV, R. P. HOBSON (*Ann. Appl. Biol.*, 23 (1936), No. 4, pp. 845-861).—Two further contributions (*E. S. R.*, 74, p. 670) are presented:

III. *Observations on the chemotropism of Lucilia sericata* Mg. (pp. 845-851).—The attraction for *L. sericata* of putrefying substances seems to be due largely to the presence of indole, skatole, and ammonium carbonate. When dilute solutions of these compounds are placed in the fleece of live sheep, *L. sericata* females are attracted to oviposit. A technic for testing repellents based on this tropism has been devised.

IV. *On the chemistry of the fleece with reference to the susceptibility of sheep to blow-fly attack* (pp. 852-861).—This is a study of the distribution of the water-soluble matter in wool, referred to as suint and usually regarded as the dry residue from the evaporation of the product of the sudoriferous glands.

Convenient method of rearing the stable fly, A. E. DORR (*Jour. Econ. Ent.*, 30 (1937), No. 2, pp. 367-369).—A description is given of a method for rearing large numbers of the stablefly. It is pointed out that this fly has a very low resistance to sprays containing pyrethrum, rotenone, or thiocyanates and is not as suitable for laboratory repellency tests as is the housefly.

Weight of adult housefly and effect of a sublethal dose of sodium arsenite upon it, J. C. GAINES, S. CLARE, and C. H. RICHARDSON (*Jour. Econ. Ent.*, 30 (1937), No. 2, pp. 363-366, fig. 1).—In work conducted at the Iowa Experiment Station the mean weight of 402 male houseflies was found to be 18.075 mg and of 457 females 27.65 mg. "The distributions of these weights closely approached the normal. The weights of the females were more variable than those of the males, probably reflecting the somewhat unequal development of the eggs in the individuals of the female population. Flies which were allowed to feed ad libitum for 18 hr. upon sublethal concentrations of sodium arsenite in sucrose solution and then were fed milk for about 6 days did not differ significantly in weight from normally fed flies. The poisoned flies were distinctly more sluggish 6 days after feeding upon the arsenical solution than the control flies."

Testing fly sprays: Modified procedure in testing petroleum base insecticides by the settling mist method, A. E. ZERMUEHLEN and T. C. ALLEN (*Soap*, 12 (1936), No. 6, pp. 105-107, figs. 2).—An account is given in this contribution from the Wisconsin Experiment Station of a modified laboratory method developed which employs a screen wire testing cage for subjecting houseflies to a vaporized kerosene-base insecticide.

Acemyia calloti, a dipterous endoparasite of grasshoppers [trans. title], E. SÉGUY (*Ann. Parasitol. Humaine et Compar.*, 14 (1936), No. 4, pp. 321-326, figs. 2).—A dipterous parasite of *Acridium aegyptium* L. in Tunis is described as new under the name *A. calloti*.

A note on the attack of *Acridium aegyptium* by dipterous parasites of the genus *Acemyia* and on a fungus hyperparasite [trans. title], J. CALLOT (*Ann. Parasitol. Humaine et Compar.*, 14 (1936), No. 4, pp. 327-329).—The author records the parasitism of *A. aegyptium* by *Acemyia acuticornis* Meig. and *A. calloti* Séguy in the environs of Tunis. Notes on the life history of these parasites and a reference to the attack of *Acemyia* sp. by the fungus parasite *Beauveria globulifera* are included.

The Valencia orange and the Mediterranean fruit fly, *S. YEMIDYAH* (*Hadar*, 9 (1936), No. 8, pp. 167, 168, 170, 171, figs. 2).—Tests of Clensel bait of 5 percent strength, suspended in traps on trees during the seasons of 1934, 1935, and 1936, the details of which are given in tables, have shown that compared with other baits that draw various insects Clensel is especially suited to attract the Mediterranean fruitfly, the great majority of the trapped flies being females. It failed, however, to protect the Valencia crop during the three experimental seasons and also failed to protect deciduous fruits (apricots, peaches, plums, etc.) in the orchards of Miqueh-Israel.

Control of *Rhagoletis pomonella* (Walsh) in cultivated blueberry fields, C. S. BECKWITH and C. A. DOEHLERT (*Jour. Econ. Ent.*, 30 (1937), No. 2, pp. 294-297).—Contributing from the New Jersey Experiment Stations, the authors report studies which have shown that adults of the blueberry maggot can be killed in cultivated blueberry plantations by dusting from an airplane or auto-giro with from 10 to 15 lb. of derris dust (5 percent rotenone) to the acre. The time for the treatments in New Jersey is approximately June 27-30 and July 7-10.

Studies on *Oscinella frit* Linn.: Inheritance of resistance of oats to attack by the fly and the combination of resistance with other characters of agricultural importance, N. OUNLIFFE (*Ann. Appl. Biol.*, 23 (1936), No. 4, pp. 822-844, fig. 1).—The technic adopted in an attempt to hybridize oats by the use of a resistant variety as one parent is first described.

The experimental data reported have shown that resistance to attack by the frit fly is an inheritable character (or complex of characters), although difficult of precise measurement. Agricultural quality and resistance to attack are not incompatible. Wet weather conditions during the flight of the fly have a very marked effect in limiting the extent of damage to the crop. Varietal differences in extent of attack may be due to varietal differences in crude fiber production or deposition of silica, both tending to increase the larval difficulties and therefore the resistance of the plant.

Control of the potato flea-beetle (*Epitrix cucumeris* Harris), L. D. ANDERSON and H. G. WALKER (*Virginia Truck Sta. Bul.* 92 (1936), pp. 1359-1378, figs. 3).—The importance of the potato flea beetle as an enemy of potatoes in the northern part of Accomac County on the Eastern Shore of Virginia, where, by feeding upon the leaves, it has caused a serious reduction in yield, led to studies of its control on several farms near New Church.

Insecticide combinations with bordeaux and other sprays and dusts were tested on small plats with hand equipment, 37 in 1932, 29 in 1933, and 19 in 1934, and included the several arsenicals, fluorine, nicotine, pyrethrum, and derris products. The details of experimental work conducted in 1935 and 1936 on large plats with engine and traction power equipment are reported in tables.

A calcium arsenate-bordeaux mixture (2-4-6-50), applied at 7- to 10-day intervals throughout the growing season at the rate of 100 gal. per acre for each application, was found to give the best results and is recommended for flea beetle control. It is pointed out that particular precautions should be taken to time the applications so that the plants are kept thoroughly coated with this material while the new brood of beetles is appearing. In eastern Virginia, this is usually between June 15 and 25.

Although application of the calcium arsenate-bordeaux spray increases the yield nearly twice as much as dusting with a calcium arsenate-monohydrated copper sulfate-hydrated lime (25-20-55) mixture, this dust will give profitable returns, and its use is recommended when spraying is impracticable.

The contribution is accompanied by a list of 29 references to the literature.

On Chinese citrus flea-beetle and allied species, S. H. CHEN (*Sinensia*, 7 (1936), No. 3, pp. 371-398, figs. 30).—Of the 14 species of flea beetles here noted, 4 are said to be injurious to citrus in China, namely, *Olitea metallica* Chen, *Podagricomela weisei* Heikgt., *P. nigricollis* Chen, and *Throscoryssa citri* Maulik.

A note on the biology of *Chilocorus bipustulatus* and its status in Palestine, O. HECHT (*Hadar*, 9 (1936), No. 8, p. 171).—This is a brief preliminary note on a ladybeetle that occurs as a predator of the California red scale in the citrus groves of Palestine, observations of which were made with a view to determining why it has so little influence in checking the increase of this pest.

The ecology of *Passalus cornutus* Fabricius, a beetle which lives in rotting logs, A. S. PEARSE, M. T. PATTERSON, J. S. RANKIN, and G. W. WHARTON (*Ecol. Monog.*, 6 (1936), No. 4, pp. 455-490, figs. 43).—Following the brief introduction, this contribution on the horned passalus deals with its seasonal cycles, foods, and parasites and commensals, for which a new genus is erected and several species are described as new, the details being given in 8 tables. The account is accompanied by a list of 37 references to the literature.

Practical field methods of sampling soil for wireworms, E. W. JONES (*Jour. Agr. Res. [U. S.]*, 54 (1937), No. 2, pp. 123-134, figs. 7).—A report is made of a search for a time- and labor-saving system of random sampling that will give fairly accurate estimates of wireworm populations in the soil. The methods that have been selected consist in taking small sampling units of soil at random over the field. The field equipment consists of a metal sampling form, a soil-sifting machine or a soil-washing outfit, a tamper, a square-edged shovel, 10-qt. pails, and record blanks.

The data obtained with sampling units of three sizes—1, $\frac{1}{4}$, and $\frac{1}{8}$ sq. ft.—have been subjected to a statistical analysis. The wireworm distribution is moderately asymmetrical for the 1-square foot unit, the class frequency decreasing with markedly greater rapidity on one side of the maximum than on the other. The distributions show close agreement with the Poisson series. The 1-square-foot units give more precision in estimating the mean than either of the smaller units. In determining the smallest number of sampling units that may be taken, comparisons were made on the basis of four different population densities for each of the three units. Little practical reduction of the sampling error is obtained at any population by using more than 50 samples to determine the average number of wireworms per square foot of soil. At low population levels it is necessary to take at least 50 samples. At the intermediate and high levels of population a smaller number of samples is sufficient.

Nomenclature of *Listroderes obliquus* Klug (the vegetable weevil) (Coleoptera: Curculionidae), L. L. BUCHANAN (*Ent. Soc. Wash. Proc.*, 38 (1936), No. 3, pp. 204-208).—A chronology is given which lists references to the more important papers bearing on the nomenclature of *L. obliquus* and *L. costirostris* Schoen. *L. obliquus* appears to be the correct name.

Influence of size of brood cell upon size and variability of the honeybee, R. A. GROUT (*Jour. Econ. Ent.*, 30 (1937), No. 2, pp. 345-354, figs. 2).—Work at the Iowa Experiment Station is reported, the details being given in tables and graphs. The size of brood cell was found to affect the size of the adult worker bee, and significantly larger bees were obtained through the use of enlarged cell foundation. The size of brood cell was not sufficient to produce a much larger worker bee and apparently does not affect the variability of the adult worker bee. It was found that the length and the width of the right forewing tend to give the best estimation of the length of proboscis.

Disease resistance and American foulbrood.—Results of 2nd season of cooperative experiment, O. W. PARK, F. C. PELLET, and F. B. PADDOCK (*Amer. Bee Jour.*, 77 (1937), No. 1, pp. 20-25, 34, figs. 18).—The results of a second season of cooperative experiment by the Iowa Experiment Station (E. S. R., 75, p. 818) led to the conclusion that resistance to American foulbrood does exist in honeybees, and that the factor for resistance can be transmitted to offspring.

Disease resistance in honeybees, O. W. PARK (*Gleanings Bee Cult.*, 65 (1937), Nos. 2, pp. 82-84, 117, figs. 1; 3, pp. 148-150, 176, figs. 12; 4, pp. 232, 233, figs. 6).—A practical contribution from the Iowa Experiment Station, presented at the international conference at San Antonio, Tex., in November 1936, based upon work on the resistance to American foulbrood.

"The major findings for the two seasons may be summed up as follows: (1) Nearly half of the presumably resistant colonies tested have rid themselves of all symptoms of American foulbrood; (2) one-third of the second generation colonies tested have, likewise, eliminated all symptoms of this disease. It is concluded, therefore, that resistance to American foulbrood does exist in honeybees, that it is inheritable, and that the eventual development of a strain of honeybees highly resistant to this disease appears to be well within the realm of possibility."

Control of the pavement ant attacking eggplants, H. G. WALKER and L. D. ANDERSON (*Jour. Econ. Ent.*, 30 (1937), No. 2, pp. 312-314).—Report is made by the Virginia Truck Experiment Station of control work with the pavement ant, which has seriously injured many fields of eggplants in the Norfolk area during the last few years. In the spring of 1936 from 5 to more than 50 percent of the plants were found attacked. Many materials, including poison bran bait, a paris green-brown sugar bait, carbon disulfide emulsion, corrosive sublimate, derris, Creolol, Cyanogas, an ethylene dichloride-carbon tetrachloride mixture, 3 percent nicotine dust, and fish scrap, gave unsatisfactory results. Halowax, Loro, and naphthalene flakes gave promising results. Naphthalene flakes gave the most lasting protection but appeared to have a retarding effect upon the growth of the plants where it was applied in close contact with the roots.

On the oviposition habits of *Stilbula cynipiformis* Rossi (Hymen., Eucharidae), H. L. PARKER (*Ent. Soc. Wash. Proc.*, 39 (1937), No. 1, pp. 1-3, fig. 1).—Observations of *S. cynipiformis*, which, in the larval stage, is parasitic in the cocoons of the ant *Camponotus acethiops*, made near Montrieux (Var.), France, are reported.

Importation and laboratory breeding of two chalcid parasites of *Pseudococcus brevipes* (Okl.), W. CARTER (*Jour. Econ. Ent.*, 30 (1937), No. 2, pp. 370-372, fig. 1).—In work by the Hawaiian Pineapple Producers' Experiment Station a bisexual strain of the chalcid parasite *Hambletonia pseudococcina* Compere from Brazil failed to reproduce on the pineapple mealybug, but a parthenogenetic strain of *H. pseudococcina* from Colombia and Venezuela, as well as *Anagyrus coccidivorus* Dozier, reproduced on colonies of the pineapple mealybug in Hawaii. Satisfactory reproduction occurred on mealybug colonies established on young growing fruits enclosed in celluloid cages.

On the biology of certain species of *Holcoccneme* Kon. (Hymenoptera: Symphyta), H. W. MILES (*Ann. Appl. Biol.*, 23 (1936), No. 4, pp. 781-802, pls. 2, figs. 4).—The large larch sawfly *H. erichsoni* Htg., *H. caeruleocarpa* Htg. which feeds on willow and poplar, *H. lucida* Panz. which feeds on species of *Prunus*, and *H. crassa* Fall. which feeds on willow, poplar, and dock and is widely distributed in Great Britain are considered,

ANIMAL PRODUCTION

[Livestock investigations in Illinois] (*Illinois Sta. Rpt. 1935, pp. 73-93, 100-113, 115-120, 128-134, figs. 2*).—Beef cattle studies include the grazing value of bluegrass, orchard grass, and bromegrass pasture, lespedeza hay v. alfalfa hay for feeding steers, lespedeza straw in the winter ration of dry cows, dry lot compared with pasture for fattening beef calves, soybean oil meal v. cottonseed meal in the fattening ration, and tankage as a satisfactory protein supplement for steers, all by H. P. Rusk and R. R. Snapp; protein supplements required by hogs following fattening cattle, by Snapp; the effect of soybean hay and of pasture on the fat color in carcasses, and the effect of violent exercise just before slaughter on the color of beef, both by S. Bull; simplified methods for estimating the values of feeds and rations, the better utilization of balanced rations, and the failure of cystine amine to substitute for cystine in animal nutrition, all by H. H. Mitchell and T. S. Hamilton; and the relative contents of vitamins B and G in soybeans and corn, by Mitchell and J. R. Beadles.

In swine studies, results were reported on alfalfa pasture for growing and fattening swine and for brood sows, protein supplements for fattening 100-lb. pigs in dry lot, hulled oats in the swine ration and bonemeal as a supplement to hulled oats, and simplified rations for sows and pigs, all by W. E. Carroll and W. P. Garrigus; optimum protein levels for pigs of various weights, by Carroll and Mitchell; and the levels of iron and copper required for normal blood formation, by Mitchell and Hamilton.

Sheep tests yielded information on lespedeza as fall pasture for lambs, and supplemental corn silage v. soybean hay for sheep, both by W. G. Kammlade.

Tests by E. Roberts and J. H. Quisenberry demonstrated hereditary differences in corn which make certain kinds preferable to animals.

Poultry investigations reported include the value of various soybean meals for chick feeding, and the value of mineral feeding on interior egg quality, both by H. J. Sloan and L. E. Card; and the vitamin E requirement of chicks for normal development, and the protective action of yolk material against vitamin deficiency in chicks, by Sloan, Card, and F. B. Adamstone.

[Livestock investigations in Indiana] (*Indiana Sta. Rpt. 1936, pp. 22-24, 25-27, 56-59, 65, 66, figs. 5*).—Beef cattle studies reported include the comparative value of protein concentrates as supplements to rations for fattening calves, the value of limestone in rations for fattening calves, the comparative value of oat straw with limestone v. clover hay with and without limestone as dry roughages in beef cattle fattening rations otherwise containing shelled corn, cottonseed meal, and silage, and of leguminous roughage v. nonleguminous roughage with a protein concentrate for wintering cows with fall calves, the comparative cost of wintering cows with spring calves v. those with fall calves, and the relative cost of raising and fattening spring v. fall calves and native heifers v. steer calves.

Swine tests yielded information on the optimum calcium-phosphorus ratio in rations for swine; the effect of soybeans and soybean products on the quality of pork; ear corn compared with shelled corn for spring pigs; the relative values of roasted soybeans, soybean oil meal, and tankage as supplements in brood sow and pig rations; and the relation of shrinkage and fill to warm dressed yield in hogs.

Results of sheep studies are noted on grain for young lambs; suitable rations for poorly nursed lambs; the necessity of pasture in economic lamb production; the relative gains, finish, cost, and profit from shorn v. unshorn

native lambs; wintering breeding ewes; fattening western lambs; and the effect of calcium and phosphorus supplements in the ration on the formation of urinary calculi.

From poultry studies results are noted on marketing eggs under U. S. grades and on a graded basis, soybean oil meal in broiler rations, the use of large amounts of corn in laying rations, the influence of condensed buttermilk on egg yield, optimum protein levels in rations for young ducks, poultry housing, and the inheritance of growth tendencies in chickens.

Growth and metabolism studies with rats are noted on the cy-tine deficiency of raw and heated soybeans.

[*Livestock investigations in Tennessee*], M. JACOB (*Tennessee Sta. Rpt. 1936, pp. 19-24*).—Beef cattle studies reported include the comparative value of cottonseed meal, a mixture of cottonseed meal and tankage, peanut meal, and soybean meal in the wintering and finishing rations for 2-year-old steers, conducted at the main station; the amount of grain necessary for finishing 2-year-old steers on grass and the profitability of winter finishing baby beefs at the Middle Tennessee Substation; the amount of grain necessary for most economical finishing of baby beefs when they have free access to winter, spring, and summer pasture at the West Tennessee Substation; and the comparative value of shelled corn, ground shelled corn, and corn, cob, and husk meal when each is fed with cottonseed meal, alfalfa hay, and silage in the winter finishing of baby beefs at both the Middle and West Tennessee Substations.

Results are noted on the value of feeding grain to breeding ewes and to the lambs in the production of early spring lambs at the Middle Tennessee Substation.

[*Livestock investigations in Washington*] (*Washington Sta. Bul. 342 (1936), pp. 20-22, 23-25, 54-56*).—Information is presented on cereal and legume hays for fattening cattle, by R. McCall and H. Hackedorn; and the nutritive value of cereal hays and of first- and second-year sweetclover hay, and the value of field mixtures of Albit wheat and sweetclover as a hay and silage crop, all by J. Sotola and Hackedorn.

In poultry investigations results were noted on the chemical nature of watery white in eggs, by J. L. St. John; the protein requirements of chicks and of laying hens, all by J. S. Carver, V. Heiman, St. John, J. W. Cook, and H. W. Gerritz; the vitamin G requirement of poultry, the utilization of fish byproducts for poultry, and the vitamin G potency of dried milk products, all by Heiman and Carver; and the effect of hereditary and environmental factors on the interior quality of the egg, and the effects of storage conditions on egg quality, both by L. A. Wilhelm and Heiman.

Composition of some African foods and feeding-stuffs mainly of vegetable origin (*Imp. Bur. Anim. Nutr. [Aberdeen], Tech. Commun. 6 (1936), pp. 32*).—This is a tabulation of the composition (including organic constituents and in many cases ash analyses) of 566 items of food and feeding stuffs common to Africa. Sections on the composition of salt licks, edible earths, and native salts, and the geographical classification of foodstuffs, and an extensive bibliography are appended.

The composition and feeding value of heather at different periods of the year, B. THOMAS (*Jour. Min. Agr. [Gt. Brit.], 43 (1937), No. 11, pp. 1050-1055*).—Data are presented on the composition of heather at five different growth stages and from areas 3, 5, and 7 yr. after burning. It appears that young heather has the highest feeding value in early summer and that thereafter its value declines, reaching a minimum in early winter. This variation is most pro-

nounced on the area 3 yr. after burning, while at 7 yr. the seasonal variation is very slight. Heather is characterized by a medium protein content, a high ratio of true to crude protein, and a relatively constant crude fiber content at all seasons, with no evidence of an inverse relationship between crude protein and fiber.

Soft corn—how to store and feed it (*Illinois Sta. Circ. 293, Sup. (1935), pp. [6]*).—This mimeographed supplement (E. S. R., 52, p. 360) presents additional information on ways of utilizing soft corn for beef cattle feeding to the best advantage, by H. P. Rusk, and general suggestions for the storage of corn, by E. W. Lehman, G. H. Dungan, and P. E. Johnston.

The chemical composition of grass silage, S. J. WATSON and W. S. FERGUSON (*Jour. Agr. Sci. [England], 27 (1937), No. 1, pp. 1-42, figs. 3*).—This contribution from the Jealott's Hill Research Station, Berks, presents the results of analyses, including pH, crude protein, volatile base, amino acid, lactic acid, total volatile acid, acetic acid, and butyric acid, of 293 samples of silage. The majority of these were made from grassland herbage, while a limited number from ordinary silage crops, sugar beet tops, and potatoes were also included. Various lots of silage were prepared by the ordinary method, with additions of either molasses, whey, or moderate amounts of mineral acid with and without molasses, and by the A. I. V. process.

The additions of molasses, whey, or moderate amounts of mineral acid materially reduced the pH below that occurring in ordinary silage, and a still lower pH was attained in the A. I. V. lots. Volatile acid production, particularly butyric acid, increased as the pH of silage increased, but at pH ranges below 4.5 the quantity of butyric acid produced appears to be negligible for all practical purposes. The ordinary method proved unsatisfactory for high protein silage. Silages of similar pH were adjudged of equal quality regardless of the process employed.

The losses of dry matter and digestible nutrients in low-temperature silage, with and without added molasses or mineral acids, S. J. WATSON and W. S. FERGUSON (*Jour. Agr. Sci. [England], 27 (1937), No. 1, pp. 67-107*).—In this report of further silage studies the losses of dry matter and digestible nutrients incurred in the making of silage by different processes, based on the difference in analyses of the fresh material and the silage as removed, are presented in tabular form and discussed. It is concluded that while the A. I. V. process gives silage with the lowest losses, the advantage over the molasses process is not sufficient to justify its general application in preparing silage from grassland herbage. The ordinary process proved satisfactory when material in an advanced stage of maturity was ensiled.

Plant extracts in the nutrition of guinea pigs and rabbits, A. G. HOGAN and S. R. JOHNSON (*Soc. Expt. Biol. and Med. Proc., 35 (1936), No. 2, pp. 217-221*).—In this report from the Missouri Experiment Station it is shown that a deficient basal diet causing acute muscular dystrophy in guinea pigs and rabbits may be made entirely adequate by the addition of 10 percent of alfalfa meal to the diet. In attempts to substitute certain vegetable oils for alfalfa meal a corn oil gave a close approach to adequacy, and wheat germ oil proved very potent in this respect. A test ration of ground oats 60 percent, skim milk powder 33, wheat germ oil 4, and cod-liver oil, sodium chloride, and calcium carbonate, 1 percent each, invariably supported rapid growth in these animals but proved grossly inadequate during the reproductive stage. The juice from young barley plants offered ad libitum in place of drinking water rendered a deficient basal diet entirely adequate for guinea pigs. Further data are presented on the results of adding varying levels of concentrated plant juice, alcohol extract of dehydrated alfalfa, ether extract of dehydrated alfalfa,

alcohol extract of plant juice, and combinations of the latter two to such deficient diets. Varying degrees of protection were afforded by these supplements, but minimum protective doses were not established by this study.

The biological value of the proteins in hegari and the supplemental value of certain protein concentrates used in farm animal feeding, M. C. SMITH and G. H. ROEHM (*Jour. Agr. Res. [U. S.]*, 54 (1937), No. 2, pp. 135-146).—In an investigation at the Arizona Experiment Station both growth- and nitrogen-balance experiments were conducted with rats fed rations in which hegari served as the only source of nitrogen or was partly substituted with certain protein concentrates. The hegari proteins were inadequate for the support of growth and had a low biological value. Protein-rich feeds which showed definite supplemental relations with hegari proteins included skim milk powder, alfalfa leaf meal, soybean oil meal, meat scrap, gelatin, and tankage, while of the feeds tested only cottonseed meal and wheat gluten exerted no supplemental effect.

In a series of paired feeding experiments, lysine showed a marked ability to supplement hegari proteins, while tryptophane and cystine did not. Apparently lysine deficiency is a major cause for the low biological value of hegari, and proteins rich in this amino acid have a strong supplemental value.

Deficiencies known and suspected in live-stock nutrition of New Zealand, C. S. M. HOPKIRK (*New Zeal. Jour. Agr.*, 53 (1936), No. 4, pp. 200-204).—This is a brief résumé of livestock nutritional deficiency problems in New Zealand, with particular reference to iodine, phosphorus, calcium, magnesium, iron, and cobalt.

Studies on the mode of action of vitamin K, H. DAM, F. SCHÖNHEYDER, and E. TAGE-HANSEN (*Biochem. Jour.*, 30 (1936), No. 6, pp. 1075-1079).—In this phase of their vitamin K investigations the authors show that it is possible to precipitate prothrombin from the plasma of normal chicks (methods described), while the corresponding precipitate from the plasma of K-avitaminous chicks gave no evidence of prothrombin activity. The precipitate from the normal plasma remained active after extraction either with acetone and ether or alcohol and ether, while the lipid fraction removed by such extraction showed no prothrombin activity. A concentrate of vitamin K did not accelerate the clotting in vitro when tested against plasma and thrombokinase. The lipid fraction and the prothrombin fraction of a very yellow plasmata were found to contain 323 and 142 units of vitamin K per gram, respectively, but further study is needed to determine whether vitamin K is a constituent of more concentrated prothrombin preparations.

Effect of different methods of grazing on native vegetation and gains of steers in northern Great Plains, W. H. BLACK, A. L. BAKER, V. I. CLARK, and O. R. MATHEWS (*U. S. Dept. Agr., Tech. Bul.* 547 (1937), pp. 19, figs. 2).—This is a report of grazing investigations at the Dry Land Field Station, Ardmore, S. Dak., covering a period from 1919 through 1933, and planned to compare the effects of different methods of grazing native pastures on the vegetation and on the amount of gain of the grazing steers. The grazing areas consisted of an 80-acre pasture continuously overgrazed; a 150-acre pasture for continuous moderate grazing; and two 80-acre pastures for alternate intensive grazing, using one the first half of the season and the other the last half. The vegetation of the pastures included many species, with four grasses, namely, western wheatgrass, buffalo grass, blue grama, and plains bluegrass furnishing over 90 percent of the total feed. During the course of the investigation protected areas were clipped at 10, 20, 30, and 40 days and at the end of the season to represent various intensities of grazing.

The production of wheatgrass was seriously affected by frequent clipping and plains bluegrass to a less extent, while the yields of buffalo grass and blue grama were only slightly affected. No plants in the pastures appeared to benefit from close grazing or frequent clipping. The intensively and continuously grazed area (80 acres) carried an average of 12 animals annually during the first 6 yr., 10 animals during the second 6-yr. period, and 8 animals during the last 3 yr. Average per head and per acre annual gains for this area were 195 and 27.5, 129 and 16.1, and 162 and 16.2 lb. for the three periods, respectively. The moderately and continuously grazed area (150 acres) carried an average of 12 steers annually for the first 6 yr. and 10 head annually for the second 6 yr. This area was discontinued during the last 3-yr. period, 80 acres of it being used for grazing with steers receiving ground barley as a supplement. Average per head and per acre annual gains for this area were 248 and 18.9 and 191 and 12.7 lb. for the first and second periods, respectively, while steers receiving barley supplement (1931-33) averaged 270 pounds' gain per head and 27 pounds' gain per acre. The areas grazed intensively but alternately (160 acres) carried an average of 24 steers for the first 6-yr. period and 16 steers for the second 6-yr. and the last 3-yr. periods. Average per head and per acre gains were 200 and 29.3, 173 and 17.3, and 191 and 19.1 lb. for the three periods, respectively. Ordinarily the grazing season extended from May 21 until October. In most instances maximum gains were made in June, with gains becoming successively lower for each succeeding month on the continuously grazed areas and with heavy weight losses generally encountered in October. In the brief trial with barley as a supplement to pasture the rate of gain of steers was materially increased, but in only one year out of three was the increased sale value of steers sufficiently great to offset the additional cost of the barley.

Maintaining a commercial beef cow herd, G. A. BRANAMAN (*Michigan Sta. Quart. Bul.*, 19 (1937), No. 3, pp. 155, 156).—The feed required to maintain a commercial beef herd is indicated, with particular reference to the feed budget for wintering the cows and the ability of cows to utilize large amounts of low quality roughage.

Red, white, and roan, A. H. SANDERS (*Chicago: Amer. Shorthorn Breeders' Assoc.*, 1936, pp. IX+630, [figs. 60]).—This book discusses the origin of the Shorthorn breed of cattle in Great Britain and its early introduction into America, and deals particularly with the more important phases of the progress of this breed in the United States during the past three decades.

Sheep farming, A. FRASER (*London: Crosby Lockwood & Son*, 1937, pp. 178, figs. 24).—This book gives an insight into the present status of the sheep industry in the British Isles and deals with the practical aspects of the care and management of the farm flock. "It is written from the point of view of the field rather than the laboratory. . . . It will be read with interest not only by sheep farmers and shepherds, but by all who are interested in the country."

Feeding and management experiments with brood sows and litters, C. M. VESTAL (*Indiana Sta. Bul.* 413 (1936), pp. 44, fig. 1).—This bulletin presents the details of 19 experiments with sows and their litters.

Corn alone gave good results as a gestation ration for mature sows when they were so fed and exercised as to maintain a medium condition but was unsatisfactory when such sows were allowed to become fat. It was not suitable as a gestation ration for gilts regardless of condition or amount of exercise. Corn and oats proved a satisfactory gestation ration for either sows or gilts when medium condition was maintained. Condition during gestation was a more important factor than exercise on the ability of sows to raise pigs. When tankage was added to the corn and oats ration, differences in con-

dition and exercise during gestation did not materially affect the pig-producing efficiency of sows and gilts.

Soybeans without minerals were not satisfactory as a supplement in either the gestation or suckling rations. Soybeans with minerals were as satisfactory as tankage in supplementing corn but were not satisfactory as a substitute for tankage and oats in the gestation ration, and their use in suckling rations as a substitute for tankage gave inconclusive results.

Mineral mixtures fed as supplements to brood sow rations were of questionable influence, but apparently best results were obtained when the grain and minerals were fed separately. Dried kelp fed alone or in mineral mixtures did not improve the rations.

Sows maintained in medium condition required approximately $1\frac{1}{2}$ lb. and fat sows about 2 lb. of feed daily per 100 lb. of live weight. The average weights of mature sows and of gilts at weaning time were approximately 20 lb. and 40 lb., respectively, greater than their average weights at breeding time.

In addition to the above experiments a summary of data from the experimental swine herd from 1921 to 1935 indicated that 2-year-old sows were more productive than gilts or older sows. The rate of gain of suckling pigs increased with increase in birth weight. As the size of litters increased the average birth weight of pigs decreased. The order in which pigs were farrowed in the litter was not definitely related to their birth weight, and less than 50 percent of pigs weighing 2 lb. or less at birth survived to normal weaning age.

The use of concentrates with factory buttermilk in fattening bacon pigs, C. P. McMEERAN (*New Zeal. Jour. Agr.*, 53 (1936), No. 6, pp. 340-353).—This contribution from the Massey Agricultural College reports results of three series of feeding trials with fattening bacon pigs. In the first of these buttermilk as the sole diet was compared with buttermilk supplemented with either meat meal, a mixture of meat meal and wheat pollards, or a cereal meal; in the second series buttermilk alone was compared with buttermilk supplemented with cereal meal at various levels; and in the third series buttermilk alone was compared with buttermilk supplemented with cereal meal over varying weight ranges.

The data indicate that from 700 to 800 gal. of buttermilk will produce 100 lb. of dressed meat in pigs fattened from weaning stage to bacon weight. The economy of adding concentrate supplements depends on the relative values of the bacon and such feeds. In general, concentrate feeding should be limited to from 1 to 1.5 lb. per 100 lb. of live weight daily. The concentrate should be fed particularly during the early stages of growth, while "topping off" pigs on meal should be avoided when milk supplies are adequate.

Pig testing: An analysis of the results of bacon pig testing, S. BERGE (*Meld. Norges Landbr. Høiskole*, 16 (1936), No. 8-9, pp. 641-840, figs. 54; *Eng. abs.*, pp. 833-837).—This extensive report is based on studies with the Landrace and Large White breeds of bacon pigs and crossbreds from these breeds. Successive sections of the report deal with the manner in which the feed consumption of a litter varies in relation to the time used in increasing from 20 to 90 kg live weight; the growth rate of pigs in the first 8 weeks after farrowing, with information on average birth weights and average length of gestation periods; the growth of bacon pigs particularly during the period from 20 to 90 kg, with an analysis of variation in growth of individuals at different growth stages, and the correlation between growth rates at different periods of development; the growth of breeding animals from birth to 3 yr. of age; and an analysis of the variance of certain characters examined.

The oxygen uptake of pork and bacon: A factor in the production and preservation of the colour of bacon, J. BROOKS (*Jour. Soc. Chem. Indus., Trans.*, 55 (1936), No. 3, pp. 12T-14T).—The author has measured the oxygen uptake of pork and bacon, employing samples of varying thickness subjected to a wide range of temperature. The respiratory quotient of bacon has also been determined.

At 0° C. the relative rates of diffusion and uptake of oxygen are such as to reduce the oxygen concentration of the sample to zero except in the thin surface layer, and the depth of the oxygen layer decreases with rising temperature. Hence, in considering the factors affecting the formation of nitric oxide hemoglobin in such tissue, the complex effect of oxygen may be ignored. This absence of oxygen in the bulk of the tissue tends to insure stability of color, since nitric oxide hemoglobin seems to be stable indefinitely in the absence of oxygen, whereas in the presence of oxygen it is slowly converted to methemoglobin.

Poultry feeds and feeding, G. ROBERTSON and H. S. GUTTERIDGE (*Canada Dept. Agr. Pub.* 541 (1936), pp. 38, figs. 11).—This bulletin presents information on the physical and chemical nature of a wide range of feeding stuffs suitable for poultry feeding, along with practical suggestions on the compounding of rations and methods of feeding different types of fowl.

The evolution of a sanitary type of chick feeder, L. VAN ES and J. F. OLNEY (*Nebraska Sta. Bul.* 306 (1937), pp. 14, figs. 13).—This bulletin describes a series of chick feeders constructed and tried out in the course of evolving a feeder which would entirely prevent fecal contamination of the feed. Working plans are presented for the construction of a feeder which proved fairly adequate in this respect.

Digestibility trials with poultry, VII, VIII, E. T. HALNAN (*Jour. Agr. Sci. [England]*, 27 (1937), No. 1, pp. 126-142).—This is a continuation of a series of studies previously noted (*E. S. R.*, 63, p. 166).

VII. The digestibility of wheat offals, with a note on the apparent discrepancy between the digestibility coefficients and nutritive values of these products.—Trials were conducted to compare the digestibility of broad bran, straight-run middlings, and fine middlings, each product being fed as the sole diet to four Light Sussex cockerels in the respective trials, each of which extended over a 16-day collection period. The digestibility of crude fiber was very low in all products, while digestibility of other constituents was relatively low in the bran, much higher in straight-run middlings, and highest in fine middlings, with the exception of crude protein digestibility which averaged highest in the straight-run middlings. In addition brief feeding trials with growing chicks are reported, giving evidence that the inclusion of bran in the chick ration is justified on dietetic grounds in spite of its relatively poor value as measured by digestion trials.

VIII. The digestibility of dried molasses sugar-beet pulp.—Employing the same experimental procedure as above, the digestibility of a mixture of 10 parts of dried molasses beet pulp and 40 parts of fine wheat middlings was determined. Using the digestibility values for fine middlings as determined in the previous trial, the apparent digestibility of the dried beet pulp was extremely low, averaging 17.5 percent for organic matter, 33.5 for crude protein, 22.1 percent for nitrogen-free extract, and 0 for crude fat and crude fiber. These findings are discussed with reference to the possible depression of the digestibility of middlings in the mixture, and are briefly compared with the findings of other investigators.

Further studies on the growth factor required by chicks: The essential nature of arginine, A. ARNOLD, O. L. KLINE, C. A. ELVEHJEM, and E. B. HART (*Jour. Biol. Chem.*, 116 (1936), No. 2, pp. 699-709, fig. 1).—Continuing this line of investigation (*E. S. R.*, 73, p. 370), the authors have confirmed previous findings on the growth-promoting activity of water-extracted liver residue when used as a supplement to a yellow corn-wheat middlings-casein diet for chicks. Of other supplements tested in this respect pork heart and soybean meal were almost as potent as the liver residue, wheat germ, pork kidney, spleen, muscle, and brain were less active than the liver residue, and added quantities of yeast or casein in the diet gave no response in added growth.

Edestin, peanut meal, and liver residue each were found to have a growth-promoting action proportional to their arginine content when used as a supplement to the above basal diet. Direct supplements of arginine in the form of the carbonate or hydrochloride at the rate of 1 percent to the yellow corn-middlings-casein diet or a dextrin-casein-peanut oil diet gave rapid growth response. The results indicate that arginine is an essential amino acid for chicks which apparently is not supplied at an optimum level in ordinary grain rations during the rapid growth period.

Preliminary observations on the relationship between production, fertility, and hatchability of eggs, M. R. MONTEMAYOR (*Philippine Jour. Anim. Indus.*, 3 (1936), No. 6, pp. 467-476, figs. 3).—Information is presented on the seasonal variation in production, fertility, and hatchability of eggs of the Single Comb White Leghorn, Rhode Island Red, and Cantonese breeds under Philippine conditions. The results failed to establish any definite relations between fertility and hatchability or between production and fertility of the eggs.

Effect of temperature, humidity, and other factors on hatch of hens' eggs and on energy metabolism of chick embryos, H. G. BAROTT (*U. S. Dept. Agr., Tech. Bul.* 553 (1937), pp. 46, figs. 18).—These experiments were designed to determine the effect of varying the temperature, humidity, oxygen concentration, or carbon dioxide concentration in the incubator on the percentage of hatch and the energy metabolism of the developing chick embryo. Selected fresh White Leghorn eggs were incubated in specially designed, constant-temperature, continuous-water-flow calorimeters which also functioned as closed-type respiration chambers.

In determining the effect of temperature variations the following were used: 96°, 98°, 99°, 100°, 102°, and 103.5° F., while a relative humidity of 60 percent, a carbon dioxide concentration below 0.5 percent, and an oxygen concentration of 21 percent were maintained constantly. Maximum hatch was obtained at 100°. The higher the temperature the greater was the energy metabolism and rate of gaseous exchange of the embryos and the earlier the hatch. The length of the incubation period was 19½ days at 103.5°, 20¼ days at 100°, and 23½ days at 96°.

Relative humidities ranging from 8 to 88 percent were employed with a temperature of 102°, carbon dioxide below 0.5 percent, and oxygen at 21 percent constantly maintained. The optimum humidity for hatch under these conditions was 58 percent. In a second series, in which a constant temperature of 100° was employed, optimum humidity was found to be 61 percent. In both series as humidity varied either way from the optimum the hatch became less and the energy metabolism of the embryos became lower. The greater the deviation from the optimum the greater was the detrimental effect. Water elimination of the embryo was primarily dependent on the humidity of the atmosphere and declined in direct proportion to increase in humidity (*E. S. R.*, 77, p. 235).

Variations in carbon dioxide concentration with oxygen held constant at 21 percent had very pronounced effects. With 4-percent carbon dioxide less than one-fourth as many chicks were hatched as with 0.5 percent, and only a 16-percent hatch was obtained when the carbon dioxide was allowed to accumulate to 10 percent and maintained constant at that level for the remainder of the incubation period. Metabolism was greatest at the lowest concentration and decreased with increase of carbon dioxide. When the oxygen percentage was variously held at 15, 18, 21, 30, 40, and 50 percent the best hatches were obtained at the 21-percent level. Hatchability declined as the concentration varied either way, but a decrease was much more harmful than an increase. Gaseous exchange and heat elimination were practically the same at 21, 30, and 40 percent but were retarded at 18- or 50-percent levels, and at 15 percent the effect was very detrimental. Information is given on the respiratory quotient and thermal quotient at various stages of incubation. They indicate a carbohydrate metabolism during the first few days of incubation and almost exclusively a fat and protein metabolism after about the tenth day.

It is concluded that, under the conditions indicated, incubation temperature should not vary more than 0.5° from the 100° optimum, that relative humidity may vary 10 percent from the 61 percent optimum with little detrimental effect, that carbon dioxide concentration should not exceed 1 percent, and that oxygen concentration should not fall below 21 percent.

A new species of micro-organism (*Proteus melanovogenes*) causing black rot in eggs, A. A. MILES and E. T. HALNAN (*Jour. Hyg. [London]*, 37 (1937), No. 1, pp. 79-97, fig. 1).—In an investigation of the cause of a black rot occasionally observed in imported eggs, the specific causative organism was isolated and has been described. This organism proved markedly putrefactive, and the name *P. melanovogenes* has been provisionally assigned to it. It produced rot experimentally either when inoculated into fresh eggs or when brushed on the shell of such eggs. In a small number of trials hens inoculated with the organism laid eggs which failed to develop the specific rot. The organism has been found in a number of places, including English soils and manures, but its source, general distribution, and the conditions necessary for infection were not determined.

Turkey production: Suggestions for West Virginia, T. B. CLARK and H. M. HYRE (*West Virginia Sta. Circ.* 73 (1937), pp. 16, figs. 7).—Included in this practical circular are suggestions on selection, feeding, and management of the breeding flock, incubation, brooding the poults, management of growing turkeys, marketing, killing and dressing, and sanitation practices.

A statistical study of squab production in the White King breed, C. S. PLATT (*Jour. Agr. Res. [U. S.]*, 54 (1937), No. 3, pp. 235-237, fig. 1).—The New Jersey Experiment Stations have studied the relation between total weight of squabs produced annually and certain observed factors in 133 pairs of White King pigeons. The mean annual weight of squabs per pair of pigeons that survived a year was 225.9 ± 3.57 oz. Coefficients of correlation between total weight of squabs and other factors observed were total number of squabs 0.9512 ± 0.0055 , percentage fertility of eggs 0.5874 ± 0.0476 , percentage livability of squabs 0.5002 ± 0.0431 , egg production per pair 0.2877 ± 0.0526 , percentage hatchability of fertile eggs 0.1470 ± 0.0562 , and average squab weight 0.0010 ± 0.0568 .

DAIRY FARMING—DAIRYING

[Investigations with dairy cattle and dairy products] (*Illinois Sta. Rpt.* 1935, pp. 140-153, figs. 5).—In dairy cattle studies, results are briefly noted on methods for evaluating dairy sires, by W. W. Yapp; the relative effects of age

and size of cows on milk yield, by W. L. Gaines; lespedeza hay v. alfalfa hay for milking cows, by W. B. Nevens; pasture improvement studies by Nevens, Yapp, and A. F. Kuhlman; and the relative composition of the milk of five dairy breeds, by O. R. Overman and O. F. Garrett.

Studies with dairy products gave results on the character of yellow color in milk, by Yapp and Kuhlman; the use of acidophilus milk in ice cream manufacture, and methods of producing high quality cream, both by M. J. Prucha; simple methods in dairy sterilization, by Prucha and J. M. Brannon; and the relation of coli and aerogenes groups of bacteria to milk sanitation, by Brannon.

[Investigations with dairy cattle and dairy products in Indiana] (*Indiana Sta. Rpt. 1936, pp. 29-34, 59, 60, 65*).—Included in this report are the results of studies on the value of legume hay and cracked corn as a winter ration for yearling heifers; the effect of soybeans in the ration on the fat test of milk and on the vitamin A value of butter; the rate of change in the vitamin A content of milk when rations are varied; the vitamin A requirements of cows for the production of butterfat of a maximum vitamin A value; the determination of carotene in butter; the relationship of carotene content to the vitamin A value of butterfat; the enzymes in sweet and sour farm-skimmed cream as related to keeping qualities of butter; the effectiveness of lye and chlorine solutions for sterilizing milking machines; certain factors related to the development of cappy flavor in milk; the influence of H-ion concentration and season of the year on the keeping quality of commercially manufactured butter; the frequency of occurrence of yeasts and molds and *Escherichia-Aerobacter* organisms in Indiana butter; the lecithin content of milk and its products; physical, chemical, and bacteriological factors affecting the body, texture, and quality of ice cream; the influence of a milk plant quality program on quality improvement of the milk and on the price paid to producers; and difficulties encountered in the application of the cream sediment test.

[Abstracts of dissertations] (*Iowa State Col. Jour. Sci., 11 (1936), No. 1, pp. 54-56, 78-80, 105, 106, 113, 114*).—Abstracts of the following doctoral theses from the Iowa State College are included: The Influence of Various Procedures on the Flavor and Keeping Quality of Butter, by N. E. Fabricius; A Study of Some Lipolytic Microorganisms Isolated from Dairy Products, by H. F. Long; Gastric Digestion of Soybean Flour When Used as a Substitute for Cows' Milk in Feeding Dairy Calves, by L. N. Shoptaw; and Bacteriological Studies on Some Defects of Cream Cheese Spreads, by J. B. Stine.

[Dairy cattle feeding and grazing experiments in Tennessee] (*Tennessee Sta. Rpt. 1936, pp. 24, 63, 64, figs. 2*).—Tests were reported from the West Tennessee Substation on the amount of grain necessary for most economical milk production when cows have access to all-year pasture, by B. P. Hazlewood; and from the Middle Tennessee Substation comparing the production of cows on a full-grain with those on a half-grain ration, by M. Jacob.

[Investigations with dairy cattle and dairy products in Washington], R. E. HODGSON, J. C. KNOTT, E. V. ELLINGTON, H. K. MURER, R. R. GRAVES, E. L. OVERHOLSER, C. C. PROUTY, and H. A. BENDIXEN (*Washington Sta. Bul. 342 (1936), pp. 25-31*).—Dairy cattle studies, in cooperation with the U. S. D. A. Bureau of Dairy Industry, yielded information on the feeding value of artificially dried forage crops and of green stacked forage crops, the nutritive value of home-grown hay and silage rations for dairy cattle and of pea cannery refuse, the composition and apparent digestibility of the flat pea, the determination of apparent digestibility by modified procedures, and the utilization of cull apples as a feed for dairy cattle.

Studies with dairy products gave results on the effect of pasteurization upon the bacterial content of high quality milk, the growth of micro-organisms in milk from infected udder quarters, and the value of the H-ion determination of the butter serum in the scoring of butter.

Dry vs. succulent roughage in the dairy ration. O. M. CAMBURN, H. B. ELLENBERGER, J. A. NEWLANDER, and C. H. JONES (*Vermont Sta. Bul.* 412 (1937), pp. 12).—This bulletin presents the results secured in four feeding trials with milking cows in which rations containing only dry roughage were compared with those containing both dry and succulent roughages. In two trials, including one double reversal and one continuous trial, timothy hay replaced fresh corn silage in the ration on a dry matter basis and in the other two, including both a reversal and a continuous trial, artificially dehydrated silage replaced normal corn silage in the ration. All cows had constant access to drinking water.

No significant advantage could be ascribed to either type of ration, the average daily yield of 4-percent milk, the total water intake, the water intake per pound of 4-percent milk, and the total digestible nutrient requirement per pound of 4-percent milk being very similar on the two types of rations. It appears that dairy cows having free access to drinking water secure enough water whether fed a succulent or nonsucculent ration, that there is little to be gained by furnishing any water in the form of succulent roughage, and that the value of a feed is measured primarily by its digestible nutrient content and not by its water content.

Some factors affecting breeding efficiency in dairy cattle. G. E. TAYLOR (*Michigan Sta. Quart. Bul.*, 19 (1937), No. 3, pp. 156-159).—An analysis of the breeding records of a tuberculosis- and Bang's disease-free dairy herd, including the Jersey, Guernsey, Brown Swiss, Ayrshire, and Holstein breeds, indicated that there is no advantage in breeding heifers at an earlier age than from 17 to 18 mo. in an effort to improve their breeding efficiency, that heifers require more services per conception than older animals, and that the practice of breeding cows so that they will freshen once in every 12 mo. is to be recommended since further delay generally caused an increase in the number of services required per conception.

Changes in weight of new born dairy calves as related to the method of feeding. C. L. COLE (*Jour. Dairy Sci.*, 20 (1937), No. 2, pp. 113-116).—The Minnesota Experiment Station has recorded daily weights of three groups of calves from birth to 14 days of age. Calves in one lot were removed from their dams immediately after birth without nursing, those in the second lot were left with their dams for 48 hr., and in the third lot for 96 hr. after birth. The calves allowed to nurse for 2 days or longer did not suffer a loss in weight immediately following birth but rather showed immediate gains, while calves removed from their dams without nursing showed a loss in weight during the first 48 hr. Calves not allowed to nurse were much easier to teach to drink milk and seemed to get a better start during the first 14 days than those calves allowed to nurse for a short period. Calves in lots 1, 2, and 3 weighed 65.7, 65, and 65.6 lb., respectively, at birth and 80.4, 71.8, and 69.8 lb., respectively, at 14 days of age.

The heat denaturation of albumin and globulin in milk.—II, Denaturation and degradation of protein at temperatures of 75-120° C, S. J. ROWLAND (*Jour. Dairy Res.* [London], 8 (1937), No. 1, pp. 1-5).—Continuing this study (E. S. R., 71, p. 91), milk was heated for various periods within a higher temperature range than was previously employed. Denaturation of albumin

and globulin took place rapidly and was complete in approximately 60, 30, 10 to 15, and 5 to 10 min. at 80°, 90°, 95°, and 100°, respectively. Heating milk at temperatures up to 103° did not change the nonprotein content, but when heated at 115° and 120° the denaturation of the albumin and globulin was followed by an appreciable hydrolysis, resulting in considerable increases in the proteose and nonprotein nitrogen contents.

The soluble protein fraction of milk, S. J. ROWLAND (*Jour. Dairy Res.* [London] 8 (1937), No. 1, pp. 6-14, figs. 2).—In a series of normal milk samples the maximum amount of albumin and globulin rendered coagulable by heating the milk represented an average of 76 percent of the total soluble protein nitrogen present. Reasons are advanced for the conclusion that the soluble protein fraction of normal fresh milk is composed of about 76 percent of true albumin and globulin and 24 percent of secondary proteins of a proteose-peptone nature.

Oxidized flavor in milk, II-IV (*Jour. Dairy Sci.*, 19 (1936), Nos. 11, pp. 671-682; 12, pp. 753-760, figs. 2; 20 (1937), No. 3, pp. 133-145).—These articles are in continuation of a series (E. S. R., 73, p. 837).

II. *The effects of homogenization, agitation, and freezing of milk on its subsequent susceptibility to oxidized flavor development*, L. M. Thurston, W. C. Brown, and R. B. Dustman.—It is demonstrated that homogenization, prolonged agitation at low temperature, and freezing and thawing of milk greatly reduce or completely eliminate its susceptibility to the development of oxidized flavor, even when containing minimal amounts of copper. Although the three treatments differ in their effect on the physical constitution of milk, there is a great similarity in the effect of each as regards oxidized flavor. It is suggested that each process probably causes some realignment of the materials, particularly lecithin, which are adsorbed on the fat globule. Additional evidence has been secured that lecithin is the constituent of milk affected when oxidized flavors develop, although the manner in which either lecithin or butterfat is protected from oxidization by the above treatments has not been demonstrated.

III. *The time of copper contamination during production and processing, and aeration versus no aeration as related to oxidized flavor development*, W. C. Brown, L. M. Thurston, and R. B. Dustman.—All milk used in this phase of the study was from cows known to produce milk readily susceptible to oxidation. The milk was drawn and transported in aluminum utensils, and all pasteurization and cooling were carried out in glass equipment. In the pasteurization studies milk was pasteurized at 143° F. for 30 min., and copper was added to the various samples in amounts ranging from 0.5 to 2.5 p. p. m.

Contamination of the milk with copper after pasteurization resulted in a more frequent and more intense development of oxidized flavor than did contamination with identical amounts of copper before pasteurization, while additions of copper to unpasteurized milk gave results quite similar to those obtained by contamination after pasteurization.

In the cooling studies no significant differences were detected in the intensity of oxidized flavor in milk samples containing like amounts of copper cooled over a surface cooler or by use of an internal cooler.

IV. *Studies of the relation of the feed of the cow to oxidized flavor*, W. C. Brown, L. M. Thurston, and R. B. Dustman.—Studies on samples of mixed herd milk collected once a week throughout 1 yr. and carefully handled to prevent unintentional iron or copper contamination indicated that (1) mixed herd milk never developed oxidized flavor when no iron or copper was added to it, (2) much more iron than copper was required to produce oxidized flavor, and (3) the changing of the cows from dry feeding to a dry feeding and pasture regime caused the milk to become nonsusceptible to oxidized flavor develop-

ment. Considerable variation was noted among individual cows with respect to the tendency for oxidized flavor to develop in their milk. The addition of 1 qt. of either tomato or lemon juice or of $\frac{1}{2}$ g of pure crystalline ascorbic acid per animal daily to the rations of cows in dry feeding greatly reduced the susceptibility of the milk to oxidized flavor development.

The production of milk of abnormal composition by animals free from udder streptococci, E. G. HASTINGS and B. A. BEACH (*Jour. Agr. Res. [U. S.]*, 54 (1937), No. 3, pp. 199-220).—In this study by the Wisconsin Experiment Station, the production of milk of abnormal composition in a herd of 31 Holstein cows which had had no contact with other cattle either during or for 1 yr. prior to the period of observation was studied during their first lactation period. Periodic samples of foremilk from the separate quarters of each animal were analyzed for chlorine, for catalase, and for pH value, and were cultured on glucose agar and in milk. Additional samples of foremilk and of the entire product of each quarter from animals producing abnormal milk were further examined as to composition and bacterial content.

On the basis of commonly accepted standards for normal milk, namely, a pH value below 6.5, a chlorine value below 0.15 percent, and a catalase value of under 50 percent, one or more samples of milk which would be classed as abnormal were obtained from 23 of the 31 cows, and on final analysis of the records 14 of the cows were considered definitely abnormal while 17 were considered normal. The abnormalities noted were such as to indicate a chronic inflammation of low intensity in the quarters involved. No streptococci were found in any sample, thus eliminating *Streptococcus agalactiae* as the cause. No significant differences were demonstrated in the types of bacteria found in the quarters producing normal and abnormal milks, suggesting that the disturbance may be due to an increased development of common udder flora over that in normal udders. The results did not indicate that this condition passed from one animal to another in the herd.

A comparison of ten presumptive test media used in the detection of the *Escherichia-Aerobacter* group in milk, M. A. FARRELL (*Jour. Dairy Sci.*, 20 (1937), No. 2, pp. 67-75).—In this study at the Pennsylvania Experiment Station, 66 samples of raw and certified milk were planted into each of the 10 presumptive test media compared, namely, lactose broth, buffered lactose broth, brilliant green lactose bile broth 2 percent, fuchsin lactose broth, methylene blue bromocresol purple broth, crystal violet lactose broth, formate ricinoleate broth, gentian violet lactose broth, MacConkey's peptone lactose bile broth, and trypan-flavine broth. Samples were incubated and the results recorded according to standard methods.

The brilliant green lactose bile broth, fuchsin lactose broth, and methylene blue bromocresol purple broth were found to be equally efficient in the detection of the *Escherichia-Aerobacter* group, while the remaining 7 media proved definitely less efficient in this respect. These data have been employed to determine the accuracy of the "most probable number" index as a measure of density of this group of organisms in milk. The method was found to be very inaccurate with certain of the media tested. The opinion is expressed that there is need for the development of a more efficient presumptive test medium for the detection of the *Escherichia-Aerobacter* group of organisms in milk.

Variants of *Streptococcus lactis* which do not ferment lactose, E. S. YAWGER, JR., and J. M. SHERMAN (*Jour. Dairy Sci.*, 20 (1937), No. 2, pp. 83-86).—The [New York] Cornell Experiment Station reports the isolation from milk of four cultures of *S. lactis* which failed to curdle milk. When subjected to numerous cultural tests these cultures were shown to agree with typical *S. lactis* strains in all respects except their lack of ability to ferment lactose.

It is recommended that these organisms be recognized as naturally occurring variants of *S. lactis*. In support of this view, one of these strains, after 10 months' cultivation, has acquired the ability to ferment lactose feebly.

Fermentative variability among substrains of *Streptococcus cremoris* and *Streptococcus lactis* obtained from pure cultures, J. M. SHERMAN and R. V. HUSSONG (*Jour. Dairy Sci.*, 20 (1937), No. 2, pp. 101-103).—In this study at the [New York] Cornell Experiment Station, a parent culture of *S. cremoris* which would not ferment either maltose or sucrose and a parent culture of *S. lactis* which would ferment maltose but not sucrose were employed. Of 453 substrains developed from the former only 217 were typical of the parent stock, while 229 were maltose+ sucrose-, 11 were maltose- sucrose+, and 1 was maltose+ sucrose+. Of 757 strains of *S. lactis* developed, 756 were typical of the parent and only 1 was maltose+ sucrose+. These data are interpreted to indicate that it is doubtful if a differentiation between these two species can be founded on fermentation tests.

Further studies on home pasteurization of milk, E. D. DEVEREUX, C. S. BRYAN, and D. H. LAURENT (*Michigan Sta. Quart. Bul.*, 19 (1937), No. 3, pp. 172-175).—Continuing these studies (E. S. R., 76, p. 242), milk samples containing mastitis streptococci and contagious abortion bacteria were heated to various temperatures and for various time intervals in an ordinary double boiler, in bottles submerged in an open water bath, and in bottles in a pressure cooker. It is concluded that both types of organisms in the milk were completely destroyed with a reasonable margin of safety when heat was so applied that the water in the double boiler or in the water bath containing the bottled milk would boil in approximately 18 min. These organisms in bottled milk in a pressure cooker were destroyed when all air was expelled from the cooker and a steam pressure of 5 lb. was maintained for 5 min. In addition, any of the above heat treatments reduced the total bacterial content of the milk over 99 percent. Immediate cooling after pasteurization, storing in a cold place, and prevention of recontamination insured a low count milk.

Twenty-second annual report of the creamery license division, T. H. BINNEY (*Indiana Sta. Circ.* 224 (1936), pp. 16).—This circular indicates the number of creamery licenses issued and the number of testers' licenses granted during the year ended March 31, 1936, and lists the licensed dairy manufacturing plants in Indiana.

Body of cultured cream, E. S. GUTHRIE ([New York] Cornell Sta. Bul. 666 (1937), pp. 12, figs. 8).—This bulletin presents information on the effect of certain plant practices and the addition of various substances on the smoothness, dryness, and viscosity of cultured cream. Pasteurization temperatures at about 165° F. with a 30-min. holding period and homogenization at approximately 3,000 lb. per square inch gave the smoothest, driest, and most viscous body, while homogenization temperatures of from 145° to 165° were most desirable, depending on the thickness of body desired. Rehomogenizing at pasteurizing temperatures or slightly below increased the firmness, dryness, and viscosity of the body. The addition of skim milk powder to raise the solids-not-fat content distinctly increased the viscosity without affecting the texture of the body. The use of rennet resulted in a firmer and more viscous body, while the use of gelatin noticeably increased viscosity but produced a lumpy texture and a body that lost moisture. A ropy starter had little effect on the viscosity of the cultured cream. Increasing the fat content from 18 to 24 percent resulted in decreased viscosity, but maintaining a constant solids-not-fat to fat ratio as the fat content was increased from 18 to 24 percent gave a body of uniform viscosity.

Some factors affecting the properties of whipping cream and the quality of the finished product, W. S. MUELLER, M. J. MACK, and H. G. LINDQUIST (*Massachusetts Sta. Bul. 335 (1936), pp. 23, figs. 19*).—This bulletin presents information on the whipping ability of cream and on the viscosity, overrun, and serum drainage of the finished product as influenced by various factors.

Whipping temperatures above 40° F. for 36-percent cream reduced maximum stiffness and percentage overrun and increased the serum drainage of the whipped cream. A separation temperature of 90° produced a more satisfactory whipping cream than temperatures above 100°. Standardizing either before or after pasteurization, using either skim milk or whole milk for standardizing and varying pasteurization temperatures from 145° to 165°, did not noticeably affect whipping qualities. Cream containing 30 percent butterfat whipped satisfactorily. No practical advantage of aging cream more than 24 hr. was noted.

In a study of the effect of adding up to 0.6 percent of such substances as Kraftogen, dehydrated sodium caseinate, Dariloid, gelatin, Vegetable Gelatin, dehydrated egg albumin, and dehydrated egg yolk, the only marked benefit observed was the elimination of serum drainage by the use of 0.3 percent gelatin or 0.4 percent of either Dariloid or Vegetable Gelatin. All of these substances except Kraftogen and sodium caseinate reduced the overrun, and all except sodium caseinate and Vegetable Gelatin reduced the whipping ability of the cream. In general, the practice of adding such substances cannot be recommended.

Increasing the serum solids from 6.3 to 11 percent by addition of either skim milk powder or condensed skim milk slightly decreased the whipping ability and the serum drainage, but the benefits were not sufficiently great to justify the practice. Up to 15 percent sugar may be added at any time after the first minute of whipping without detrimental effect, but before pasteurization or immediately before whipping are the least desirable times to add sugar. Reconstituted cream did not compare favorably with ordinary cream in whippability or flavor. Homogenization, delayed cooling after pasteurization, or partial freezing (up to 50 percent solid) had no significant effects on the whipping quality of the cream. Total freezing before pasteurization destroyed the whipping properties of the cream, but total freezing after pasteurization had only a slight detrimental effect. Varying the source of protein in the cow's ration from vegetable to animal origin had no effect in this respect.

Controlling the flavor of butter, H. A. RUEHE (*Natl. Butter and Cheese Jour., 28 (1937), No. 4, pp. 20-22*).—In a report from the Illinois Experiment Station it is shown that the distillation of properly prepared butter starters yields a distillate rich in diacetyl and acetylmethylcarbinol which may be added to butter churned from unripened cream to produce the desired intensity of flavor. The flavoring qualities of the starter distillate can be standardized on the basis of its diacetyl content, since it is shown that little loss in diacetyl occurs over an extended storage period at 40° F. Most judges favor a butter containing the distillate flavor at the rate of less than 1 part of diacetyl to 200,000 parts of butter.

A further study of the factor in soybeans affecting the vitamin A value of butter, S. M. HAUGE, J. W. WILBUR, and J. H. HILTON (*Jour. Dairy Sci., 20 (1937), No. 2, pp. 87-91, fig. 1*).—With further reference to the factor in soybeans which exerts a suppressing action on the formation of vitamin A in butter (*Ill. S. R., 75, p. 245*), milking cows fed a standard basal ration of white corn, oats, alfalfa hay, and corn silage received various supplements in the form of

linseed oil meal, raw soybeans, expeller-type soybean oil meal, linseed oil meal plus 5 percent of either linseed oil or soybean oil, soybeans extracted with ether and alcohol, linseed oil meal plus ether extract from soybeans, and linseed oil meal plus alcoholic extract from soybeans. Milk samples from cows on the various rations were churned frequently, and the butter was assayed for vitamin A potency.

The vitamin A-suppressing factor was found to be present not only in the raw soybeans but also in the soybean oil and the soybean meal secured by either the expeller process or by chemical solvents. No suppressing action resulted from the presence of linseed oil in the ration, indicating that a factor in the soybean oil itself and not merely the presence of oil in the ration is the causative agent. Prolonged extraction of soybeans first with ethyl ether and then with ethyl alcohol failed to remove this factor completely. The feeding of alcoholic extract of soybeans did not produce a significant suppressing effect, indicating that this factor is not soluble in ethyl alcohol.

Diacetyl in cold-stored butters, II, C. R. BARNICOAT (*Jour. Dairy Res. [London]*, 8 (1937), No. 1, pp. 15-30, fig. 1).—Continuing this series of studies (E. S. R., 76, p. 387), experiments were conducted to study the derivation of diacetyl in starter butters and to follow the distribution of diacetyl and acetylmethylcarbinol during the butter-making process. Neutralization and pasteurization partially destroyed the carbinol fraction in cream, while the diacetyl content was practically unchanged. Both principles were retained in butter with the buttermilk fraction. Butter churned from sweet cream, mild starter cream, and high acid cream contained approximately 0.05, 0.3-0.4, and 1.5 p. p. m. of diacetyl, respectively, these contents remaining fairly constant during 3.5 months' storage at 14° F. The diacetyl content tended to increase when butter was held at 40° for several days after manufacture, which was attributed to the dehydrogenase activity of the starter organisms or their enzymes. Neither keeping quality nor vitamin A content of butter was affected by its diacetyl content.

The coagulation of milk with rennet: Some experiments with slow-renneting and soft-curd milks, F. H. McDOWALL, R. M. DOLBY, and A. K. R. McDOWELL (*Jour. Dairy Res. [London]*, 8 (1937), No. 1, pp. 31-52, figs. 7).—A series of experiments on the renneting of milk was started at the New Zealand Dairy Research Institute in 1930 because of occasional difficulties experienced with the rennet coagulation of milk in cheese factories. In general, such difficulties are not due to the tendency of some individual cows habitually to give soft-curd milk but rather to the spasmodic occurrence of soft-curd milk from herds generally producing normal milk. In these studies it has not been possible to establish any relationship between the composition of milk, particularly the calcium and phosphorus contents or the calcium:phosphorus ratio, and the type of curd obtained. The occurrence of slow-renneting soft-curd milk is more prevalent during periods of dry weather and certain districts are more liable to encounter such difficulties than others, but no causal factor for the sudden appearance of the trouble has been discovered.

The cheese yielding capacity of milk, and its relation to the method of payment for milk for cheesemaking, F. H. McDOWALL (*New Zeal. Jour. Sci. and Technol.*, 18 (1936), No. 3, pp. IX+137-364, figs. 45).—This extensive report includes a comprehensive review of the literature and the presentation of much original data. Comparisons are made of three systems of payment, namely, on a cheese test based on the casein-fat ratio in the milk, on a cheese test based on the content of casein plus fat in the milk, and simply on the fat content of the milk. Payment on the basis of the first-named test is considered

preferable. A system of payment embodying this test and also making allowance for the volume of milk handled by a plant and designated as a "costed cheese" system is recommended as one that would give an equitable distribution of payments to all suppliers.

The reactions and properties of annatto as a cheese colour, with particular reference to the chemistry of cheese discoloration, C. R. BARNICOAT (*Jour. Dairy Res. [London], 8 (1937), No. 1, pp. 61-73, figs. 3*).—This study shows that the intensity of color of commercial annatto solutions is not quite proportional to the dilution, that cheeses of high acidity tend to be deeper in color than the average, and that there is a proportionality between the color of cheese and the initial concentration of annatto in the milk. Methods are described for the extraction of the annatto color from milk products. It appears that the development of bleached and pink discolorations in cheese is due to an oxidation process, and the effect of oxidation on annatto solutions is indicated.

Limitations to the use of skimmilk powder and butter in the ice cream mix, P. S. LUCAS and J. JENSEN (*Michigan Sta. Quart. Bul., 19 (1937), No. 3, pp. 147-155*).—Mixes containing 20 percent of fat from butter whipped similarly to those made entirely from cream. When a high percentage of the fat content was supplied from butter, it was possible to obtain overrun more rapidly and to a somewhat greater degree, but the resulting ice cream showed an increasing tendency towards coarseness in texture and a lower resistance to melting. Aging mixes 48 hr. instead of 24 hr. increased whippability and improved the body and texture of the ice cream, particularly in mixes containing a large proportion of fat from butter, but did not affect melting properties. Spray-process skim milk powder and condensed skim milk appeared to be equally desirable as a source of serum solids, although use of the former gave mixtures possessing slightly better whipping qualities.

The Kniazeff method for finding the fat content of ice cream, D. H. NELSON (*Ice Cream Trade Jour., 32 (1936), No. 11, pp. 19, 20*).—In a critical study of this test method (E. S. R., 73, p. 236), the author points out certain difficulties encountered in performing routine tests. It is concluded that, while this method cannot replace the Mojonnier method, its simplicity, rapidity, and accuracy make it the choice of all the modifications of the Babcock method.

VETERINARY MEDICINE

[Report of work in animal pathology and parasitology by the Illinois Station] (*Illinois Sta. Rpt. 1935, pp. 93-100, 113, 114, 120-126, 127, 134-139, figs. 6*).—The work of the year reported upon (E. S. R., 74, p. 538), by R. Graham, E. H. Barger, F. Thorp, Jr., J. P. Torrey, E. Roberts, W. E. Carroll, J. A. Hunter, H. W. Johnson, L. E. Card, and J. H. Quisenberry, includes brief reference to the importance of control of shipping fever (hemorrhagic septicemia) of cattle, control work with Bang's disease, infectious abortion of swine, checking of Johne's disease of cattle through repeated testing and sanitation, swine resistance to hog cholera, control of parasites in horses, fatal encephalitic disease (commonly referred to as cornstalk disease of horses) (E. S. R., 76, p. 852), control of pullorum disease, control of laryngotracheitis of chickens through vaccination, hereditary resistance to pullorum disease (E. S. R., 74, p. 701), and the value of pigeon pox vaccine for control of fowl pox (E. S. R., 73, p. 403).

[Work in animal pathology by the Indiana Station] (*Indiana Sta. Rpt. 1936, pp. 24, 47, 67-70*).—Reference is made (E. S. R., 75, p. 840) to a characteristic organism thought to be one of the prime causative factors of abortion in guinea pigs, transmission of paralysis in chickens by inoculation,

immunization studies of Bang's disease, a study of the death loss in newborn pigs, hog cholera serum tests, urinary calculi in sheep, agglutination tests for infectious abortion in cattle and in hogs and for pullorum disease, encephalitis, worm parasites in quail, and results of diagnoses of animal diseases.

[Work in animal pathology and parasitology by the Tennessee Station] (*Tennessee Sta. Rpt. 1936*, pp. 25, 26, figs. 2).—Brief reference is made to control work with Bang's disease, by Jacob (E. S. R., 76, p. 102), and to the progress of poultry yard sanitation investigations, by Allen (E. S. R., 76, p. 695) and Jacob.

Report of the chief veterinary research officer, R. DAUBNEY (*Kenya Dept. Agr. Ann. Rpt., 1935*, vol. 2, pp. 130-162).—The work of the year (E. S. R., 76, p. 244) is reported upon at some length, particular attention being given to rinderpest, horse sickness, malignant catarrh of cattle, and swine influenza.

Paralysis in fowls and scrapie in sheep (a comparison), A. BROWNLEE (*Jour. Compar. Path. and Ther.*, 49 (1936), No. 4, pp. 328-335).—A comparative examination, presented with a list of 23 references to the literature on paralysis in fowls and scrapie in sheep, shows that the two diseases have many features in common.

Phagocytic activity of bone-marrow cells, I. F. HUDDLESON and M. MUNGER (*Soc. Expt. Biol. and Med. Proc.*, 35 (1936), No. 1, pp. 27-29; *abs. in Michigan Sta. Quart. Bul.*, 19 (1937), No. 3, p. 195).—The unusual opportunity offered by the vigorous opsonic response to the parenteral injection of antigenic fractions of *Brucella* cells for measuring the phagocytic activity of the various types of bone-marrow cells collected directly from the marrow, or as they are found in the peripheral blood in myelogenous leukemia, led to the observations here reported. The inference drawn from the studies is that, in infections where mature neutrophils are being rapidly destroyed, the bone marrow in an attempt to replace the cells destroyed forces out into the peripheral blood a high percentage of young forms which play little if any part in the protection of the individual against the infection. It would appear, therefore, that a too rapid or continuous shift to the left in peripheral blood cells of the myelogenous series is not a desirable condition. Its continuance impairs one of the important defensive mechanisms of the body during infection.

The chronic toxicity of carbon tetrachloride: Animal exposures and field studies, H. F. SMYTH, H. F. SMYTH, JR., and C. P. CARPENTER (*Jour. Indus. Hyg. and Toxicol.*, 18 (1936), No. 5, pp. 277-298).—In a study of the effect of the inhalation of carbon tetrachloride, it was definitely shown that an animal continuously exposed to from 50 to 400 p. p. m. of carbon tetrachloride soon regenerates originally damaged liver cells, and somewhat later regenerates damaged kidney cells while the exposure continues. The regenerated cells are more resistant than the original.

A liver preparation protecting against necrosis from chloroform or carbon tetrachloride administration, J. C. FORBES, R. C. NEALE, and J. H. SCHERER (*Jour. Pharmacol. and Expt. Ther.*, 58 (1936), No. 4, pp. 402-408, figs. 4).—This is a report upon a preparation of a liver concentrate which when injected into rats protects them to a marked extent against carbon tetrachloride and chloroform poisoning. The active principle is not choline, glucose, or the pernicious anemia factor.

The importance of cobalt in the treatment of certain stock ailments in the South Island, New Zealand, H. O. ASKEW and J. K. DIXON (*New Zeal. Jour. Sci. and Technol.*, 18 (1936), No. 2, pp. 73-92, figs. 9).—This contribution appears in two parts, with a preface by T. Rigg.

I. *Cobalt in the treatment of bush-sickness at Glenhope, Nelson, N. Z.*, H. O. Askew (pp. 74-84).—The author has found the use of cobalt chloride in drench form supplying 8 mg of cobalt per week to be completely successful in overcoming bush sickness at Glenhope. "The cobalt contents of drench materials employed in previous years [E. S. R., 73, p. 106] at Glenhope and in the Sherry Valley show agreement between high cobalt content and efficacy of the drench material. The high cobalt content of [Nelson soil] (Whangarei limonite (Reyburn)), when considered in conjunction with its efficacy in overcoming both Glenhope ailment (in Sherry Valley) and bush sickness (in North Island), suggests that cobalt is of great importance in the treatment of certain types of stock ailments in different parts of New Zealand. Data are not available to make a statement concerning the occurrence or otherwise of a cobalt deficiency in Glenhope pastures. It is known, however, that the cobalt content of Glenhope soil is particularly low (0.4 p. p. m. of cobalt, compared with 43 p. p. m. found in Nelson soil).

"The experiments detailed above do not prove, in the absence of knowledge of the cobalt content of pasture, that bush sickness is due to a deficiency of cobalt. Knowledge of the Glenhope ailment does definitely suggest, however, that it is caused by a mineral deficiency and that cobalt, so potent in overcoming the ailment, is probably present in deficient supply."

II. *Cobalt in the treatment of a sheep ailment, Morton Mains, Southland*, J. K. Dixon (pp. 84-92).—"A lamb sickness in Southland known as Morton Mains disease can successfully be controlled by the use of small quantities of cobalt. The evidence is in favor of the assumption that the effectiveness of certain soil drenches in the past was due to their cobalt content."

A reaction with iron compounds for the determination of *B. anthracis* and of its pathogenicity, E. DE ANGELIS (*Jour. Bact.*, 33 (1937), No. 2, pp. 197-206).—A new type of chemical test for the identification of the anthrax organism (*Bacillus anthracis*) is described.

"There are two procedures for obtaining the reaction, the direct and the indirect, and both give positive and negative results. Virulent cultures of *B. anthracis* give positive direct and indirect reactions, avirulent strains of *B. anthracis* give negative direct and positive indirect reactions, *B. subtilis* and other spore-bearing bacilli tested give negative direct and indirect reactions. There is a definite relationship between the strength of the reaction and the potency of the strains of *B. anthracis*. Little of the chemistry is known, but the fact is definitely established that a union of iron ions, whether ferric, ferrous, or both, with a product produced by the *B. anthracis* takes place. The substance seems to be derived from the gelatin portion of the medium. Out of some 30 different organisms tested, only *B. anthracis* has been found to give the reaction. Some bacteria which prevent anthrax when they are simultaneously injected into rabbits, guinea pigs, and mice with *B. anthracis* have also shown similar antagonistic action on this reaction."

The influence of tuberculosis upon the development of *Brucella abortus* infection, E. J. PULLINGER (*Jour. Hyg. [London]*, 36 (1936), No. 3, pp. 456-466).—The difficulty of isolating *B. abortus* from samples of contaminated milk by means of guinea pig inoculation has been found due in certain instances to the presence of tubercle bacilli in the inoculum, although this is deemed probably not the full explanation. "Following the simultaneous inoculation of virulent tubercle bacilli and *B. abortus* into guinea pigs, the latter infection generally failed to become established, whereas control animals inoculated under the same conditions with *Brucella*, but without tubercle bacilli, became infected. Results of the inoculation of the two organisms into opposite sides

of guinea pigs indicate a generalized as well as a local increase of resistance to *B. abortus*. It is suggested that the mononuclear cell reaction stimulated by the tubercle bacilli destroyed *B. abortus*."

The chemical constitution of the endo-antigen of *Brucella* cells, R. B. PENNELL and I. F. HUDDLESON (*Jour. Bact.*, 33 (1937), No. 1, p. 42).—A fraction constituting approximately 25 percent by weight of the dried cell, has been repeatedly isolated from organisms of the genus *Brucella*, the chemical analysis of which is briefly reported upon. It is responsible for the toxic action noticed upon intraperitoneal injection of *Brucella* cells into normal guinea pigs. The fraction precipitates immune serum in dilutions of from 1:400,000 to 1:1,000,000 and is actively antigenic.

Growth zones of the *Brucella* in semi-solid media, C. E. ZOBELL and K. F. MEYER (*Jour. Bact.*, 33 (1937), No. 1, pp. 44, 45).—It was found that "when semi-solid nutrient agar is seeded with a dilute suspension of *B. abortus* growth appears in a narrow zone 5 to 8 mm below the surface of the medium, the zone of recently isolated cultures being narrowest and deepest. *B. melitensis* growth zones are 2 to 5 mm below the surface, and *B. suis* multiplies on the surface to a depth of 4 or 5 mm. Studies on 17 recently isolated *B. abortus* cultures supplemented by observations on 450 stock cultures of all strains show that the depth and extent of the growth zones can be controlled to a certain extent by carefully adjusting the oxidation-reduction potential and pH of the medium."

The animal reservoirs of brucellosis, W. A. HAGAN (*Jour. Bact.*, 33 (1937), No. 1, pp. 39, 40).—A review of present knowledge of the animal reservoirs of the organisms of the *Brucella* group has led the author to consider it adequately proved that human infections may and do occur as a result of contacts with cattle, goats, and swine, and their secretions. While reliable information is quite limited, there seems to be no doubt but that the horse may sometimes act as a source of infection for other species of animals and for man. On the other hand, it seems quite improbable that sheep, dogs, and fowls ever play such a role, even though they may be invaded by *Brucella* and become reactors to the agglutination test for brucellosis.

The significance of the horse in brucellosis, C. M. CARPENTER and R. A. BOAK (*Jour. Bact.*, 33 (1937), No. 1, p. 40).—Epidemiological studies of equine brucellosis indicate that the horse may be a more significant source of infection for man and cattle than is generally recognized. "The examination of serum for *abortus* agglutinins from 347 horses, taken mostly from four stables, showed that 27 percent had a titer of 1:25, 14 percent a titer of 1:50, and 8 percent a titer of 1:100 or higher. Tests on a group of mares, repeated over a period of 2 yr., disclosed that some of them had become infected without presenting clinical evidence of brucellosis. A few of the mares that developed high titers became temporarily sterile. Frequently the titer at the first test was 1:25, while at successive examinations it increased to 1:100 or higher, only to subside later to 1:25 or to disappear. These mares had been in contact with cattle with Bang's disease. Examination of the milk from 5 of the reacting mares that foaled normally revealed no evidence of *Brucella abortus* infection.

"The serum from 2 of 3 horses with fistulous withers reacted at titers of 1:200 and 1:100, respectively, while the remaining 3 contained no *B. abortus* agglutinins. A bovine strain of *B. abortus* was isolated by guinea pig inoculation from the purulent exudate of 1 of these horses. Two children who had contact with this horse developed serious undulant fever."

Results of passage of human and monkey strains of *Brucella melitensis* through pregnant heifers, D. E. WILSON and S. A. EVANS (*Jour. Compar. Path. and Ther.*, 49 (1936), No. 4, pp. 336-339).—A report is made of a case of apparent

mutation of *B. melitensis* (human-monkey passage) to *B. abortus* by passage through a pregnant heifer. Subsequent attempts to repeat this mutation failed, using the same strain and a known human *B. melitensis* strain. That the heifer used in the original experiment carried a latent *B. abortus* infection and that agglutination failed to reveal its presence is considered possible.

The detection of antigenic variants of *Brucella* by means of the opsonocytophagic test, M. MUNGER, I. F. HUDDLESON, and S. WAKEMAN (*Jour. Bact.*, 33 (1937), No. 1, pp. 48, 44).—The opsonocytophagic test has been found to offer an accurate and simple means of detecting antigenic variants in the *Brucella* groups. The employment of this test for the detection of individuals susceptible or immune to *Brucella* infection requires the use of a normal culture.

A study of *Brucella* infection and immunity in a large county hospital, I. F. HUDDLESON, S. E. GOULD, M. MUNGER, and D. M. PAULSON (*Jour. Bact.*, 33 (1937), No. 1, p. 44).—In a study of *Brucella* infection, immunity, and susceptibility of 8,124 hospital inmates, 10.3 percent gave a positive brucellergin skin test. Data were obtained which show the comparative value of the serum agglutination test and the intradermal test in determining *Brucella* infection and immunity, and which show the accuracy of the diagnostic tests on a large group of individuals retested after 7 mo.

Diagnosis of undulant fever: The opsonocytophagic, allergic, and agglutination reactions, A. E. KELLER, C. PHARRIS, and W. H. GAUB (*Jour. Amer. Med. Assoc.*, 107 (1936), No. 17, pp. 1369-1373, fig. 1).—The data presented are said to agree with those reported by Huddleson et al. from the Michigan Experiment Station (*E. S. R.*, 70, p. 527; 72, p. 382) on *Brucella* infections of individuals who are either in the active stage of undulant fever or who have recovered and in persons who are living or working under conditions of exposure to this group of organisms.

The observations indicate that the intracutaneous test may be used to determine a state of allergy resulting from *Brucella* infection, and in determining the presence of infection with *Brucella* in individual patients or the incidence of this infection in groups of the population. It gives no indication of the immunity status of the patient, but this may be determined by the opsonocytophagic test. It is possible with the use of these two tests to ascertain whether individuals are susceptible, infected, or immune with regard to undulant fever.

Priority among American physicians in demonstrating the cause of grain itch: Tardy credit therefor given to Dr. Lyman Talmage Rawles, H. E. KITTREDGE (*Jour. Amer. Med. Assoc.*, 107 (1936), No. 26, pp. 2109-2115).—The early history of the straw itch mite as the cause of dermatitis is reported upon, with 26 references to the literature.

A culture medium for *Erysipelothrix rhusiopathiae*, L. R. VAWTER (*Jour. Amer. Vet. Med. Assoc.*, 90 (1937), No. 5, pp. 635, 636).—The author has recently observed in the course of work in Nevada that liver digest solution enriched by the addition of 2 to 4 percent sterile, normal horse serum proved superior to any medium previously recommended for *E. rhusiopathiae*. The medium, which consists of liver digest solution (basal medium), bacto-peptone 1 percent, and sodium chloride 0.5 percent, is adjusted to a pH of 7.6 or 7.7 before sterilization, distributed in tubes or flasks, and sterilized in the autoclave for 20 min. at 15-lb. pressure. After sterilization from 2 to 4 percent of sterile, normal horse serum is added and then incubated for 48 hr. at 37° C. to check on sterility.

It has been found that old stock strains as well as recently isolated strains of the organism grow rapidly in this medium, which has proved excellent for the recovery of either this organism or *Corynebacterium pyogenes* from

polyarthritides lesions in lambs and swine. "Broth cultures attain their maximum growth and turbidity in 24 hr. at 37° without sedimentation. Gram-positive diphtheroid forms predominate at this time with occasional filamentous forms. The density ranges from 2.5 to 3 cm as measured with a Gates opacimeter.

"Agar slants or plates may be prepared by dissolving bacto-agar in the above described fluid media, 2 to 4 percent sterile horse serum being added aseptically after sterilization. Colonies appear on serum-enriched, liver-digest agar after incubation for 24 hr., reaching their maximum size of 0.5 mm in about 48 hr., and are larger than on other media heretofore recommended. Rough and smooth colonies can be readily distinguished on plate cultures after incubation for 48 hr.

"Twenty-four-hour, serumized, liver-digest cultures of *E. rhusiopathiae* can be used as whole culture antigen for the agglutination test by diluting with sterile liver-digest solution, pH 7.6, to a density of 5 cm (Gates scale) and the addition of 0.5 percent phenol, the diluted and phenolized broth cultures being allowed to remain at room temperature for 24 hr. before being used in the agglutination test. Definite agglutination occurs with positive serums after incubation for 8 hr. at 37° and is complete in about 16 hr. Centrifugation of the agglutination tubes is not necessary, as agglutination is sharply defined and more easily read than is the case with some forms of agglutination antigen heretofore recommended.

"Comparison was made using saline suspensions of *E. rhusiopathiae*, alcohol-treated antigen of Deem, and the whole culture antigen described. Commercial anti-swine-erysipelas serum and positive serums from sheep convalescent from erysipelas infection agglutinated all of the antigens in the same dilutions."

Experiments on immunisation against *Pasteurella septica* infection, F. W. PRIESTLEY (*Jour. Compar. Path. and Ther.*, 49 (1936), No. 4, pp. 340-347).—A description is given of a method of preparing a vaccine from virulent capsulated *P. septica*. It is shown that this vaccine is able to protect mice against a dose of organisms sufficient to kill all controls and all mice inoculated with the type of vaccine containing only somatic antigen.

Rabies and its transmission by naturally infected haematophagous bats, S. TORRES and E. DE QUEIROZ LIMA (*Rev. Dept. Nac. Prod. Anim. [Brazil]*, 32 (1935), No. 1-3, pp. 1-55, pls. 12; *Eng., Fr. abs.*, pp. 43-50).—Experiments conducted have led the authors to conclude that in the focuses of epizootic rabies as well as out of them hematophagous bats are found that are carriers of the virus. In the inoculations reported upon, the incubation period varied from 10 or 13 days to as long as 202 days in the case of a bat caught in the State of Mato Grosso.

Serological variants of *Salmonella typhi-murium*, with special reference to *S. typhi-murium* var. *binns*, P. R. EDWARDS (*Jour. Hyg. [London]*, 36 (1936), No. 3, pp. 348-354).—Studies of several cultures of *S. typhimurium* *binns* at the Kentucky Experiment Station revealed the fact that all contained specific components characteristic of *S. typhimurium*. "These cultures lacked the somatic factor V. It is proposed, therefore, to amend the antigenic formula of *S. typhimurium* var. *binns* from IV, V:—1, 2, 3, to IV:1:1, 2, 3. Under the emended variety would also be included the organisms described by [F.] Kauffmann² as *S. typhimurium* var. *copenhagen* and by Edwards [*E. S. R.*, 74 p. 548] as *S. aertrycke* var. *storr*."

² *Ztschr. Hyg. u. Infektionskrank.*, 116 (1934), No. 4, pp. 368-384.

Notes on the survival of the eggs and free-living larvae of sclerostomes on pasture, I. W. PARNELL (*Sci. Agr.*, 16 (1936), No. 7, pp. 391-397; *Fr. abs.*, p. 397).—Physical and chemical tests of the bursate nematodes of horses and sheep, which form one of the major sources of loss to the owners of these animals, are reported. A list of 22 references to the literature is included.

On a pleuropneumonia-like organism in lung lesions of rats, with notes on the clinical and pathological features of the underlying condition, E. KLIENEBERGER and D. B. STEARNS (*Jour. Hyg. [London]*, 37 (1937), No. 1, pp. 143-152, pl. 1).—The authors have found *Streptobacillus moniliformis* (i. e., *L.* plus *Streptobacillus*) to be a frequent inhabitant of the nasopharynx of rats with lung lesions, and that it may secondarily invade the lungs since it is found in severe cases together with the *L.* organism.

Biochemical and serological characteristics of streptococci of bovine origin, W. N. PLASTRIDGE and S. E. HARTSELL (*Jour. Bact.*, 33 (1937), No. 1, pp. 24, 25).—In continuation of earlier work by the [Connecticut] Storrs Experiment Station (E. S. R., 74, p. 846), biochemical tests and the precipitin test of Lancefield employed in determining the characteristics of streptococci (*Streptococcus agalactiae*) obtained from freshly drawn milk samples are reported upon. The results obtained are considered to indicate that, while either biochemical or serological tests alone may give satisfactory results, both tests are necessary for the final identification of streptococci of bovine origin.

Studies on hemolytic streptococci.—III, *Streptococcus equi* and related strains, A. C. EVANS (*Jour. Bact.*, 32 (1936), No. 5, pp. 541-556).—In continuation of earlier studies (E. S. R., 76, p. 101), the author presents a review of the literature on *S. equi* and describes the characters of the species as observed in 20 cultures isolated in various parts of the United States and in Denmark (4 strains).

"Eleven strains agreed in every character. One of them, No. 725, was chosen as the type strain. Nine strains are regarded as variants because they differ from the type strain in one or more characters and yet resemble *S. equi* more closely than any other species. In a collection of about 400 strains from human disease sources, not one was classified as *S. equi*. The human strains which had been reported by other investigators to be *S. equi* were found to belong to other groups."

A list is given of 31 references to the literature.

Chemotherapy in streptococcal infections (*Jour. Amer. Med. Assoc.*, 108 (1937), No. 1, pp. 48, 49).—This is a summary of recent findings in therapeutic work with virulent hemolytic streptococci of human origin in which Prontylin or Prontosil Soluble has been used.

Para-amino-benzene-sulfonamide and its derivatives: Experimental and clinical observations on their use in the treatment of beta-hemolytic streptococcal infection.—A preliminary report, P. H. LONG and E. A. BRIS (*Jour. Amer. Med. Assoc.*, 108 (1937), No. 1, pp. 32-37, fig. 1).—Following a brief reference to the recent observations of numerous European investigators that p-aminobenzenesulfonamide (including Prontylin) and certain of its chemical derivatives (including Prontosil) exert a specific chemotherapeutic effect in β -hemolytic streptococci infections, the results of experimental treatment of mice are reported, the details being given in tables. It is concluded that the careful clinical use of this dye and its derivatives in infections due to β -hemolytic streptococci is warranted.

The mode of action of p-aminobenzenesulphonamide and Prontosil in haemolytic streptococcal infections, L. COLEBROOK, G. A. H. BUTTLE, and R. A. Q. O'MEARA (*Lancet [London]*, 1936, II, No. 23, pp. 1323-1326).—It is pointed out that no satisfactory explanation has yet been given for the unmistakable

effect of Prontosil (now known as Red Prontosil) and of Prontosil Soluble in controlling hemolytic streptococcal infections in the mouse, and for the apparently analogous curative effects reported in man. The present paper deals with a number of new facts which have recently come to light.

"p-Aminobenzenesulfonamide has a bacteriostatic and bactericidal action against small numbers of hemolytic streptococci in culture medium and in blood. Prontosil is inactive, but on reduction an active substance is produced. Following administration of the sulfonamide, or of Prontosil, to man and animals their blood is bactericidal to hemolytic streptococci."

A list is given of 12 references to the literature relating to the subject.

Studies on tuberculosis, J. BARBOSA DA CUNHA (*Rev. Dept. Nac. Prod. Anim. [Brasil]*, 2 (1935), No. 1-8, pp. 115-126; *Eng. abs.*, pp. 123-126).—These studies relate to (1) the isolation of the human type of the tuberculosis bacillus from the muscle of a pig and (2) the occurrence of tuberculosis among cattle and swine in the States of Rio Grande do Sul, Paraná, São Paulo, and Rio de Janeiro.

Sources of infection and seasonal incidence of tularaemia in man, E. FRANCIS (*Pub. Health Rpts. [U. S.]*, 52 (1937), No. 4, pp. 103-113, pls. 2, figs. 2).—Included in this contribution is a reference to the mammal, insect, and acarid vectors of *Bacterium tularense*, which is known to have reached man directly from over 20 animal sources. Discovered in ground squirrels in Tulare County, Calif., in 1910, human cases have since been recognized in 46 States of the Union and in the District of Columbia.

Ixodes ricinus californicus (Banks), a possible vector of *Bacterium tularense*, G. E. DAVIS and G. M. KOHLS (*Pub. Health Rpts. [U. S.]*, 52 (1937), No. 10, pp. 281, 282).—A record is made of the collection of two naturally infected adults of *I. ricinus californicus* from a recently dead jack rabbit (*Lepus californicus californicus*) near Grants Pass, Oreg., with indications that this tick may be a vector of the causative organism of tularaemia.

North American records of the tick *Ixodes ricinus californicus* (Banks), G. M. KOHLS and R. A. COOLEY (*Pub. Health Rpts. [U. S.]*, 52 (1937), No. 10, pp. 282-284).—The known host and locality records of *I. ricinus californicus*, a common tick of the Pacific coast region and thought to be a vector of *Bacterium tularense*, are here assembled.

The botulism of bovines [trans. title], P. ROSSI and F. VIGEL (*Rev. Gén. Méd. Vét.*, 45 (1936), No. 539, pp. 641-670).—The authors have found botulism to occur in the bovine in France, it being manifested by symptoms similar to those in man. A polyvalent serum and immunization by antitoxins A and B have been used as prophylactic and remedial measures.

A list is given of 50 references to the literature.

The isolation of *Brucella abortus* from the milk of cows with negative blood reactions to the agglutination test, T. M. DOYLE and F. BECKETT (*Jour. Compar. Path. and Ther.*, 49 (1936), No. 4, pp. 320-327).—In the examination of milk samples from 309 nonreacting cows in 17 *B. abortus*-infected herds by guinea pig inoculation for the presence of the organism, *B. abortus* was isolated from the milk of two cows which had negative blood titers in dilutions of from 1:25 to 1:200. When 684 cows from 17 commercial dairies situated in the south of England were tested for the presence of *Brucella* agglutinins, the average herd infection was found to be about 35 percent.

The value of vaccination with live culture of *Br. abortus* for the prevention of abortion, H. E. KEYLOCK (*Jour. Compar. Path. and Ther.*, 49 (1936), No. 4, pp. 350-359).—In experiments conducted, the details of which are presented in tables, viable abortion vaccine administered to adult animals increased the number of full-term calves by 6.32 percent, decreased abortion by 4.32 percent,

and decreased the retention of the placenta by 2.59 percent. The difference in favor of vaccination is so small that it is thought that over a further length of time it might easily be reversed and that vaccination confers very little, if any, immunity.

In the work with heifers there was such an increase in the number of abortions and sterility that vaccination has been discontinued.

Chronic mastitis, G. J. HUCKER (*Conn. Dairymen's Assoc. Rpt. Proc.*, 55 (1936), pp. 112-121).—This practical contribution from the New York State Experiment Station was presented as an address at Hartford, Conn., in January 1936.

Dextrose-fermenting aerobes in the spleen and lymph glands of rinderpest infected cattle, M. M. ROBLES (*Philippine Jour. Anim. Indus.*, 4 (1937), No. 1, pp. 5-11).—Records having shown that of 98 serials of rinderpest vaccine prepared and tested in the laboratory of the Philippine Bureau of Animal Industry 3 contained dextrose-fermenting aerobes, a study was conducted to determine the incidence, type, and behavior of such bacteria. It was found that their incidence in the spleen and lymph glands of rinderpest-infected cattle was highest in the visceral and lowest in the body lymph glands, with the spleen occupying an intermediate position. All of the strains isolated belonged to the *coli-aerogenes* group, which points to the digestive tract as the most probable source of contamination. Of those isolated, only 2 proved fatal to guinea pigs. They were able to produce local and general disturbances in cattle. However, none of the strains was able to survive a desiccation of 2 mo. in the ice chest or the disinfecting action of 0.4 percent chloroform for 10 days, thus making the elimination of such contamination feasible under favorable conditions.

Trichomoniasis or trichomonad abortion in cattle, H. SCHMIDT (*Jour. Amer. Vet. Med. Assoc.*, 90 (1937), No. 5, pp. 608-618).—As a contribution from the Texas Experiment Station, a summary is given of the present status of knowledge of this disease, with a list of 29 references, followed by a brief account of observations on a large dairy herd in Texas in which the disease occurred.

The presence of avian tubercle bacilli in the lymph-nodes of cattle, J. McCARTER, E. G. HASTINGS, and B. A. BEACH (*Jour. Amer. Vet. Med. Assoc.*, 90 (1937), No. 5, pp. 619-626).—In examinations made by the Wisconsin Experiment Station of the tuberculous lymph nodes of 28 tuberculin-reacting cattle, examined by cultural methods and by guinea pig inoculation for the presence of acidfast micro-organisms, 3 were found to be infected with avian tubercle bacilli, 23 with mammalian tubercle bacilli, and there were negative results from 2. It is concluded that infection with avian tubercle bacilli is probably responsible for part of the tuberculin reactions in lesion as well as in no-visible-lesion cattle in Wisconsin.

Herrold's egg yolk-agar medium has been found to be completely efficient for the culture of bovine tubercle bacilli from tuberculous guinea pig tissues, but is not quite so satisfactory as the inoculation of guinea pigs for the detection of bovine tubercle bacilli in the tuberculous tissues of cattle.

Artificial thallium moult in sheep, N. A. IRWIN (*Jour. Genet.*, 33 (1936), No. 2, pp. 305-313, pls. 5).—Accounts are given of the artificial molting of fine wool as well as mixed wool sheep, at the Soviet State Farms in Crimea, by thallium treatments.

Listerella infection associated with ovine encephalitis, E. JUNGHEER (*Jour. Bact.*, 33 (1937), No. 1, pp. 112, 113).—A report is made of five cases of meningoencephalitis associated with *Listerella* infection, observed by the [Connecticut] Storrs Experiment Station in a flock of 200 purebred sheep. "Diagnosis was based in one instance on clinical examination alone, in two on histologic

and bacterioscopic evidence, and in two entirely on cultural isolation of a *Listerella* organism from the affected areas. Pathologically the disease was characterized by mononuclear infiltrations in the regional meninges and by perivascular areas and central polynuclear foci in the medulla oblongata. Similar disturbances were produced in mice by intranasal injection of brain suspension and small doses of *Listerella* culture, while filtered brain material was innocuous. Comparatively large culture doses injected intranasally produced in mice a rapidly fatal septicemia, and in sheep a marked thermic and agglutinative response followed by recovery. Sheep receiving intracarotid injections of *Listerella* culture succumbed to hemorrhagic meningitis. Primary isolation of the *Listerella* organism from field cases was effected on blood sugar agar slants and egg meat medium; subcultures on liver agar plates produced a characteristic milky, slightly opalescent, round, entire colony. Except for minor differences in delayed biochemical reactions, the ovine strains could not be distinguished from two human and one ovine reference strains by morphologic, cultural, agglutination, and agglutinin absorption tests."

Infectious enterotoxaemia and the *Clostridium welchii* group, with special reference to so-called pulpy kidney in lambs, D. A. GILL (*New Zeal. Jour. Sci. and Technol.*, 18 (1936), No. 2, pp. 106-119, fig. 1).—In this contribution the author discusses the general nature of enterotoxaemia and the work that led to its discovery, summarizes the existing knowledge of the causal organism, and deals with methods of prevention and control of the disease.

On the intestinal worms of goats in Nanking, H. W. WU and T. P. HU (*Sinensia*, 6 (1935), No. 6, pp. 698-700).—The trematode *Paramphistomum cervi* (Shrank) and the nematodes *Haemonchus contortus* (Rud.), *Oesophagostomum venulosum* (Rud.), and *Trichuris ovis* (Abildg.) were found in the alimentary tracts of goats reared in the vicinity of Nanking that were examined in the spring of 1935.

A comparison of the tube and plate methods of testing for Bang's disease in elk, A. M. LEE and M. E. TURNER (*Jour. Amer. Vet. Med. Assoc.*, 90 (1937), No. 5, pp. 637-640).—The results of tests made (1) with the official tube test and (2) with two commercial plate antigens which had been found to give reasonable agreement with the tube test in cattle are reported. The tests were applied to blood samples obtained in December 1935 from 132 elk that were being slaughtered in the herd-reduction program in Wyoming, the details being given in tables. Those which gave complete agglutination in the 1:100 dilution or higher were considered reactors, and those showing complete or incomplete agglutination in the 1:50 dilution were classed as suspects.

"There were 28 reactors (19 percent) out of the 143 tested by the tube test. There were 19 (13 percent) reactors to the plate test with antigen 1, and there were 22 reactors (15 percent) with plate antigen 2. There were 17 suspects to the tube test, 14 to the plate test with antigen 1, and 11 with plate antigen 2. Failure to get reasonable agreement between tube and plate tests with one or both antigens was encountered in 19 of the 143 samples tested. This was over 13 percent." Strong reactors to the tube test were negative to the plate test. In some samples strongly positive to the tube test, plate antigen 2 gave positive results while plate antigen 1 gave negative or suspicious results. On the other hand, 1 sample was positive in dilutions of 1:200 by the tube test and with plate antigen 1, whereas plate antigen 2 gave a positive reaction in only the 1:50 dilution.

The 4 other samples of the 19 mentioned above which were strong reactors to the tube test were tested with 4 plate antigens which gave reasonable agreement with the tube test in cattle.

The tube test with a 72-hr. incubation and a polyvalent antigen was found to be considerably more accurate than the plate or rapid test.

Posterior paralysis in swine, L. P. DOYLE (*Jour. Amer. Vet. Med. Assoc.*, 90 (1937), No. 5, pp. 656-660, figs. 5).—A practical summary of information, contributed from the Indiana Experiment Station.

Diagnosis of hog cholera by an intradermal reaction [trans. title], A. DONATIEN and F. LESTOQUARD (*Rev. Vét. [Toulouse]*, 88 (1936), Dec., pp. 657-668).—Observations reported have led to the perfection of a technic for the diagnosis of hog cholera by an intradermal reaction. The antigen must contain both the hog cholera virus and castor oil if positive reactions are to be obtained.

Distribution of hog-cholera virus among fractions of virus blood, W. C. POWICK (*Jour. Agr. Res. [U. S.]*, 54 (1937), No. 3, pp. 221-233).—Experiments conducted by the U. S. D. A. Bureau of Animal Industry at Ames, Iowa, in 1929 in an attempt to compare the minimal infective doses of the cells, serum, and certain other fractions of virus blood and to measure the extent to which blood cells of normal pigs can adsorb hog cholera virus from infectious serum are reported. The virus blood was obtained from experimentally inoculated pigs with acute hog cholera. The test pigs were susceptible animals, bred on nearby farms from susceptible sows. Most of the virus of the cholera blood was associated with the cellular elements. The erythrocyte stroma carried an important part of the virus in relatively high concentration, and cells from normal pig blood readily and firmly adsorbed much of the virus from virus serum. Probably no important part of the whole quantity of virus was associated with the leucocytes of hog cholera blood.

Hog cholera is transmissible to the sheep and goat [trans. title], H. JACOT (*Compt. Rend. Acad. Sci. [Paris]*, 203 (1936), No. 23, pp. 1297-1299).—The author has found that hog cholera is readily transmissible through inoculation to the sheep and goat, and that these animals can also be infected by simple cohabitation with affected swine. While the disease is usually inapparent in small ruminants, the virus may be discharged with the excrement.

Preliminary observations on the infectivity of *Ascaris lumbricoides* to swine, P. A. CLAPHAM (*Jour. Helminthol.*, 14 (1936), No. 4, pp. 229-232).—The results obtained from the ingestion of eggs of *A. lumbricoides* by pigs bottled from birth and free from infection are briefly reported upon.

Treatment of impaction in the horse with lentin, the new rapid-acting cathartic, M. V. BURGETT and G. W. BARDENS (*Jour. Amer. Vet. Med. Assoc.*, 90 (1937), No. 5, pp. 646-655).—The authors have found lentin (carbaminoxylcholine chloride), first introduced into veterinary practice in 1932, to be more effective than arecoline in colic and impaction in the horse. It is more regular and surer in action and is safer than other rapid-acting purgatives—arecoline, escrine, or barium chloride, because it does not depress the circulation.

***Brucella abortus* in horses**, A. W. DEEM (*Jour. Bact.*, 33 (1937), No. 1, pp. 40, 41).—Brief reference is made to *abortus* agglutination titers which were determined on the blood serums of 189 horses. Thirty-four of these had either fistulous withers or poll evil, or both, and 28 gave positive reactions in serum dilutions of 1:50 or higher. Of the other 155 horses examined, 29 had positive tests in the same range of serum dilutions. Of 103 apparently normal horses in the local field artillery unit, 10 were positive for agglutinin in dilutions of 1:50 or 1:100, none higher. "By direct isolation we were able to obtain *B. abortus* in pure culture from 9 of 15 samples of material obtained from as many previously unopened fistula cases, and from 1 of 2 specimens of synovial fluid in other bursitis conditions. A simplified method for isolating *B. abortus*

from otherwise uncontaminated material is given. We were unable to recover *B. abortus* from pus from any of 5 cases of fistulous withers from 1 to 6 weeks after they were opened."

Transmission of equine encephalomyelitis (California virus) to the vulture (*Vultur fulvus* Briss.) [trans. title], P. REMLINGER and J. BAILEY (*Compt. Rend. Soc. Biol. [Paris]*, 123 (1936), No. 30, pp. 562, 563).—The common vulture of Morocco was found to be susceptible to the western type of the equine encephalomyelitis virus, having succumbed on the fourth day following subdural inoculation.

Infectious tracheo-bronchitis of the horse (*Jour. Roy. Army Vet. Corps*, 7 (1936), No. 4, pp. 188-195).—A general review of this affection of the horse is followed by a discussion of its clinical relation to known epizootics.

Treatment of experimental surra in native horses by means of the combined suboccipital-intravenous injections of "Bayer 205", L. M. YUTUC (*Philippine Jour. Anim. Indus.*, 3 (1936), No. 6, pp. 459-462).—In experiments conducted with a view to determining the efficiency of simultaneous suboccipital and intravenous injections of Bayer 205, commonly known as Naganol, three of the seven animals used were able to stand the complete sets of injections, but relapses were noted during and after the treatment. "The dose for suboccipital injection was 0.045 mg in 0.1-percent concentration and for the intravenous injection it was 15 mg in 10-percent solution per kilogram live body weight, respectively. In general the treatment was given every 14 days until three simultaneous injections were administered. . . . Two animals died after the initial injections, while one was killed in extremis after a short period following the last injections. These results indicate that the suboccipital-intravenous injections of Bayer 205, beyond prolonging the course of the infection, are of not much value in the treatment of surra with nervous complications."

Tolerance of naganol (Bayer 205) by horses, S. C. J. BENNETT (*Jour. Compar. Path. and Ther.*, 49 (1936), No. 4, pp. 304-309, fig. 1).—The author has found that in treatment for trypanosomiasis most horses can tolerate naganol to a far greater extent than commonly believed, and that, in spite of undesirable reactions to the drug in many cases they can be maintained in workable condition for some months at least. "No dose of naganol lower than 2 g will check a trypanosomiasis relapse, and the outcome in a horse which is not inherently intolerant of the drug will depend on whether or not the trypanosome infection becomes so severe, in the sense that relapses occur at short intervals, that an intolerable intensity of treatment becomes necessary."

The pathology of *Crotalaria spectabilis* Roth seed poisoning in the domestic fowl, M. W. EMMEL (*Jour. Amer. Vet. Med. Assoc.*, 90 (1937), No. 5, pp. 627-634, fig. 1).—A report is made of crotalaria seed poisoning studies of the fowl at the Florida Experiment Station, in continuation of those of Thomas (*E. S. R.*, 72, p. 391). Innumerable petechiae in the serous membranes and visceral fat as well as a dark liver, marbled in color, were the outstanding lesions in the acute type. In the chronic type of poisoning necrotic enteritis, ascites, and anemia were observed, the liver often appearing as in the acute type of poisoning. Passive congestion, edema, cloudy swelling, and occasionally foci of necrosis in the parenchymatous tissues, smooth muscle, and serous membranes dominate the histopathology.

Infectious enterohepatitis, A. J. DURANT (*Jour. Amer. Vet. Med. Assoc.*, 90 (1937), No. 5, pp. 596-607, figs. 2).—A practical summary of information, contributed from the Missouri Experiment Station.

Primary irido-cyclitis in fowls: A condition distinct from the eye lesions occurring in neuro-lymphomatosis, H. P. BAYON (*Jour. Compar. Path. and*

Ther., 49 (1936), No. 4, pp. 310-319).—The occurrence of outbreaks of iridocyclitis, involving relatively large numbers of fowls, without the appearance of paralysis before, during, or after the development of the eye lesions, suggests that iridocyclitis is not always due to neurolymphomatosis but may occur as a separate disease. "Such birds with primary iridocyclitis, when placed in single-pen cages where they have easy access to food and drink, notwithstanding their blindness will go on laying throughout the season, while fowls with neurolymphomatosis either do not come into lay at all or cease laying the moment the disease is manifest. Though it is admitted that there is no clear-cut difference between the anatomical lesions in the eyes of birds with primary iridocyclitis when compared with those detectable in the eye affection occurring in the course of fowl paralysis, yet the different occurrence and course of the two ailments may be allowed to suggest a distinction in pathology between the localized affection of the eye when occurring alone and the generalized lymphomatosis seen in fowl paralysis. From the standpoint of veterinary medicine it is advisable to treat cautiously the presence of 'pearly eyes' in breeding birds, since it is not always possible to distinguish in the living, on the spot, certain harmless varieties of 'pale eyes' from early and yet dangerous pathological lesions."

Cysteine-gelatin as a differential medium for *Salmonella pullorum* and *Salmonella gallinarum*, W. R. HINSHAW and L. F. RETTGER (*Soc. Expt. Biol. and Med. Proc.*, 35 (1936), No. 1, pp. 44-46).—A brief report is made of work with cysteine gelatin as another medium for the differentiation of *S. pullorum* from *S. gallinarum*. All 55 of the *S. gallinarum* strains of fowl origin gave a definite positive reaction in cysteine gelatin in the form of a distinct yellowish-white turbidity when incubated at 37° C. for from 24 to 72 hr. The nature of this turbidity has not been definitely determined, but it is not due to profuse growth of the organisms. When stab cultures of the same strain were incubated at 0°, a zone of turbidity developed at the surface and along the line of puncture in from 48 to 72 hr. In shake cultures a similar zone was found around each individual colony. All of the 120 strains of *S. pullorum* of fowl origin produced no changes in the cysteine gelatin, either when incubated at 37° or at 20°. The reactions of the 11 strains of *S. typhi*, all of human origin, in cysteine gelatin more nearly resembles those of *S. pullorum* than *S. gallinarum*.

A composite drop-reaction sheet for the spot method of conducting the whole-blood test for pullorum disease, D. E. STOVER (*Jour. Amer. Vet. Med. Assoc.*, 90 (1937), No. 5, pp. 661-664, fig. 1).—A description is given of a composite drop-reaction sheet devised with a view to eliminating an outstanding flaw in the spot method of conducting the whole blood test for pullorum disease. The sheet consists of a piece of drop-reaction filter paper and a piece of lens paper placed face to face and attached at the corners with paste.

Titre fluctuation in agglutination tests for pullorum disease in hens, B. H. EDMINGTON (*Poultry Sci.*, 16 (1937), No. 1, pp. 15-18).—Following a brief reference to the literature, this contribution from the Ohio Experiment Station reports upon an investigation in which adult hens showing different titer limits in agglutination tests for pullorum disease were assembled in two groups. In one group the fowls were isolated in individual cages; in the other they were held as a unit in a single pen. The results of the agglutination tests, which were run at monthly intervals over a period of 1 yr., are reported in detail in tables. Titer fluctuations varying as to time of occurrence and degree were observed in each group. There appeared to be no significant difference in sustained trends of titer variations of the two groups that could be attributed to the manner in which the fowls were maintained.

A study of immunity produced by infection with attenuated culture-strains of *Histomonas meleagridis*, E. E. TYZZER (*Jour. Compar. Path. and*

Ther., 49 (1936), No. 4, pp. 285-303).—In summarizing studies conducted in continuation of those noted (E. S. R., 71, p. 395), the author reports that various culture strains of *H. meleagridis* have shown no uniformity in regard to the rate of decrease in pathogenicity. "Thus while pathogenicity was lost in 1.5 yr. in one strain, another strain was still mildly pathogenic after 3 yr. Strains which have become nonpathogenic retain for a time well-marked immunizing properties when established in the ceca, but may gradually lose these properties and later on furnish no more than slight or partial protection against inoculation with fully pathogenic strains. Histological study of successive stages of the pathological process resulting from the invasion of the cecal wall by *Histomonas* has revealed qualitative as well as quantitative differences in the reaction of the chicken to different culture strains. On comparing the reaction of partially immunized and those of nonimmunized chickens to pathogenic *Histomonas*, the lesions are found to be microscopically similar, differing only in extent. In birds completely immunized, as judged by gross appearances when killed at appropriate periods after the test inoculation, no invasion of the tissues has been demonstrated microscopically. Notwithstanding the lack of distinctive histological differences in the character of the reactions of the partially protected chickens as compared with those of controls, the modification of the infection in the former is clearly shown in the shortening of the course of infection, in the occurrence of delayed infections, and in the marked limitation of the area of the cecal wall invaded."

The occurrence of *Salmonella*, Senftenberg type, in a disease of turkeys, P. R. EDWARDS (*Jour. Bact.*, 33 (1937), No. 2, pp. 193-195).—Two cultures isolated from young poults in a flock affected with a derangement of the hock joint which caused the foot to turn outward and in which the mortality did not exceed 10 percent were demonstrated by the Kentucky Experiment Station to be members of the Senftenberg type of *Salmonella*. This is said to constitute the first recognition of the Senftenberg type in animal disease.

AGRICULTURAL ENGINEERING

[Agricultural engineering investigations by the Illinois Station] (*Illinois Sta. Rpt. 1935*, pp. 126, 127, 220-240, figs. 2).—The progress results are briefly reported of investigations by E. T. Robbins and C. W. Crawford on factors affecting the pulling power of horses and mules; use of electricity in agriculture, by E. W. Lehmann and A. L. Young; farm sewage disposal, by Lehmann and A. M. Buswell; tractor lubrication, by R. I. Shawl; trash covering equipment for plows, by Young, Shawl, and T. Cleaver; soil erosion control, by Lehmann and R. C. Hay; combine harvesting, by Lehmann, Young, and Shawl; harvesting and storage of artichokes, by Lehmann and Shawl; artificial drying of corn, by Lehmann, R. H. Reed, W. L. Burlison, and G. H. Dungan; stationary spraying, by Lehmann, Reed, H. W. Anderson, and R. L. McMunn; apple washing, by Reed; and gas production from farm wastes, by Buswell, Lehmann, and E. E. De Turk.

[Agricultural engineering investigations by the Indiana Station] (*Indiana Sta. Rpt. 1936*, pp. 8-16, figs. 6).—The progress results are briefly reported of investigations on electric fences, electric heaters for fruit washers, use of electric energy in brooding chicks, power consumption of portable and stationary spray plants, electric dairy water heaters, soil heating with electric energy, storage of sweetpotatoes, precooling cantaloups and peaches in refrigerator cars, cornstalk covering equipment, mechanical corn production, mechanical corn picker loss, Canada thistle-control equipment, rubber tires v. steel wheels for tractors, combined harvester-threshers, combining oats, air-cooled apple storages, low-pressure pneumatic tires for manure spreaders, poultry housing, hay and grain drying, and soil conservation.

Measuring equipment used in watershed and hydrologic studies, W. D. ELLISON (*Agr. Engin.*, 18 (1937), No. 3, pp. 107-110, figs. 5).—In a brief contribution from the U. S. D. A. Soil Conservation Service this equipment is described.

Bibliography on land drainage, compiled by D. W. GRAF (*U. S. Dept. Agr., Bur. Agr. Engin.*, 1936, pp. [1]+245).—This mimeographed bibliography contains an author index in addition to the list of publications.

Notes on soil mechanics and foundations, F. L. PLUMMER (*Ann Arbor, Mich.: Edwards Bros.*, 1936, pp. VII+139, figs. 129).—This publication summarizes available information on soil dynamics as related to foundations. It contains chapters on the geology of soils; soil properties and soil tests; colloids; mechanical analysis; soil moisture and limits of consistency; subgrade soil classification; permeability; shearing strength, cohesion, and internal friction; compressibility and consolidation; frost action; stress distribution; bearing capacity of soils and piles; settlement of structures; stability of slopes; soil pressure against retaining walls; and soil compaction and proctor tests.

Proceedings of the International Conference on Soil Mechanics and Foundation Engineering, June 22 to 26, 1936 (Cambridge, Mass.: Harvard Univ., 1936, vol. 3, pp. VIII+268+[1]+18, figs. [380]).—Papers of significance to agricultural soil dynamics are included on Pressure Distribution, by F. Kögler (pp. 66-70); Discussion on the Distribution of Stress Around a Pile, by R. D. Mindlin (p. 71); A Graphical Method for Determining the Distribution of Stress in the Underground Due to Foundation Loads, by D. M. Burmister (pp. 71-73); A Method for Determining the Shearing Resistance of Fill Materials, Earth Embankments, etc., in Place by Means of a New Shear Apparatus, by D. M. Burmister (pp. 114-116); Discussion on Gilboy's Presentation of Jürgenson's Method of Foundation Analysis, by T. A. Middlebrooks (p. 118); Notes on the Stability of Slopes, by D. W. Taylor (pp. 118-122); Two Examples Concerning Underground Sliding Caused by Construction of Embankments and Static Investigations of the Effectiveness of Measures Provided to Assure Their Stability, by E. von Gottstein (pp. 122-128); Discussion on the Lateral Resistance of Piles, Paper No. H-1, by P. Raes and A. E. Cummings (pp. 138-140); Pressure Distributions on Retaining Walls, by R. D. Mindlin (pp. 155, 156); Direct Measurement of the Permeability of the Ground, by J. P. Daxelhofer (pp. 164, 165); and Comparative Studies of the Effectiveness of Different Methods for Compacting Cohesionless Soils, by W. Loos (pp. 174-179).

Mechanics of materials, S. G. GEORGE and E. W. REITGER (*New York and London: McGraw-Hill Book Co.*, 1935, pp. XII+483, figs. 428).—This text covers the essential topics of a first course in mechanics of materials. It contains chapters on stress and strain; testing materials; tension and compression; riveted joints; torsion; simple beams, shear, and moment; stress in beams; elastic curve; stress intensities on different planes; columns; nonprismatic and special beams; and slope and deflection, moment area method, theorem of three moments.

The effects of service on automobile crankcase oils, J. I. CLOWER and N. W. CONNER (*Va. Engin. Expt. Sta. Bul.* 28 (1937), pp. 40, figs. 14).—Studies are reported which indicate that all of the changes which an oil in a crankcase undergoes are not deleterious and some are beneficial. For example, film breakdown and viscosity index tend to improve with use. Other properties, such as carbon residue, neutralization number, ash and iron content, hemacytometer count, and precipitation number show a decided tendency to increase, while viscosity, surface tension, dilution, and pour point follow no definite trend but vary widely with operating conditions.

It appears that the importance of the properties of new oils, as measured by laboratory tests, has been overemphasized, because oils in service only retain their original properties for a comparatively short period of time. Consequently the major problem is not one of selection but rather one of maintaining the oil in the desired condition.

An extensive bibliography is included.

Farm enterprise mechanics, G. A. SCHMIDT, G. F. HENBY, M. HENDERSON, F. J. ZINK, J. D. LONG, L. R. LARSON, R. H. SMITH, E. R. BRISTOL, H. O. SAMPSON, and F. C. LEWIS, edited by K. C. DAVIS (*Chicago: J. B. Lippincott Co., 1935, pp. [IX]+408, [figs. 60?]*).—This is a practical treatise on construction, care, and repair of farm equipment.

The farmer's shop book, L. M. ROEHL (*Milwaukee: Bruce Pub. Co., [1936, 5. ed.], enl. and rev., pp. 471, [pl. 1], figs. 247*).—This is an enlarged revised edition of this practical treatise (E. S. R., 56, p. 283).

Farm machinery and equipment, H. P. SMITH (*New York and London: McGraw-Hill Book Co., 1937, 2. ed., pp. XIII+460, figs. 700*).—This is the second edition of this book (E. S. R., 62, p. 382), in which the greater portion of the text has been revised and rewritten to take full account of the many developments in farm machinery during the past 7 yr., particularly in tractor-drawn implements. New chapters have been added, discussing farm machinery in its relation to agriculture, dusting and spraying equipment, and terracing machinery. The chapters on wagons and motor trucks have been combined and supplemented with a treatment of the automobile trailer. Many of the illustrations have been replaced by either new or improved ones, to show the latest types of machines now available.

The discussion of the developments on the mechanical harvesting of cotton has been brought up to date, giving results of experimental work done during the past few years, especially at the Texas Experiment Station. Improvements in haying machinery, such as placing the gears in a bath of oil enclosed in a dust-proof case and the windrow pick-up baler, are described and illustrated. A number of illustrations show machinery equipped with rubber tires, an innovation on many farm implements. In general, an effort has been made to bring the entire subject matter of the text up to date and to show the latest developments in the field of farm machinery.

Studies in power farming (*Oxford: Univ. Oxford, Agr. Econ. Res. Inst., 1936, pp. 77, figs. 2*).—This contains two studies.

Part 1, **Mechanized Corn-Growing**, by A. Bridges and H. Whitby (pp. 7-48), deals with the organization of a number of large mechanized grain-growing farms, which were the subject of a survey made in the autumn of 1934. As a survey of the same farms, and some additional farms which properly come within the definition of mechanized grain-growing farms, is now being repeated, this report is in the nature of a preliminary statement, confined mainly to an account of the facts relating to the organization for production of the farms in question. The report is concerned with 28 English farms where the combine harvester-thresher was in use during the grain harvest of 1934.

In part 2, **The Cost of Tractor Work**, by J. R. Lee (pp. 49-77), an economic analysis of the situation is presented.

Utilization of tractors and cost of tractor power on grain farms (northern Great Plains and Pacific Northwest, 1933), R. S. WASHBURN and R. S. KIFFER (*U. S. Dept. Agr., Bur. Agr. Econ., 1936, pp. [21]+51, fig. 1*).—The purpose of this mimeographed report is to show the extent to which tractors are used for farm power, the type and size of tractors in use, the kinds of work done, and the cost of using tractors on representative farms in the grain-producing

sections of the northern Great Plains and of the Pacific Northwest. The study was made in April, May, and June, 1934, and for the most part applies to the crop year 1933. The field data were obtained by personal interviews with 1,674 farm operators.

It was found that for the ordinary high-wheel tractor in the northern Great Plains, fuel and lubricants constituted 44.3 percent of the total annual cost of operating tractors, cash repairs 10.4, hired labor on repairs 0.1, other labor 1.7, depreciation 33.3, and interest 10.2 percent. In the Pacific Northwest, the percentage distribution of the total cost for track-laying tractors was as follows: Fuel and lubricants 47.3 percent, cash repairs 11.1, hired labor 0.3, other labor 1.5, depreciation 30.4, and interest 9.4 percent.

In the northern Great Plains the work of general-purpose tractors amounted to an average of 458 hr. per tractor per year, for ordinary high-wheel tractors 392 hr., and for track-laying tractors 760 hr. The greater annual use of the general-purpose tractor as compared with the ordinary high-wheel tractor was mainly accounted for by its use in cultivating row crops. The large number of days of annual use of the track-laying tractor was mainly because of the fact that this type of tractor was used almost exclusively on farms of the largest crop acreages. In the Pacific Northwest the work of ordinary high-wheel tractors and of track-laying tractors amounted to an average of 373 and 657 hr. per tractor per year, respectively. As in the northern Great Plains, the lesser amount of work done annually with high-wheel tractors than with track-laying tractors was largely because of the fact that the high-wheel tractor was used principally on the small- to medium-sized farms.

The distribution of tractors of different types and sizes in the northern Great Plains by hours used annually shows that 71 percent were used 500 hr. or less and 19 percent from 501 to 750 hr., whereas only 10 percent were used over 750 hr. In the Pacific Northwest 53 percent of the high-wheel tractors were used 400 hr. or less, 37 percent from 401 to 800 hr., and only 5 percent more than 800 hr. annually. Thirty-one percent of the track-laying tractors were used 400 hr. or less, 43 percent from 401 to 800 hr., and 26 percent more than 800 hr. annually.

Utilization of combined harvester-threshers and cost of harvesting small grains with a combine (northern Great Plains and Pacific Northwest, 1933), R. S. WASHBURN (*U. S. Dept. Agr., Bur. Agr. Econ., 1936, pp. [2] + 29, fig. 1*).—The purpose of this mimeographed report is to show the extent to which combines are used, the size of combines, the kinds of grains harvested, and what present owners and prospective purchasers of combined harvester-threshers can reasonably expect in the way of costs of using combines in grain-producing areas of the northern Great Plains and of the Pacific Northwest. The study was made in April, May, and June, 1934, and for the most part applies to the crop year 1933. The field data were obtained by personal interviews with 1,674 farm operators.

The data show that combines in the northern Great Plains were used an average of 152 hr. annually, of which 146 were for home work and 6 were for custom work. The work of combines in all areas was principally that of harvesting and threshing wheat. Combines in the Pacific Northwest were used an average of 186 hr. annually, of which 172 were for home work and 14 were for custom work. The work of combines in these areas was almost entirely that of harvesting and threshing wheat. Of an average of 515 acres of grain cut per combine per year for combines of all sizes, 474 acres were cut on the home farm, of which 456 acres were wheat.

In the northern Great Plains, 63 percent of the 12-ft. combines cut 400 or fewer acres annually, whereas 61 percent of the 16-ft. combines cut over 400 acres annually. For combines of all sizes, 37 percent cut 300 or fewer acres, 46 percent cut from 301 to 700 acres, and 17 percent cut over 700 acres annually. In the Pacific Northwest, 75 percent of the 12-ft. combines cut 400 or less acres annually, whereas 69 percent of the 16-ft. machines cut over 400 acres annually. For all combines represented, 29 percent cut 300 or fewer acres, 54 percent cut from 301 to 800 acres, and only 17 percent cut over 800 acres annually.

For the northern Great Plains, fuel and lubricants constituted 15.1 percent; cash repairs, 15.9; owner and family labor on repairs, 2.0; hired labor, 0.4; depreciation, 51.6; and interest, 15.0 percent of the total annual cost of operating combines. For the Pacific Northwest, the percentage distribution was fuel and lubricants, 14.3 percent; cash repairs, 24.0; owner and family labor, 2.9; hired labor, 1.2; depreciation, 41.4; and interest, 16.2 percent.

Effect of tractor tire size on drawbar pull and travel reduction, L. W. HURLBUT and C. W. SMITH (*Agr. Engin.*, 18 (1937), No. 2, pp. 53-57, figs. 23).—Further studies conducted at the Nebraska Experiment Station are reported (*E. S. R.*, 75, p. 406), using footings of fine sand and wild hay meadow stubble on a loamy fine sand. The equipment used in making the test was the same as used the preceding year and consisted of five sizes of pneumatic tractor tires, as follows: 9.00×24, 9.00×36, 11.25×24, 12.75×24, and 13.50×24, and a set of steel wheels and lugs. A Douglas truck was the foundation of the drawbar loading unit. The object of the tests was to get more information on the effect of tire cross section on the drawbar pull of a tractor, and the rear weight of the tractor was kept constant at 2,780 lb. Third gear was used for all tests.

A group of charts is presented comparing the drawbar pull of each tire when carrying 8 lb. and 16 lb. of air pressure, for both the cornfield and the hay stubble. The 8-lb. inflation pressure gave the greater traction for both footings and for all tires.

Another group of charts is presented comparing all tires in drawbar pull, first at 8-lb. inflation pressure and then at 16-lb., both for the field and stubble. A curve for steel wheels was plotted with the rubber tire data, and for the cornfield the steel wheel was better than rubber with 16-lb. inflation pressure but not so good as the rubber with 8-lb. pressure.

The 9.00×36 tire stood out as the best under most circumstances. No great difference could be observed in the tractive ability of the others. Once the load became too heavy to be pulled in the sand, the tires with the smaller cross sections would tend to dig in and bury themselves much more rapidly than those with larger cross sections.

A third set of charts compared the delivered horsepower of all tires, first using 8-lb., then 16-lb. inflation pressure. The tires giving the largest effective wheel diameters gave the greatest horsepower. With the drawbar pull approximately the same, the horsepower varied as the rate of travel. The drawbar pull with 16-lb. inflation pressure was so much below that for 8-lb. that the delivered horsepower at 8-lb. exceeded that at 16-lb. definitely.

Two charts compared the drawbar pulls with tire cross section. In the chart for the cornfield there seemed to be a slight tendency for a small increase in drawbar pull with tire cross section, but in the chart for the hay stubble the curves indicate no difference in traction due to tire cross section.

Two charts comparing the effective wheel diameters with drawbar pulls showed a slight advantage for the larger diameter tires. The hay stubble proved to be the best traction surface thus far encountered.

Tillage, planting, and harvesting equipment on grain farms and rates of doing field work with these implements when drawn with horse and with tractor power (northern Great Plains and Pacific Northwest), R. S. WASHBURN and D. MERRICK (*U. S. Dept. Agr., Bur. Agr. Econ., 1936, pp. [2]+51, fig. 1*).—This mimeographed report presents information relative to kind, size, and accomplishment of field implements on representative grain farms. The first part of the report gives numbers and sizes of field implements by type-of-farming areas. The second part shows the rates at which these implements did field work when drawn with horses and with tractors. The study was made in April, May, and June, 1934, and for the most part applies to the crop year 1933. The field data were obtained by personal interviews with 1,674 farm operators in grain-producing areas of the northern Great Plains and the Pacific Northwest.

Tests of tillage tools.—I, Equipment and procedure for moldboard plows, I. F. REED (*Agr. Engin., 18 (1937), No. 3, pp. 111–115, figs. 11*).—Methods, equipment, and studies being conducted at the Alabama Experiment Station in cooperation with the U. S. D. A. Bureau of Agricultural Engineering are described.

Load studies on tillage tools, A. W. CLYDE (*Agr. Engin., 18 (1937), No. 3, pp. 117–121, figs. 9*).—Studies continued at the Pennsylvania Experiment Station (E. S. R., 74, p. 706) are reported. Tools studied included moldboard plows of speed type and of conventional shape at 2.5 and 4.5 m. p. h.; moldboard plows with rolling colter, and combined colter and jointer, in moist and dry sod; moldboard plow with U. S. D. A. self-aligning disk jointer, in moist and dry sod; disk plow, 24 in.; and disk harrow, 18 in.

It was found that the useful soil force on plows and disks is usually made up of nonconcurrent parts. They can be combined into two nonconcurrent forces, or into a resultant force and a couple, as desired. Information as to particular tools under certain conditions is given. The speed-type moldboard plow required less draft at both 2.5 and 4.5 m. p. h. than the one of conventional shape. At the higher speed the speed-type bottom did a better job of covering.

The U. S. D. A. self-aligning disk jointer in heavy plowing gave a substantial reduction in total draft, but an increase in side force, as compared with colter and jointer equipment. In 7-in. plowing with the disk set 2 in. over the point, the disk used over 40 percent of the draft, leaving less than 60 percent for the plow. The self-aligning feature protected it from damage by stones.

Examples are given of using soil force measurements for computing bearing loads on the disk jointer and disk plow. Wide spacing of bearings reduces the loads because of the overhanging nature of the forces. The conclusion is drawn that the commonly used center-of-resistance rule for plow hitches is wrong, because it takes no account of the weight of the tool nor of varying soil forces. Suggestions are given for a rule which will be of more universal application.

The small combine harvester thresher, E. C. SAUVE (*Michigan Sta. Quart. Bul., 19 (1937), No. 3, pp. 162–164, fig. 1*).—The results of the survey of the use of the combine harvester-thresher by Michigan farmers are briefly presented, indicating that 5- or 6-ft. combines, reasonably priced, will give satisfaction and economy.

Electric soil heating for hotbeds, T. E. HENTON and J. H. MACGILLIVRAY (*Indiana Sta. Circ. 226 (1936), pp. 16, figs. 9*).—The results of studies are briefly reported which showed that the use of soil-heating cable for heating hotbeds

electrically is superior to the individual heater from the standpoint of ease and cost of installation and cost of operation. Cabbage and tomato plants will germinate in less time and the plants grow faster in hotbeds with the cable installed on the surface of the soil, or in the soil and air, or at a depth of 3 in. in the soil than in those where the cable is 6 in. below the soil surface. Records of 35 electrical hotbeds operated in the State from 1931 to 1936 showed a variation in consumption from 0.22 to 3.6 kw.-hr. per 3- by 6-ft. sash per day. Of the entire group, 8 used less than 1 kw.-hr. per sash per day, 12 used from 1 to 1.5, 7 used from 1.5 to 2, 4 used from 2 to 3, and 4 used more than 3 kw.-hr. Covering hotbeds at night reduced the amount of energy consumed, and the use of cinder insulation under and around the beds showed a saving of 20 percent in amount of electricity used. Banking the frames with soil and fitting sash tightly to the frames likewise reduced energy consumption. Control of heating units with thermostats showed no advantage in saving of electric energy over manual control, but eliminated the necessity for close personal attention to temperature regulation.

Electrification of a fruit farm, T. E. HENTON (*Agr. Engin.*, 18 (1937), No. 2, pp. 68-70, figs. 4).—In a brief contribution from the Indiana Experiment Station uses of electricity for operating water pumps, spray plants, fruit washers, fruit sizers, cider presses, and fans and refrigerators in fruit storages and for other purposes are described.

Losses of organic substance in the spontaneous heating of alfalfa hay, E. J. HOFFMAN and M. A. BRADSHAW (*Jour. Agr. Res. [U. S.]*, 54 (1937), No. 3, pp. 159-184).—In a series of 7 large-scale storage experiments conducted by the U. S. D. A. Bureau of Chemistry and Soils, of which 6 were with alfalfa hay and 1 with clover, the extent of the losses of the organic substance of hay resulting from spontaneous heating was determined, and in 4 of these the nature of the losses was investigated. The length of storage in these experiments ranged from 1 to 7.5 mo. The samples of hay investigated contained moisture ranging from approximately 28 to 70 percent. The moisture content of the hay immediately surrounding the samples in the mows was between the limits of approximately 10 and 60 percent, while the average moisture content of the mows ranged from 18 to 35 percent.

The greatest losses in organic substance as determined by loss in weight occurred in those experiments in which hay of very high moisture content was stored in a mow whose average moisture was also high. In these experiments the maximum loss was approximately 22 percent, the minimum 4, and the average nearly 13 percent. Losses in the individual samples varied with the respective conditions and surroundings in which these were located in the mows, particularly with respect to the free passage of air.

The losses in organic substance were much less when the hay samples approximated normally cured hay in moisture content and were stored in a mow of much lower moisture content. Here the maximum loss was 8 percent and the average about 6 percent. When a relatively small proportion of the mow was of high moisture content while the remainder was very dry, the losses were also comparatively small for samples of high moisture content, the maximum loss being 8.6 percent and the average loss less than 3.5 percent.

The greatest losses of organic substance occurred in experiments in which the moisture conditions were favorable to heat production and in which the highest temperatures were recorded.

The results of the investigation demonstrate the seriousness of the losses in the value of hay resulting from the spontaneous heating of undercured hay. They show further that loss in weight alone of organic substance does not indi-

cate fully the extent of loss in value, as evidenced by the fact that most of the undercured hay of those mows in which the maximum loss was 22 percent had deteriorated into hay of very inferior quality.

The one experiment designed to show the effect of salting upon spontaneous heating failed to show any material difference in hay substance loss due to the use of approximately 1.5 percent of salt.

Investigation showed that the losses of organic substance incurred under these storage conditions involved definitely and chiefly the fats, the sugars, and the hemicellulose group. Where the extent of losses was greatest, cellulose and crude protein also had been attacked. Lignin apparently suffered no loss.

Treatment of milk wastes: American and European practice, A. M. BUSWELL (*Milk Plant Mo.*, 26 (1937), No. 1, pp. 28-30, fig. 1).—This contribution from the University of Illinois presents a technical discussion of the treatment of milk wastes.

AGRICULTURAL ECONOMICS

[Investigations in agricultural economics by the Illinois Station, 1934-35] (*Illinois Sta. Rpt. 1935*, pp. 183-219, figs. 4).—Results of investigations not previously noted are reported as follows: Tables by H. C. M. Case, M. L. Mosher, J. B. Andrews, J. B. Cunningham, and W. A. Herrington showing the variations in earnings and the causes therefor on farms in 8 counties; tables by P. E. Johnston, Case, Andrews, E. L. Sauer, and T. R. Hedges showing averages by counties or groups of counties for capital investment, receipts, expenses, etc., in 1934 on 1,548 farms; findings in the survey in 1934 by Case and G. L. Jordan of the long-time and production credit used by 77 farm operators; tables by R. C. Ross, Case, Sauer, and E. B. Colegrove showing the yields and net costs per bushel and net profit per acre of different crops, costs and profits for different kinds of livestock, and costs of horse and tractor power on 'Champaign and Piatt County farms in 1932, 1933, and 1934; a table by Johnston and J. E. Wills showing the average costs, 1930-33, for man labor, horse work, and machinery on 5,220 central Illinois farms grouped by number of crop acres per farm; findings by C. L. Stewart in studies of farm real estate, taxes and tax delinquency, land values, land transfers, and the relation between tenancy and land values; tables by Case, Sauer, and L. E. Card showing the average investment, receipts, expenses, and earnings of poultry enterprises on 37 farms and the cost of producing pullets to laying age in 1934, and the 12 most profitable and 12 least profitable farms; findings as to yields, costs, and net income in 1934 on 25 fruit and 8 vegetable farms, studied by Johnston and V. W. Kelley; findings in a study by J. W. Lloyd as to possible ways of reducing costs in peach packing, and by Lloyd and S. W. Decker as to the reduction of deterioration of peaches by proper refrigeration; and findings by Jordan of the effects on soybean prices in Illinois of the United States production, weekly earnings of New York factory workers, and corn production in the United States.

[Investigations in farm management by the Indiana Station] (*Indiana Sta. Rpt. 1936*, pp. 41-44, figs. 2).—Brief summarizations are included of studies on pasture uses in southern Indiana; profitable farm practices; small combine harvester-thresher; farm machinery and farm power costs; adequacy of farm buildings; costs and practices with tomatoes, onions, and other intensive crops; relationship of farm tenure to profitable farming; part-time farming; basic information for agricultural adjustments; and patronage relationships of local grain elevators.

[Papers on agricultural economics] (*Sci. Agr.*, 17 (1936), No. 2, pp. 74-85, 92-97, 100-103).—Included are the following: Beef Cattle Production—a Problem, by G. B. Rothwell (pp. 74-82); The Horse Breeding Situation in Canada, by J. A. Ste. Marie (pp. 83-85); Marketing Legislation in New Zealand, by C. V. Parker (pp. 92-94); Objectives in the Alberta Land Utilization Survey, by G. H. Craig (pp. 94, 95); Some Data on the Consumption of Maple Products, by G. P. Boucher (pp. 96, 97); and Life Insurance Carried by Farmers in the Lomond and Vulcan Districts, Alberta, by W. J. Hansen and J. Proskie (pp. 100-103).

The recovery problem in the United States (*Washington, D. C.: Brookings Inst.*, 1936, pp. XIV+709, [pls. 5, figs. 62]).—Part 1, the sweep of world events, reviews the international setting of the depression in the United States in chapters covering the background, course, and world impact of the depression, and the extent and character of and government policies in relation to recovery. Part 2, readjustments in the United States, is a more detailed study of the course of the depression and recovery in the United States in chapters on employment and unemployment, production and productivity, accumulated needs in durable goods, reemployment possibilities, wage readjustments, changes in the price structure, the trend of government finance, readjustments of private debt, interest rates and the availability of credit, trends in international trade and financial relations, and changes in monetary relations. Part 3, readjustments required for recovery, includes chapters on the recovery program of the United States Government, government credit and general financial stability, international economic policies, and wage and price policies. Appendixes include statistics relative to world trends, brief summaries of legislation in 14 countries during the depression, data relating to employment, production, wages, durable goods, prices, public finance, private debts and interest payments, and international trade and finance.

Agrarian problems in southernmost China, CHEN HAN-SENG (*Shanghai: Kelly & Walsh*, 1936, pp. VIII+144).—This study "limits itself in the main to a presentation of the facts and attempts to give a rounded and realistic account of the most important elements in the problem situation without, on the one hand, tracing these all the way to their historical sources or, on the other, drawing all the conclusions about the nature and probable trends of their respective effects which it would be possible to deduct." The chapters deal with distribution of land ownership and use; the economic and political position of the collective landlords; the system of tenancy; the rent and price of land; taxes, tolls, and torts; trade and credit; and the decline of wages and the loss of labor power.

Supplementary report of the Land Planning Committee to the National Resources Board, I-X (*Washington: Gort.*, 1936, pt. 1, pp. V+47, figs. 37; 1935, pts. 2, pp. V+114, figs. 13; 3, pp. V+64, figs. 23. [maps 2]; 1936, pt. 4, pp. V+51, figs. 2, [maps 2]; 1935, pts. 5, pp. V+112, [pls. 5], figs. [18], [map 1]; 6, pp. V+55, figs. 7, [map 1]; 7, pp. V+139, [pl. 1], figs. [9]; 8, pp. VII+114, [pls. 4], figs. 58; 9, pp. V+24, figs. 2; 10, pp. V+73, figs. 11).—The following are supplementary reports to that previously noted (E. S. R., 73, p. 403):

Part 1, general conditions and tendencies influencing the Nation's land requirements, deals with the outlook for population, basic industrial conditions, and the relation of mechanical progress in agriculture to land utilization and land policy. Part 2, agricultural exports in relation to land policy, deals with the general considerations relating to agricultural exports, international payments in relation to such exports, the probable development of population in foreign countries and its significance for agricultural exports, the prospective

world wheat situation in relation to American exports, and the prospective foreign demands for American cotton, tobacco, and fruit. Part 3, agricultural land requirements and resources, deals with the per capita consumption of farm products, yield factors in cropland requirements, prospective acreage requirements for crops and for pasture, trends in area and productivity of range lands and land available for range, prospective modification and trends in crop acreage harvested in the various regions of the United States, and classification of land relative to productivity. Part 4, land available for agriculture through reclamation, includes sections on the extent of land use under irrigation, relation of drainage to land use policies, and farm land available through clearing. Part 5, soil erosion—a critical problem in American agriculture—deals with the crisis in land utilization, the process and effects of soil erosion, national erosion reconnaissance, erosion conditions in the United States, erosion control demonstration on a national scale, a national policy of erosion control, the future of erosion control, erosion conditions by States, engineering aspects of erosion control, and farm organization and related facts for selected areas in erosive regions. Part 6, maladjustments in land use in the United States, deals with the desirable major land use adjustments and their regional distribution, conditions of areas in which farm retirement is proposed, the program for retirement of poor farm land, drought frequency, and rural-urban migration in relation to land quality. Part 7, certain aspects of land problems and Government land policies, includes sections on the problems of range lands, farm tenancy in the United States, a program for chronically tax delinquent and tax reverted land, policies with reference to adjustments in local government and finance, recent land policies of the Federal Government, a summary of the status of Federal and State lands, development of a unified land program, land use planning and production control, public policies for facilitating land settlement, and other measures for discouraging settlement on poor lands. Part 8, forest land resources, requirements, problems, and policy, deals with the general concepts of requirements of forests and forest products, a study of timber consumption and requirements, forest land area and its management in relation to the Nation's requirements, other values of forests, land available for forests, progress in forestry and major problems, present and recommended ownership of forest land, areas that should continue in private ownership, measures needed to safeguard the public interest in private forests and to aid private forestry, areas recommended for ultimate public ownership, administration and development of public forest holdings, program for the protection of public and private forest lands, Federal and State aid for protection and development, and forest research and extension. Part 9, planning for wildlife in the United States, covers sections on the requirements for wildlife areas, policies with respect to wildlife, and wildlife management in national forests. Part 10, Indian land tenure, economic status, and population trends, includes sections on the complexities of Indian land tenure arising from the allotment system, social and economic survey of selected Indian reservations, agricultural credit needs of the Indians, and the trend of Indian population.

State planning; A review of activities and progress, National Resources Board, June 1935 (*Washington: Govt., 1935, pp. XIII+310, [figs. 117]*).—This publication of the National Resources Board is a review of the activities and progress of State planning boards.

Research program in relation to economic planning for agriculture, C. O. BRANNEN (*Southwest. Social Sci. Quart., 17 (1936), No. 3, pp. 281-289*).—This is a brief discussion of the method of approach in a research program and the information needed in economic planning for agriculture.

First report on State policies, S. R. DE BOER (*Salt Lake City: Utah State Planning Bd., 1935, pp. [13]+159+[6]*).—This first report of the Utah State Planning Board includes an outline of the principles and procedure adopted by the board and the following reports: Policy planning for Utah, land use policies, water resources policies, mineral resources policies, power resources policies, scenic resources policies, and population policies.

Planning and political geography, W. H. MILLER (*Jour. Land and Pub. Util. Econ., 12 (1936), No. 4, pp. 422-426, fig. 1*).—Six general guiding principles are set out for the division of a State into counties, and suggested plans for dividing California into 5 and 14 counties are discussed briefly.

Geography and the relief problem in Texas and Oklahoma, M. F. BURRILL (*Southwest. Social Sci. Quart., 17 (1936), No. 3, pp. 294-302*).—This is a brief discussion of the relation of the geography of these States to the relief program.

Iowa income, 1909-1934 (*Iowa City: State Univ. Iowa, Bur. Business Res., 1935, pp. 122, [figs.] 22*).—"This study of Iowa income was undertaken and carried to completion under the auspices of the population and social trends committee of the Iowa State Planning Board. Its primary objectives, as a planning project, were (1) to determine the amount and the trend of income available to the people of the State, to provide a basis for estimating economic welfare and progress; (2) to analyze the composition of the State's economic structure by showing the relative importance of the various industries; and (3) to indicate the direction in which the economic life of the State is moving."

The income of the counties of Iowa ([*Ames*]: *Iowa State Planning Bd., [1935], pp. [2]+32, [pls. 4]*).—This bulletin supplements that noted above. Tables and maps show by counties the average, total, and per capita incomes for the periods 1927-29 and 1931-33 from different industries, and the percentage distribution between counties of the total income from each industry.

A series of industrial studies for Utah, 1935, D. C. HOUSTON and R. M. HILL (*Salt Lake City: Utah State Planning Bd., 1936, pp. [8]+106+[2], figs. 24*).—Included are reports on employment, wealth, and income in Utah; the decline of Utah's manufacturing industries; agricultural cooperation in Utah; Utah's important out-of-State markets for products of agriculture; cooperative marketing among Utah poultrymen; Utah's dairy industry; marketing methods and practices among Utah honey producers; commercial traffic by automotive truck through Santa Clara; and miscellaneous studies.

Township organization in Missouri, W. L. BRADSHAW and M. GARRISON (*Missouri Univ. Studies, 11 (1936), No. 4, pp. 70, fig. 1*).—This study deals principally with the optional system of township government existing in 24 counties of the State. It includes chapters on the history of townships in Missouri, nature of township organization, taxation and financial administration, and township roads and bridges.

Agricultural labor problems in Arkansas (*Ark. State Policy Com., Pub. Paper No. 1 (1936), pp. [3]+34, figs. 4*).—This is a report on farm tenancy in Arkansas prepared by a subcommittee of the Arkansas State Policy Committee.

A report on the rehabilitation of the dry areas of Alberta and crop insurance, 1935-1936 (*Edmonton, Alta.: Min. Agr., 1936, pp. 80, figs. [6]*).—This is a report of the committee appointed by the Minister of Agriculture to investigate and report upon the problems in the drought area of Alberta, including the causes and methods of control of soil drifting, farm management practices and livestock policy, conservation of feed and water supplies, educational and demonstrational programs, and crop insurance.

The mechanisation of agriculture in Latvia, V. KUNKIS ([*Internatl. Rev. Agr.*], *Mo. Bul. Agr. Econ. and Sociol.* [Roma], 27 (1936), No. 9, pp. 293-306).—Mechanization as a fundamental problem of the agriculture of Latvia and the Government measures to encourage it are discussed.

Land settlement: A report prepared for the Carnegie United Kingdom Trustees, A. W. MENZIES-KITCHIN (Edinburgh: T. & A. Constable, 1935, pp. XVI+175, [pls. 2, fig. 1]).—This report is based upon studies of inquiries in Great Britain and data collected in Germany, Denmark, and the Netherlands, and was made from the standpoint of land settlement as a social problem rather than as a relief for unemployment. The several chapters deal with general and economic conditions, legislation in Great Britain, Germany, Denmark, and the Netherlands, small holdings and the economics thereof, vegetable, pig, and poultry production, the organization of land settlement, and subsistence holdings in Great Britain, Germany, and the United States.

Report on the work of the Land Division of the Ministry [Great Britain] for the year 1935, D. B. TOYE ([*Gt. Brit.*] *Min. Agr. and Fisheries, Land Div. Rpt.*, 1935, pp. IV+65).—The work of the division under the several acts administered by it is summarized.

Land settlement in Germany, C. TURNOR (London: P. S. King & Son, 1935, pp. 30, [pl. 1, figs. 6]).—The types of settlement and operation of the settlement system in Germany are described and compared with those in England.

Changes in farms and farm tenure, 1930-1935, G. S. WEHRWEIN (*Jour. Land and Pub. Util. Econ.*, 12 (1936), No. 2, pp. 200-205, fig. 1).—A map shows by States the percentages of tenancy in 1930 and 1935. The changes are discussed, and a table is included showing for 1925, 1930, and 1935 the number of States in which the number of farms, owner farms, and tenant farms all increased or decreased, and the number of owner farms and the number of tenant farms which increased or decreased when the other type of farms or all farms increased or decreased.

Farm organization and soil management practices in four Ohio areas, F. L. MORISON and J. I. FALCONER (*Ohio State Univ., Dept. Rural Econ. Mimeogr. Bul.* 97 (1937), pp. [1]+17).—Included are preliminary data released for use in a county agricultural planning project conducted in cooperation with the U. S. D. A. Bureau of Agricultural Economics and Soil Conservation Service. Tables show for the period 1933-36 for each of 4 areas, including 86 farms in Ashtabula County, 80 in Wyandot County, 76 in Wood County, and 33 River Valley farms in Pike County—areas typical of larger sections in their respective parts of the State—the crop yield index, percentages of rotated area in different crops, percentages of hay acreage in different hays, amounts of fertilizer and lime used per 100 rotated acres, tenure and size of farms, yields of chief crops, animal units per farm and per 100 rotated acres, and labor income, 1935, per farm and per rotated acre. In making the analysis the farms are divided into 5 groups each on the basis of annual soil productivity and crop index (except Pike County). Groupings on the basis of size of farm were also made in Wyandot and Wood Counties and in number of rotated acres in Pike County.

A survey of small farming in Hawaii, F. E. ARMSTRONG (*Hawaii Univ., Res. Pubs.* No. 14 (1937), pp. 90).—Some of the characteristics of the farms and their operators; the tools, equipment, and conveniences; livestock, field crop, fruit, nut, and vegetable production on such farms; and the income and supplementary occupations of the operators are discussed.

The social income and family farm earnings of farm from 1927-28 to 1931-32, J. DESLARZES ([*Internatl. Rev. Agr.*], *Mo. Bul. Agr. Econ. and Sociol.* [Roma], 27 (1936), No. 4, pp. 122-133).—A table is included showing, by general averages for 1927-30, 1930-31, and 1931-32, and for 1931-32 by farms grouped

by size, area, or type of enterprise, the income passing to third parties (taxes, interest, and wages) and returns to operators in Denmark, Switzerland, Austria, Latvia, Estonia, Lithuania, Poland, Norway, Finland, Sweden, Germany, the Netherlands, etc.

Social income of farms in three States of the United States of America (Illinois, Iowa, Indiana) in 1932-33, J. DESLARZES ([*Internat. Rev. Agr.*], *Mo. Bul. Agr. Econ. and Sociol.* [Roma], 27 (1936), No. 7, pp. 203-216).—This is a study similar to that previously noted.

The home production of food supplies (Tennessee Sta. Rpt. 1936, pp. 4-6).—Results of the first season's work on a resettlement project near Crossville, on the Cumberland Plateau, are briefly noted.

Home-grown farm produce used by the farm household, E. B. HILL (*Michigan Sta. Quart. Bul.*, 19 (1937), No. 3, pp. 165-168).—Records were obtained for 1935 from 113 farms in southern Michigan, 41 in northern Michigan, and 9 in the Upper Peninsula. Tables show for each group of farms the average amounts and values of different products used in the home and the number of farms using each product. The average values of products used, excluding rent of house, were southern Michigan \$276 45, northern Michigan \$317.36, and Upper Peninsula \$286 22.

[Papers on marketing agricultural products] (*Jour. Marketing*, 1 (1936), Nos. 1, pp. 3-12, 35-39; 2, pp. 115-128, 143-149, fig. 1).—Articles on the marketing of farm products are included as follows: The Consumer and the Agricultural Adjustment Administration, by D. S. Anderson (pp. 3-9), with comments by E. A. Duddy (pp. 9-12); Market Research in Germany, by K. Brandt (pp. 35-39); Economic Provisions of Marketing Agreements for General Crops, by B. A. Holt (pp. 115-126), with comments by J. El. Boyle (pp. 127, 128); and Seasonal Storage [of Wheat] in China, by W. M. Stevens (pp. 143-149).

The Agricultural Marketing Acts, H. M. MONAGHER (*Edinburgh: W. Green & Son*, 1935, pp. VIII+192).—The texts of the Agricultural Marketing Acts of 1931 and 1933 of the British Parliament, the regulations under the legislation, and explanations and commentaries are included. Appendixes list the statutory rules and orders and the orders made by the Board of Trade, the Scottish and English milk marketing schemes, and the hops, pigs and bacon, and potato marketing schemes, and section 12 of the Milk Act of 1934.

Maize, G. H. FERGUSON ET AL. ([*Gt. Brit.*] *Imp. Econ. Com. Rpt.*, 28 (1934), pp. 60, fig. 1).—This report of the Imperial Economic Committee on the preparing for market and marketing of maize discusses the world production and trade, principal producing areas of the British Empire, the demand for maize and maize products in the United Kingdom and the Irish Free State, types and uses of maize in agriculture and manufacturing, marketing, wholesale prices, the possibilities of extending the market for Empire maize, and the outlook.

Marketing Michigan's tablestock rutabagas, B. R. CHURCHILL (*Michigan Sta. Quart. Bul.*, 19 (1937), No. 3, pp. 168-172, figs. 2).—The available markets, market demands, grading, and qualities preferred by producers are described.

Some statistical aspects of future trading on a commodity exchange, G. R. WHITE (*Jour. Roy. Statis. Soc.*, n. ser., 99 (1936), No. 2, pp. 297-342, pl. 1).—This is a study of the trading on the New York Hide Exchange from its beginning on June 4, 1929, through December 1935, to ascertain whether future trading has been of any benefit to the trade. "The analysis has shown (1) there is no evidence that the introduction of future trading in America has had any damping effect on hide price fluctuations, in fact, the evidence tends to point in the opposite direction, and (2) hedging has only provided imperfect price insurance, in some cases the operator making unexpected profits and in others

heavy losses." The investigations also showed that an alternative method of price insurance—an international insurance company—has possibilities that justify attention. Several short discussions follow the paper.

Cotton futures, H. BRAUN (*Das Baumcolltermingeschäft*, Stuttgart: C. D. Poeschel, 1936, pp. XI+224 [pls. 14, figs. 11]).—This is a study of the elimination of price risks by cotton futures in the cotton trade of North America, with special reference to the German cotton and ready-made goods industries.

Cooperative consumer credit, with special reference to credit unions, M. R. NEFFIELD (*New York and London: Harper & Bros., 1936, pp. X+223*).—The development, present status, and different types of credit unions are described. The strong and weak points of such unions are discussed, and a "27-point program" for such unions is presented. Appendixes include the uniform credit union law drafted by the Credit Union National Extension Bureau, the Federal Credit Union Act, a brief digest of State credit union laws, a suggested form for the annual report of credit unions, and a bibliography.

Co-operative insurance, N. BAROU (*London: P. S. King & Son, 1936, pp. XIII+391*).—"The object of this book is to outline the theory and practice of cooperative and mutual insurance throughout the world." The 12 chapters cover insurance (nature and elements), shortcomings of popular insurance, mutual insurance, cooperative insurance, consumers' cooperative insurance societies, cooperative labor insurance institutions, agricultural cooperative insurance (general societies) agricultural cooperative insurance (special societies), cooperative employees' insurance societies, organization, funds and their investment, and conclusions.

"Popular insurance, though of the greatest importance for the working population, is not covered sufficiently by social insurance and is not served satisfactorily by profit-making insurance companies. Because of this, wage earners and small farmers have been constrained to form their own insurance societies on nonprofit-making cooperative lines. The movement has been spreading rapidly during the last 70 yr., and it now comprises over 20 millions of members and has accumulated funds amounting to 1,000 million pounds. It must be made clear at the outset of this study that cooperative insurance can only supplement, but not replace or eliminate, social insurance. Present-day wages do not leave a sufficient margin for the wage earner to cover all his insurance needs, and the State must take care of a part of them."

Index numbers of prices and purchasing power of farm products in Norway, P. BORGEDAL (*Meld. Norges Landbr. Høiskole, 16 (1936), No. 7, pp. 531-546, fig. 1*).—Tables are included and discussed showing by months, April 1933-March 1936, the prices of different farm products and materials; the index numbers (1909-14=100) of grains, potatoes, hay, milk, meat animals, plant products, animal products, fertilizers, concentrates, building materials, machinery and equipment, freight rates, commodities bought for living and for use in production, and wages; and the purchasing power of farm products in commodities for production and living and wages, of milk, meat, pork, and eggs in concentrated feeds, and of plant, animal, and all farm products in fertilizers. Monthly indexes of the price of all farm products (1913-14=100) are also included.

International yearbook of forestry statistics, 1933-35.—I, Europe and U. S. S. R. (*Internat. Inst. Agr. [Roma], Internat. Yearbook Forestry Statis., 1933-35, vol. 1, pp. XII+327*).—Included are a summary and detailed tables relating to forests and the trade in lumber covering practically the whole of Europe and the Union of Soviet Socialist Republics.

RURAL SOCIOLOGY

A study of relief activities in seven Nebraska counties, 1927-1934. L. H. STORR (*Nebraska Sta. Res. Bul. 89 (1937), pp. 24*).—This investigation of the relief situation in Nebraska was undertaken (1) to determine how public relief funds were administered in the various counties of the State before the beginning of Federal participation, (2) to determine the amounts of goods distributed as part of the relief activities, and (3) to show the extent to which relief was extended to families actually engaged in farming. The data were obtained in two surveys, one in the spring of 1933 when information over a period of years was obtained and the other in the summer of 1934 covering the 6 mo. from July 1933 to January 1934. Information is presented for each of seven counties, together with a description of the type of farming and the general policy of relief administration during the period, with tabulated summaries of yearly expenditures of county funds for various relief purposes for 1927-33 and the relief activities of volunteer and Federal agencies in general for 1931-33. The extent of relief in relation to the character of the population for the various counties in 1932 and 1933 is shown in a summary giving the distribution of the population for each county and the total and per capita expenditures of county relief funds for the 2 yr.

General observations are given on the attitudes of county officials and relief workers.

Rural social welfare vitally affected by land usage. D. E. LINDSTROM (*Illinois Sta. Rpt. 1935, pp. 9-12, fig. 1*).—Studies conducted by the station, in cooperation with the National Resources Board, the Federal Emergency Relief Administration, the Illinois Planning Commission, and the Illinois Emergency Relief Administration, are briefly summarized.

Family life cycle analysis. C. P. LOOMIS and C. H. HAMILTON (*Social Forces, 15 (1936), No. 2, pp. 225-231, fig. 1*).—Using data obtained in a study of 1,144 rural families in Enfield Township, Halifax County, N. C., a test analysis is made using the historical and the cross-section methods. "The comparative analysis here presented, even though supported by an insufficient number of cases, leads the authors to the conclusion that the cross-section method is useful in the analysis of family living data. In certain areas where there have been no great changes in social and biological factors affecting the family, a relatively accurate picture of the historical life cycle of the farm family may be secured by the makeshift method—the cross-section analysis."

Youth.—VI, Community surveys. C. A. JESSEN and H. C. HUTCHINS (*U. S. Dept. Int., Off. Ed. Bul. 18 (1936), pt. 6, pp. X+97, pl. 1*).—Part 1 brings together the principal findings in 34 youth surveys in 18 States under the headings of education, employment, recreation, and subjects investigated less frequently. Part 2 analyzes and discusses the data obtained in 13 community surveys made by the Committee on Youth Problems of the U. S. Office of Education in sections on educational and employment findings and use of leisure time. Part 3 discusses the information to be gathered and the method of obtaining and analyzing such data.

Included is an annotated bibliography of the surveys considered in part 1 and the schedules used in the youth survey in the Office of Education.

AGRICULTURAL AND HOME ECONOMICS EDUCATION

Good 4-H work links with right farm attitudes. H. W. MUMFORD and D. E. LINDSTROM (*Illinois Sta. Rpt. 1935, pp. 8, 9*).—An analysis of the effectiveness of the 4-H club program as regards attitude toward farm life is briefly noted.

FOODS—HUMAN NUTRITION

Applied dietetics: The planning and teaching of normal and therapeutic diets. F. STERN (*Baltimore: Williams & Wilkins Co., 1936, pp. XXI+263, [figs. 11]*).—This book contains materials and data organized for use in the dietetic treatment of the ambulatory patient. The subject matter presents the principles of nutrition that are used as a basis in the planning of normal and therapeutic diets; the environmental conditions that may influence the effectiveness of the diet; methods and materials helpful in the education of the patient; tables and charts to simplify dietary computation; a series of dietary outlines illustrating that the therapeutic diet is a modification of the normal diet to compensate for changes in the body caused by disease or abnormal conditions; and typical diets and menus showing the foods necessary to supply the food constituents required for the normal diet and the variations in the therapeutic diets. The material was formulated in close association with the physician and should be helpful to the dietitian, social worker, nurse, public health worker, teacher, and student in home economics.

[**Food studies by the Illinois Station**] (*Illinois Sta. Rpt. 1935, pp. 294-300, fig. 1*).—This progress report (E. S. R., 74, p. 566) deals with a continuation of work under the direction of S. Woodruff on new methods of making starches from corn and the properties of the gels prepared from the various starches, a comparison of wheat starches with corn and potato starches, the bread- and cake-making qualities of different grades of flour from Fulho wheat, and the cooking quality and palatability of different varieties of soybeans of the vegetable type, both as green and as dry beans. Data are included on the proximate composition of four varieties of soybeans when green and when mature.

[**Studies in foods and nutrition of the Tennessee Station**], F. L. MacLEON (*Tennessee Sta. Rpt. 1936, pp. 43, 44*).—This progress report (E. S. R., 76, p. 125) includes data on the vitamin G content of canned green and white asparagus, dried leaves of *Lespedeza sericea*, green peas, green string beans, and sweet-potatoes, on the vitamin A content of the fresh and dried leaves of *L. sericea* and alfalfa, and on the utilization of dicalcium phosphate by the white rat.

[**Studies in foods and nutrition of the Washington Station**] (*Washington Sta. Bul. 342 (1936), pp. 40-42*).—Included in this progress report (E. S. R., 75, p. 136) are summaries of studies by E. N. Todhunter on varietal differences in the vitamin C content of apples (Golden Delicious, Rome Beauty, and Yellow Newtown) and of frozen red raspberries (Marlboro), on the relative vitamin C content of pared and unpared apples of the same varieties, and a comparison of heat-treated and alcohol-extracted casein as the source of protein in the basal vitamin A-deficient diet; by V. E. Sater on factors affecting the cost of operating domestic mechanical refrigerators, with special reference to different frozen dessert mixtures, and on time and cost evaluation of home canning; and by M. Boggs on time and cost evaluation of the home canning of beef-steak and chicken by different methods of preheating and in containers of different kinds and sizes.

Wheat: Pre-eminence as a cereal food; nutritive value; relation to health and disease (*Imp. Bur. Anim. Nutr. [Aberdeen], Tech. Commun. 7 (1936), pp. 31*).—In this communication the psychological and economic reasons for the overwhelming preference for wheat in the human dietary are considered. The nutritive value of wheat is compared with that of other common cereals. Communities living on an adequate diet containing milk, fruits, vegetables, and other protective foods generally use wheat as their staple cereal. In such communities disease due to faulty nutrition is not a major problem. At

present there is no nutritional reason for advocating the increased consumption of wheat among the advanced peoples of European and North American countries, and in the interests of public health the surplus wheat should be used as a feed for stock, thus converting it into the nutritionally superior commodities milk, butter, eggs, and meat. The traditional dietary habits of rice- and corn-eating peoples might profitably be changed in favor of a larger consumption of wheat.

Shortening value and flavor of culinary fats (*Indiana Sta. Rpt. 1936, pp. 48, 49*).—This progress report (E. S. R., 75, p. 877) deals with the tenderness and desirability of flavor of wafers made from two open-kettle rendered lards from the fat of hogs fed on known rations, one commercial lard, a commercial hydrogenated vegetable fat, and a partially hydrogenated lard prepared from a lard rendered from the fat of hogs fed on a known ration.

The storage of black-walnut kernels, R. B. DUSTMAN (*Food Res., 1 (1936), No. 3, pp. 247-253*).—In this investigation at the West Virginia Experiment Station of the factors involved in the keeping quality of walnuts, the freshly shelled kernels were dried in the dark for 24 hr. at room temperature to reduce the moisture content from 9.62 to 4.14 percent, packed in wide-mouth glass bottles with screw caps or rubber stoppers and in glass test tubes, and sealed in atmospheres of air, nitrogen, hydrogen, carbon dioxide, and vapors of ethyl alcohol with air or nitrogen. The samples were stored under the temperature conditions of ordinary unheated cellar storage with a range of from -8.3° to 26.7° C., of fruit storage from 0.6° to 2.2° , and of frozen storage from -17.8° to -12.2° . At various intervals of time up to 3 yr. the stored walnuts were judged for palatability by a tasting squad and were examined for rancidity by a modified Kreis test on samples of expressed oil.

The samples stored in sealed glass tubes were generally superior to those stored in bottles. The most satisfactory results from the standpoint of convenience and quality of the product were obtained by storage in an atmosphere of nitrogen at temperatures near the freezing point, which allows the retention of a satisfactory flavor and palatability over a period of 2 yr. or longer. Vacuum, carbon dioxide, or hydrogen may be substituted for the nitrogen, resulting in only a slight lowering in the quality of the stored walnut meats. Any treatment which includes reduced temperature and exclusion of air or oxygen will assist in preserving the original flavor of the nuts.

The control of staphylococci in custard-filled puffs and éclairs, J. STEITAR, G. M. DACK, and F. G. JUNGWAEELTER (*Food Res., 1 (1936), No. 3, pp. 237-246, figs. [5]*).—A method is described for the pasteurization of custard-filled puffs and éclairs to destroy *Staphylococcus aureus* organisms if present in the filling without impairing the flavor or appearance of the pastries. The most satisfactory results were obtained when the filled products were reheated uncovered in the oven at temperatures ranging from 375° to 425° F. a 30-min. period. The crispness of day-old shells was renewed by the reheating.

[Nutrition studies by the Illinois Station] (*Illinois Sta. Rpt. 1935, pp. 289-294*).—Progress reports (E. S. R., 74, p. 568) are given on studies by C. R. Meyer in continuation of attempts to identify an unknown factor essential for lactation present in certain parts of oats and in hydrogenated cottonseed oil by J. Outhouse and Meyer on the relative vitamin A value of several varieties of yellow corn and on the value of carotene in comparison with halibut-liver oil as a source of vitamin A for children as determined by the Jeans test, using a Birch-Hirschfeld visual photometer, and by Outhouse in continuation of the investigation of the bone-calcifying properties of lactose.

The relation of season, sex, and weight to the basal metabolism of the albino rat, T. C. SHERWOOD (*Jour. Nutr.*, 12 (1936), No. 3, pp. 223-236).—The author reports 1,962 basal metabolism tests made on 70 male and 100 female adult normal rats receiving a well balanced dry ration supplemented with fresh whole milk and green plants, and kept in an environmental temperature of approximately 26° C. A modification of the Haldane open circuit type of apparatus was used, and the tests were made after an 18-hr. fast during a 3-hr. testing period.

The results did not show a seasonal variation in basal metabolic rate in all weight groups. The adult rats weighing above 180 g showed a somewhat lower basal metabolism during the summer months. When measured in calories per unit of surface area, a 26-percent decrease in heat production was shown in the animals ranging in weight from 100 to 420 g. When measured in calories per kilogram of body weight, a 42-percent decrease was shown for the same weight group. A comparison between 50 males and 50 females of equal weight demonstrated that in the larger animals there was a slightly higher heat production in the male than in the female, while the young animals had approximately the same basal metabolic rate. During active sexual life the basal metabolic rates of male and female rats varied, and as the rats approached the end of the period the rates became approximately the same.

The heat produced was calculated for surface area, using the Dack formula,¹ as well as for weight. The weight technic proved to be slightly the more reliable.

Increase in height and weight and decrease in age of college freshmen over a period of twenty years, L. B. CHENOWETH (*Jour. Amer. Med. Assoc.*, 108 (1937), No. 5, pp. 354-356, figs. 3).—From records of the physical measurements of students of the University of Cincinnati, data have been tabulated by sex on the average height, weight, and age of 8,963 young men and 4,124 young women entering the university each year from 1916 to 1935, inclusive.

The results show that the entering students are younger, taller, and heavier now than 20 yr. ago. These findings are thought to indicate that "a definite racial betterment is taking place in the United States, and that the improvement is only partially influenced by social and economic position."

Basal metabolism of normal young men and women of various races in Hawaii, C. D. MILLER and F. G. BENEDICT (*Hawaii Ter. Med. Assoc. Ann. Mtg., Trans.*, 46 (1936), *Sci. Sess.*, pp. 27-29).—This is a brief report of an extensive study at the University of Hawaii of the basal metabolism of 115 men and 122 women between the ages of 18 and 30 yr. of the following racial groups: Japanese, Chinese, Caucasian, Chinese-Hawaiian, and Hawaiian mixtures. The work is a part of the world-wide survey of basal metabolism sponsored by the Nutrition Laboratory of the Carnegie Institution of Washington. The tabulated data, grouped by race for men and women separately, show a minus deviation from the Harris-Benedict prediction standards for all racial groups, with a greater deviation for females than males. Of the females, the greatest deviation was -15 for the Chinese and the least -7.3 for the Hawaiian mixed group. The value for the Chinese women confirms previous work of Benedict and coworkers indicating that Chinese women have a definitely lower basal metabolism than Caucasian women.

Cholesterol feeding and fat metabolism, R. P. COOK (*Biochem. Jour.*, 30 (1936), No. 9, pp. 1630-1636, figs. 4).—In this preliminary experiment the author studied the action of cholesterol in producing disorders of fat metabolism in rats

¹ *Jour. Nutr.*, 3 (1930), No. 3, pp. 259-296.

and guinea pigs. Groups of rats were maintained on fat-free and normal synthetic diets supplemented by approximately 0.25 g daily of a commercial preparation of cholesterol. The guinea pigs received a stock diet containing a small amount of fat and supplemented by approximately 0.8 g of cholesterol per day.

The cholesterol feedings caused a decreased growth rate and the development of fatty livers only in those rats receiving a diet containing fat. The rats on the fat-free diets showed no effects due to the absence of absorption. The guinea pigs proved to be very susceptible to the action of cholesterol, and fatty livers were produced in animals receiving the low fat diet. The action of cholesterol appeared in part to be the mobilization of fat in the liver, accompanied by a marked decrease in depot fats.

Respiration and ketogenesis in the "cholesterol" fatty liver, R. P. COOK and N. L. EDSOY (*Biochem. Jour.*, 30 (1936), No. 9, pp. 1637-1639).—In continuation of the study noted above, the changes resulting from the feeding of cholesterol were studied further. Respiration and ketogenesis of control and of cholesterol-fed animals were studied both in the presence and absence of sodium butyrate. The rats receiving a fat-free diet and the guinea pigs receiving the stock diet supplemented by cholesterol failed to develop fatty livers during the short experimental period. After feeding fat-free diets supplemented by cholesterol for longer periods, the liver tissues of the rats showed a significantly lower response in the presence and absence of sodium butyrate, whereas there was no significant change of respiration noted in the guinea pigs, but the ketone body formation in the presence of the substrate was decreased. The "spontaneous" ketone body formation found in the livers of the animals receiving the fat-free diet plus cholesterol was less than in the livers of rats starved for 24 hr. In general the changes noted were small.

Vitamin content of important foods in the child's diet, C. R. FELLERS (*Amer. Jour. Pub. Health*, 25 (1935), No. 12, pp. 1340-1345).—This article, which constitutes Contribution 222 of the Massachusetts Experiment Station, is a short summary of some of the results obtained at the station in vitamin content studies on foods of special importance in the diet of infants and children. These studies have been noted from other sources.

Further studies of the content of vitamins A and B in canned strained vegetables, F. HANNING (*Jour. Amer. Dietet. Assoc.*, 12 (1936), No. 3, pp. 231-236; *abs. in Michigan Sta. Quart. Bul.*, 19 (1937), No. 3, p. 196).—In continuation of the studies on the vitamin content of canned strained foods of a single brand (*E. S. R.*, 73, p. 853), several vegetables were examined for their vitamin A content by the method of Sherman and Munsell and for their vitamin B content by the Chase and Sherman method, using rat harnesses to prevent coprophagy.

The range of vitamin A values for the 1932 and 1933 products, expressed in international units per ounce were as follows: Spinach from 3,339 to 3,594, carrots from 1,792 to 1,887, tomatoes from 1,105 to 1,326, peas from 270 to 327, and green beans from 196 to 344 units. These values do not vary greatly from the 1930 and 1931 determinations except for the increase in vitamin A potency of peas and green beans.

The range of vitamin B values for the 1934 products, expressed in international units per ounce, were as follows: Tomatoes from 7 to 12.1, peas 8.2, carrots 3, green beans 3, beets 1, and spinach 1.6 units. All the vitamin B values were higher than those reported for the 1932 products. This increase may be due to an improved method of canning or a seasonal variation in the raw vegetables, or both.

The influence of vitamins A, B, or D, anemia or fasting upon the rate of fat absorption in the rat, M. H. IRWIN, H. STEENBOCK, and A. R. KEMMERER (*Jour. Nutr.*, 12 (1936), No. 4, pp. 357-364).—In continuation of a series of experiments conducted at the Wisconsin Experiment Station (E. S. R., 77, p. 132), the authors determined whether the rapid absorption of halibut-liver oil, hydrogenated fat (vegetable shortening), and vegetable salad oil may be attributed to their vitamin A and D contents. The effects of vitamin B, anemia, and fasting on the rate of absorption were also determined. The technic previously described was followed, using the 4-hr. absorption period.

The fats and oils tested on normal adult rats and their relative absorptions were untreated halibut-liver oil 70 percent, halibut-liver oil aerated to destroy vitamin A 58, aerated halibut-liver oil with 28,000 blue units of vitamin A added 54, hydrogenated vegetable oil 54, and hydrogenated vegetable oil with 23,400 blue units of vitamin A 49 percent.

The effect of vitamin A depletion in the animals on the rate of absorption was tested on young rats which had been kept on a vitamin A-free diet for 7 weeks. The absorption values obtained for these were hydrogenated fat 30 percent and hydrogenated fat plus 26,400 blue units of vitamin A 31 percent. Normal controls of about the same weight absorbed 56 percent of the untreated fat. These results indicate that the addition of vitamin A to a fat does not affect its rate of absorption by normal rats, but that rats deprived of vitamin A absorb fat less readily than normal animals.

Similar results were obtained for vitamins B and D. The addition of either of these vitamins to a fat had no effect upon its absorption by normal rats, but rats depleted of the vitamin absorbed the fats less readily. However, anemic rats, others fasted 6 days, and others fed a limited quantity of a complete diet also absorbed fat less readily than normal animals, and the addition of these vitamins to a fat has no effect upon the rate of absorption by normal rats. It is evident that a decreased rate of absorption in avitaminosis may be ascribed secondarily to a poor physical condition due to faulty nutrition rather than to the specific lack of vitamin A, B, or D.

The influence of certain hydrotropic and other substances upon fat absorption, M. H. IRWIN, J. WEBER, and H. STEENBOCK (*Jour. Nutr.*, 12 (1936), No. 4, pp. 365-371).—Following the technic previously described, a commercial hydrogenated vegetable shortening was used as the base fat and was followed immediately by 1 cc of a water solution of the substance being tested.

The control animals receiving the hydrogenated fat alone showed an absorption value of 54 percent, and those receiving the fat followed by 1 cc of distilled water absorbed 55 percent. The following fat absorption values were obtained when 1 cc of distilled water containing the test material was fed immediately after the 1.5 g of hydrogenated fat: 1 mg of commercial bile salts 53 percent, 1 mg of sodium benzoate 50, 5 percent of ethyl alcohol 51, 1 g of peptone 27, 1 g of sucrose 33, 1 g of peptone plus 1 g of sucrose 25, 0.2 mg of potassium chloride 48, 0.2 mg of calcium chloride 54, 2 mg of sodium acid phosphate 47, and 2 mg of sodium glycerophosphate 47 percent. When 50 mg of bile salts, sodium benzoate, or sodium glycerophosphate were fed, the absorption values were, respectively, 55, 38, and 38 percent. When 100 mg of potassium chloride or calcium chloride were given, the absorption values were, respectively, 34 and 26 percent. Feeding 10 percent of glycerol gave an absorption value of 43 percent and 40 percent of ethyl alcohol 27 percent. The administration of 500 mg of bile salts, sodium benzoate, and sodium glycerophosphate gave values of 19, 14, and 29 percent, respectively.

These data indicate that the feeding of small amounts of any of these substances has little or no effect, but larger amounts cause a definite decrease in the rate of fat absorption.

The transmission of vitamin A from parents to young in mammals.—V, The vitamin A and carotenoid contents of human colostrum and milk, W. J. DANN (*Biochem. Jour.*, 30 (1936), No. 9, pp. 1644-1651, figs. 3).—This continuation of the series noted previously (*E. S. R.*, 73, p. 881) presents quantitative data on the vitamin A contents of colostrum and early milk of 42 white and 69 colored women, aged from 14 to 41 yr. and ranging from primiparae to one 11-parous subject. Singles samples of colostrum were obtained shortly after secretion and those of early milk several days later. The diet was poor during pregnancy and liberal after delivery. Cod-liver oil supplement was given to some subjects during pregnancy. The vitamin A and carotenoids were extracted and measured colorimetrically. The results were expressed as yellow units (Y) of carotenoids and blue units (B) of vitamin A and the total vitamin A activity was estimated.

The vitamin A content of colostrum varied from 0 to 2,625 B per 100 cc and the carotenoid content from 20 to 1,540 Y. The estimated total biological activity ranged from 56 to 2,172 international units per 100 cc. The vitamin A and carotenoid contents of the colostrum were of the same order as in cow's colostrum and could not be correlated with the age of the patient, number of birth after which colostrum was taken, or length of time after birth until colostrum was obtained. The vitamin A content of the colostrum was not increased by regular ingestion of cod-liver oil during pregnancy. The vitamin A content of the milk varied from 0 to 2,000 B and the carotenoid content from 0 to 800 Y per 100 cc. The estimated biological activity ranged from 0 to 1,860 international units per 100 cc. The vitamin A and carotenoid contents of early milk of the women subjects were much higher than those of cow's milk. The ratio of the amounts of vitamin A in colostrum and early milk was less than 3 in 70 percent of the cases studied. Human colostrum apparently has no function in the provision of a reserve supply of vitamin A for the infant at birth.

Evaporated milk: Effect of irradiation on vitamin A content, H. J. CANNON and O. F. HIXSON (*Indus. and Engin. Chem.*, 28 (1936), No. 9, pp. 1009, 1010, figs. 5).—Irradiated and nonirradiated evaporated milks were assayed for vitamin A according to the U. S. P. technic (1934) (*E. S. R.*, 71, p. 533) and using the U. S. P. reference cod-liver oil for the standard. Each sample of the milk tested was a mixture of three nationally known brands. The results were identical, both the irradiated and nonirradiated evaporated milks containing 4.28 U. S. P. units of vitamin A per gram (1,767 units per 14.5-oz. container).

Influence of avitaminosis A on experimentally produced cutaneous infections in rats, T. H. STERNBERG and D. M. PILLSBURY (*Arch. Dermatol. and Syphilol.*, 35 (1937), No. 2, pp. 247-250).—Two groups of young rats receiving a vitamin A-deficient diet consisting of casein 18 percent, agar 2, salt 40 4, yeast 6, dextrinized starch 70 percent, and 3 drops of viosterol per kilogram of diet were infected intradermally with streptococcus and staphylococcus organisms and the severity and duration of the resulting infections were observed. The 10 rats in group A showed definite signs of vitamin A deficiency when inoculated, and group B was composed of 10 normal rats receiving a supplement of 0.2 cc of cod-liver oil three times a week at the time of inoculation.

Definite evidence of a minimal grade infection lasting from 5 to 10 days was noted in 8 rats of group A and 9 rats of group B. "Avitaminosis A in rats has no apparent effect on the resistance of the skin to experimentally produced infection with streptococci and staphylococci."

Vitamin B assay, using rat curative method with modified diets and oral administration of addenda, F. P. DANN (*Jour. Nutr.*, 12 (1936), No. 5, pp. 461-468).—The Ammerman and Waterman modification (E. S. R., 76, p. 423) of the diet used by Smith in the rat curative method for vitamin B₁ has been further modified by the addition of an amount of yeast supplying about one-third of the vitamin B requirement for growth at a rate of 3 g weekly. This was accomplished by adding 400 g of dried dehydrated brewers' yeast (North-western) containing 13.3 Sherman vitamin B₁ units per gram to 100 lb. of the diet. The incidence of polyneuritis was much higher on this diet, there being only 31.1 percent of the animals discarded as compared with 54.8 percent on the Smith diet and 53.7-58.1 percent on the Ammerman and Waterman diet. The technic followed in the test is described, and various precautions necessary to follow for accuracy are listed.

Quantitative estimation of lactoflavin and of vitamin B₆ in cow's milk and in human milk, P. GRÜBER (*Soc. Expt. Biol. and Med. Proc.*, 35 (1936), No. 1, pp. 204-207).—In this investigation, conducted at Cleveland, Ohio, the various supplements to the basal vitamin B-(complex) free diet were crystalline vitamin B₁, lactoflavine, and a vitamin B₆ concentrate consisting of a yeast preparation obtained by the Peters method (E. S. R., 70, p. 153), 1 cc of which was equivalent to about 1 rat day dose of vitamin B₆, this term being defined as the minimum quantity of the substance that would cause healing of the specific "dermatitis." Similarly, the rat day dose for the estimation of lactoflavine was defined as the minimum quantity of the substance which would give rise to a gain in weight of about 10 g per week for at least 4 weeks.

Graded doses of from 5 to 15 cc of fresh raw certified and pasteurized milk were fed in place of the flavine and vitamin B₆ concentrate, respectively, to from 4 to 6 rats at each level. The values obtained were compared with previous values reported by the author for milks tested in Cambridge, England (E. S. R., 75, p. 238).

The rat day dose for lactoflavine was about 5 cc for Cleveland milk and 10 cc for Cambridge milk, while that for vitamin B₆ was from 3 to 10 cc for both milks, being slightly higher for the Cleveland milk. The vitamin B₆ values were practically the same for the certified and pasteurized milk tested in Cleveland, and the lactoflavine values for certified milk were slightly higher.

Earlier workers have established the fact that the limiting factors for rats are vitamin B₁ in cow's milk and vitamin G (B₁₂) in human milk. To find which component of vitamin G determines the low potency in human milk, the milk of five lactating women was analyzed and doses varying from 3 to 15 cc of the fresh milk were tested on rats. Since the rat day dose of lactoflavine could not be reached even when 15 cc of the milk were given daily, while the vitamin B₆ unit was found to be about 5 cc, it was concluded that in human milk the lactoflavine represents the limiting factor. The addition of pure crystalline lactoflavine to human milk would increase its vitamin G potency.

Bisulphite binding substances in the blood in health and in disease, particularly vitamin B₁ deficiency, R. W. WILKINS, F. H. L. TAYLOR, and S. WEISS (*Soc. Expt. Biol. and Med. Proc.*, 35 (1937), No. 4, pp. 584, 585).—Data are presented in this preliminary report indicating that determinations of the bisulphite-binding substances in the blood are of no aid in diagnosing vitamin B₁ deficiency, as an elevation of this value is also found in a variety of other diseases.

Vitamin B complex therapy in chronic arthritis, C. LER. STEINBERG (*Amer. Jour. Digest. Diseases and Nutr.*, 3 (1936), No. 10, pp. 765, 766).—This is a study of the effect of administering vitamin B complex to 105 patients with atrophic

and 13 patients with hypertrophic arthritis, showing symptoms of gas, constipation, and anorexia, with occasional diarrhea, heartburn, and epigastric pain present in some cases. "Vitamin B complex" in doses of from 4 to 12 cc daily was given to 108 patients, 10 received one cake of brewers' yeast daily, and in 3 patients the vitamin B complex was alternated with 30 cc of a live strain of brewers' yeast.

Within from 1 to 3 weeks the gastrointestinal symptoms were alleviated in over 95 percent of the cases. The cessation of the vitamin administration resulted in the return of the symptoms in about 50 percent of the cases. The administration of large doses of vitamins A and D to 20 cases of chronic arthritis did not change the already improved status of the gastrointestinal symptoms. The vitamin B complex appears to be of adjunct value in the treatment of chronic arthritis.

Comparison of the biological and chemical methods for the determination of vitamin C in canned strained vegetables and a study of its variation from year to year, F. HANNING (*Jour. Nutr.*, 12 (1936), No. 4, pp. 405-412; *abs. in Michigan Sta. Quart. Bul.*, 19 (1937), No. 3, p. 196).—The author presents data obtained during the 5-yr. study referred to on page 421 to show that the chemical method of determining vitamin C by titration with sodium 2,6-dichlorobenzenoneindophenol is accurate and agrees remarkably well with the results of biological tests made on the same samples by the Sherman, LaMer, and Campbell method (*E. S. R.*, 46, p. 865).

The variations in vitamin C content of the vegetables packed from 1930 to 1935 were determined by the same methods, using from 24 to 60 sample cans of each vegetable. A marked variation in potency was noticed, particularly in the tomatoes, which ranged from 64 to 142 international units per ounce. Spinach showed a variation of from 18 to 27 units in the 1930-32 packs and from 50 to 85 units in the 1933-35 packs. The content in green beans varied from 9 to 23 units and in peas from 32 to 53 units per ounce in the 5-yr. period. It is concluded that even under carefully controlled conditions the standardization of the vitamin C potency is difficult.

The determination of vitamin C by means of its influence on the body weight of guinea-pigs, K. H. COWARD and E. W. KASSNER (*Biochem. Jour.*, 30 (1936), No. 9, pp. 1719-1727, figs. 2).—A growth method is described for the estimation of vitamin C similar to the method advanced by the author for estimating vitamin A (*E. S. R.*, 68, p. 565), with increase in weight of young growing guinea pigs as criteria. When the accuracy of the method was calculated, it was found to be no greater than that of Hùjer's "tooth structure" method. The relative merits of the two methods are discussed, and it is concluded that the latter has distinct advantages.

Vitamin-C content of dairy orange beverages, M. J. MACK, C. R. FELLEERS, W. A. MACLINN, and D. A. BEAN (*Food Res.*, 1 (1936), No. 3, pp. 223-230).—In this study at the Massachusetts Experiment Station the vitamin C content of 10 dairy orange beverages, with fresh and canned orange juice for comparison, was determined biologically and also by titration with 2,6-dichlorophenolindophenol and with iodine. Good agreement was shown in the results obtained by the three methods. Of the two chemical methods, the iodine titration was found to give the more constant and easily reproducible results. The vitamin C values obtained by the chemical method ranged from 0.003 to 0.093 mg per gram (0.2 to 53 units of vitamin C per ounce) as compared with from 228 to 253 units for fresh and somewhat over 200 units for canned orange juice.

The losses of vitamin C on storage were also determined for 2 of the dairy orange beverages. At room temperature the losses were rapid and extensive. At cold storage temperatures the losses were much less but still significant.

These findings indicate that at best dairy orange beverages are only fair antiscorbutics and cannot be considered satisfactory substitutes for fresh or canned orange juice.

The vitamin C content of the human tonsil, M. M. CLAYTON and J. D. KEITH (*Science*, 84 (1936), No. 2128, pp. 377, 378).—Vitamin C values ranging from 10.6 to 47.6 mg of ascorbic acid per 100 g of tissue were found in the analysis of tonsils of 54 persons, mostly children, on the day of tonsillectomy. The average value was 24 mg, with a standard deviation of 6.4 mg. The tonsils of 3 children who had been given 400 cc of orange juice daily for periods of from 5 to 12 days before the operation had an average vitamin C content of 42.9 mg per 100 g of tissue. In one of these subjects the urinary excretion of vitamin C for the 24 hr. immediately preceding the operation was 140 mg. As the subject had been taking 400 cc of orange juice daily, containing approximately 240 mg of vitamin C, for 11 days preceding the operation, it is thought that the tissues must have been saturated with vitamin C at the time of operation.

Combined ascorbic acid in food-stuffs, B. C. GUHA and J. C. PAL (*Nature [London]*, 137 (1936), No. 3475, p. 946).—Conflicting observations of the state in which ascorbic acid is present in certain natural foodstuffs are reviewed briefly, and evidence is summarized which, in the opinion of the authors, demonstrates "almost conclusively that the increase of the vitamin C value of certain foodstuffs on boiling cannot be accounted for on the oxidase theory, and that part of the vitamin in the natural foodstuffs is present in the combined state." The evidence is essentially as follows:

When cabbage is treated with absolute alcohol in the presence of anhydrous sodium sulfate, an extract is obtained which, when heated for 4 min. on a boiling water bath in an atmosphere of nitrogen, invariably gives an increase in vitamin C value as determined titrimetrically on the order of from 50 to 100 percent. Heating the extract similarly at 36° C. for 10 min. gives a considerable increase in vitamin C value, often of the order of 50 percent. An extract similarly prepared with ether instead of alcohol in the presence of anhydrous sodium sulfate gives no test for vitamin C, but when heated in an aqueous medium in a boiling water bath for 4 min. in an atmosphere of nitrogen gives a considerable vitamin C value even if the titration is carried out after mercuric acetate or formaldehyde treatment to remove interfering substances. A common Indian fruit, bel (*Aegle marmelos*), was said to give similar results as cabbage, although the increase was not so marked. Ripe and unripe mangoes do not show an increased vitamin C value under the same treatments.

The state of ascorbic acid in plant tissues, G. L. MACK (*Nature [London]*, 138 (1936), No. 3490, pp. 505, 506).—In this contribution from the New York State Experiment Station the various explanations which have been advanced for the apparent increase in the amount of titratable ascorbic acid in some plant tissues after being heated in boiling water are discussed, with particular emphasis on the earlier observation of Tillmans et al. (*E. S. R.*, 69, p. 8) that with certain vegetables the titrimetric method agrees with the biological only if the oxidized ascorbic acid is reduced with hydrogen sulfide, and the further observation that this oxidation, which occurs during the extraction, may be prevented by heating before extraction or by extraction with stronger acid. The reports of Ahmad (*E. S. R.*, 76, p. 426) and of Guha and Pal noted above are cited as showing that the facts brought out by Tillmans et al. have been overlooked by later workers.

Data are reported on a repetition of the experiments with cabbage of Guha and Pal. These are in agreement with the observation of Tillmans et al. and

in disagreement with those of Guha and Pal. The samples of cabbage examined by the author "did not contain appreciable amounts of ascorbic acid in a combined state. If the enzyme is inactivated by heat or alcohol, or inhibited by extracting with sufficiently strong acid, the total amount of ascorbic acid is obtained. The fact that practically none of the ascorbic acid is recovered by acidifying or heating an aqueous extract indicates that nearly all the apparent increase on cooking is due to the inactivation of the enzyme."

Intramuscular injection of ascorbic (cevitamic) acid and excretion in the sweat. A. LILLENFELD, I. S. WRIGHT, and E. MACLEATHEN (*Soc. Expt. Biol. and Med. Proc.*, 35 (1936), No. 1, pp. 184-189, figs. 4).—Afebrile patients of varying ages and degrees of vitamin C saturation were used as subjects. Following determination of the content of cevitamic acid in urine and blood, 4 cc of a solution containing 200 mg of the vitamin was injected intramuscularly daily for 3 days, and urine samples were collected every hour for 3 hr. and as passed for the remainder of the 24-hr. period. On the third day three hourly blood specimens were taken.

In cases in which the dietary history showed a good vitamin C intake and the initial values for urinary excretion and blood level were high, the first injection was followed by an immediate increase of cevitamic acid in the urine which persisted throughout the experimental period. Where the vitamin C intake had been only fair and the initial values for urinary excretion and blood level were correspondingly reduced, the increase in urinary excretion was not so pronounced. With an inadequate C intake and very low initial values, injections did not raise the urinary excretion. Low C values noted in a subject perspiring profusely suggested possible excretion in the sweat.

In all three groups the blood level of cevitamic acid was increased, the peak being reached and maintained on the first and second hours after injection and dropping rapidly in the third hour toward the initial level. The height of increase in the blood level was reached more slowly and maintained for a longer time following intramuscular than intravenous injections of cevitamic acid. Intramuscular injections are recommended in cases where cevitamic acid is improperly absorbed through the gastrointestinal tract or where intravenous administration is not possible.

Some observations on the reduction of iron by tissue extracts and by ascorbic acid, with a note on the stabilization of ascorbic acid solutions. W. D. McFARLANE (*Biochem. Jour.*, 30 (1936), No. 3, pp. 1472-1478).—In a series of experiments with guinea pigs receiving the Harris scurvy-producing ration (E. S. R., 67, p. 650), the author observed that the daily injection of 3 mg of ascorbic acid cured the secondary anemia associated with the scurvy. It is suggested that ascorbic acid may play a role in iron metabolism by reducing the ferric iron of the blood prior to its storage in the liver in the reduced form.

The ascorbic acid content of several tissues was estimated by means of their reducing capacity for 2,6-dichlorophenolindophenol and ferric iron, and it was shown that in each tissue there was sufficient ascorbic acid to retain all the iron in the ferrous form. From the results of experiments in vitro on the reduction of ionic iron, iron in combination with protein, ferric lactate, and ferric glutamate by ascorbic acid, it would appear that some iron-protein compound is involved in the reduction of tissue iron in vivo by ascorbic acid.

The following materials in order of decreasing activity were shown to protect ascorbic acid from copper catalysis: Sodium diethyldithiocarbamate, cystine, cysteine, and glutathione. The addition of $\alpha\alpha'$ -dipyridyl and sodium diethyldithiocarbamate together inhibited the aerobic oxidation of ascorbic acid in orange juice. Glutathione had practically the same effect.

The estimation of reduced ascorbic acid in blood serum and plasma, F. H. L. TAYLOR, D. CHASE, and J. M. FAULKNER (*Biochem. Jour.*, 30 (1936), No. 7, pp. 1119-1125, figs. 2).—A method for the estimation of small amounts of reduced ascorbic acid in blood is described. This is said to have no interference from phenols, uric acid, amino acids, urea, creatinine, and glucose under the conditions of the experiment, although, as has been previously reported by Harris and Ray (*E. S. R.*, 70, p. 426), there is interference from thiosulfate.

Determinations by this method on the blood serums of 33 normal persons gave reduced ascorbic acid content values ranging from 0.83 to 2.43 mg. with an average of 1.61 mg per 100 cc. In 10 scorbutic subjects 8 showed values below 0.4 mg, while 2 showed values of 0.42 and 0.55 mg per 100 cc, respectively. When 1 g of ascorbic acid was administered orally to a normal young adult, the fasting serum level changed from 1.57 to 2.29 mg in 1 hr. and returned in 5 hr. to approximately the initial level. At a later period 1 g of the vitamin was injected intravenously into the same subject when the fasting blood serum level was 1.21 mg per 100 cc. In 30 min. the serum value was 3.49 mg, in 2 hr. 2.17, and in 4 hr. 2.3 mg. Upon the intravenous administration of 1 g of ascorbic acid into a scorbutic patient, the blood serum level rose from 0.61 to 2.58 mg in 30 min., and in 1½ hr. fell to 1.24 mg, where it remained for at least 48 hr. Later when 1 g of ascorbic acid was given orally to the same subject maintained on a vitamin C-free diet, the serum level changed from 1.14 to 1.7 mg in 3 hr., and within 24 hr. had returned to approximately the initial level.

Toxic secondary actions of ascorbic acid—hypervitaminosis C? [trans. title], F. WIDENBAUER (*Klin. Wchnschr.*, 15 (1936), No. 53, pp. 1158, 1159).—The administration of test doses of ascorbic acid (Redoxon) varying from 100 to 6,000 mg to 29 infants, 93 preschool and school children, and 20 adults gave rise to secondary toxic symptoms in only 5 adults and 4 infants. The author concludes that these 9 cases possessed a special sensitivity to vitamin C.

An outline of studies relating to vitamin C deficiency in rheumatic fever, J. F. RINEHART (*Jour. Lab. and Clin. Med.*, 21 (1936), No. 6, pp. 597-608).—The author reviews the experimental basis for the concept that rheumatic fever may be the result of the combined influence of vitamin C deficiency and infection (*E. S. R.*, 71, p. 429), summarizes further experimental studies confirming and extending the original findings and certain epidemiological and clinical observations bearing on the problem, and discusses the essential pathology of rheumatic fever and vitamin C metabolism with relation to vitamin C therapy in rheumatic fever. Two approaches to the final solution of the problem are suggested—(1) to determine if optimal vitamin C nutrition over an adequate period of time will prevent susceptible groups from getting rheumatic fever, and (2) to determine if a high vitamin C intake by rheumatic children over a long period of time will materially reduce the tendency to recurrence.

The inverse relation between growth and incidence of cataract in rats given graded amounts of vitamin G-containing foods, P. L. DAY and W. J. DARBY (*Jour. Nutr.*, 12 (1936), No. 4, pp. 387-394, fig. 1).—In continuation of previous studies (*E. S. R.*, 72, p. 730), series of vitamin G assays were made on a number of food materials. About 200 young rats were fed the vitamin G-deficient diet No. 625 which was previously described. At the end of 2 weeks each animal was given a predetermined weighed amount of one of the test foods, 3 or 6 times weekly for 8 weeks. The control animals received no supplement and were observed until death. The food materials fed included several kinds of cheese, liver extract, yeast, lamb, pork, pork liver, ham, and bacon.

The rats receiving the vitamin supplement, grouped according to growth during the 10-week period, showed the following incidence of cataract: Rats gaining 20 g or less, 39 percent developed cataract: 21–40 g, 26 percent; 41–60 g, 14 percent; and more than 60 g, 0 percent. Of the control animals, 86 percent developed cataract before death, with 63 percent of the group showing eye changes during the 10-week period. An inverse relationship evidently exists between growth and the appearance of cataract. The data indicate that only a small amount of vitamin G is required to prevent cataract, and that growth is a measure of the cataract-preventive property of the vitamin supplement.

Blood sugar in rats rendered cataractous by dietary procedures, P. L. DAY (*Jour. Nutr.*, 12 (1936), No. 4, pp. 395–404, fig. 1).—The experiments of Mitchell and Dodge (E. S. R., 74, p. 418) on the production of cataract in rats fed on high lactose rations were repeated to determine whether animals receiving high percentages of galactose and lactose would show significant hyperglycemia when compared with animals receiving other common glycogen-forming carbohydrates. Young rats were given an adequate diet containing various carbohydrates as 60 percent of the diet, with 18 percent casein, 4 percent salt mixture, 2 percent cod-liver oil, 6 percent fat, and 10 percent dried yeast. The Folin micromethod was followed for the blood sugar determinations by tail bleeding. Carbohydrate tolerance tests were made upon representative litter mates receiving different carbohydrates. Weight, food intake, and ophthalmoscopic records were made weekly. Other groups of young rats were given the vitamin G-deficient diet No. 625, with litter mates receiving a dried yeast supplement.

Seventeen out of 18 rats receiving lactose developed cataract at an average time of 44 days. Three rats receiving galactose exhibited cataract on the eleventh day and also showed the highest blood sugar level. The mean of 27 blood sugar determinations upon galactose rats was 372 mg, and the highest level was 556 mg as compared with 160 mg for the mean of 89 determinations upon lactose rats and the highest value of 234 mg. Glucose, sucrose, and starch did not cause cataract. A different kind of cataract was produced in the young growing rats receiving the vitamin G-deficient diet. The mean of 40 determinations of the blood sugar level upon 21 vitamin G-deficient rats was 107 as compared with 118 for 38 determinations upon 9 normal control rats. The cataract resulting from lactose or galactose feeding, especially during the early stages, is quite different in appearance from the cataract caused by avitaminosis.

The cataract-preventive vitamin (flavin) in cheese, P. L. DAY and W. J. DARBY (*Food Res.*, 1 (1936), No. 4, pp. 349–355, figs. 4).—Three kinds of cheese were assayed for flavine, using growth and the prevention of cataract as the criteria for the presence of the vitamin and following the biological method described above, with American and Swiss kinds of cheese fed at 0.2, 0.4, and 0.8-g and cream cheese at 0.4, 0.8, and 1.6-g levels to groups of from 7 to 9 rats.

Expressed in Bourquin-Sherman units per gram, the contents of flavine were found to be for American cheese 2 units, Swiss 1.5, and cream cheese 0.86 units. Calculations based on unpublished preliminary data which indicated that 4 μ g of lactoflavine are approximately equivalent to 1 Bourquin-Sherman unit of vitamin G gave the following values: American cheese, 8 μ g of lactoflavine per gram, Swiss 6, and cream cheese 1.4 μ g per gram. Since a high incidence of cataract was noted among the groups of rats receiving small cheese supplements, and since from 86 to 100 percent of those maintained on the basal ration unsupplemented also developed cataract, it was concluded that

the flavine is "cataract preventive" as well as "growth-promoting." The incidence of cataract was markedly reduced and greater growth resulted when the larger amounts of cheese were fed.

HOME MANAGEMENT AND EQUIPMENT

Index numbers of the cost of goods and services bought by farm families in New York, 1920 to 1935. H. CANON and M. ROLLINS ([*New York*] *Cornell Sta. Mem.* 199 (1937), pp. 23, figs. 5).—The construction of the index numbers presented was undertaken to obtain a measure of the relative changes from year to year in the cost of goods and services bought by New York farm families. The items included in the index are food, clothing, furniture and furnishings, fuel and light, miscellaneous, and all items. Tables are given showing the individual articles used for each item, with the weights assigned, and other pertinent data.

On the basis of 1913 values as 100, the index of all items rose to 191.8 in 1920 and reached its lowest point, 117.9 in 1933, rising again to 134.9 in 1935. In 1920 the indexes for food, fuel, and light, and miscellaneous items were somewhat lower and for clothing and furniture and furnishings higher than the average for all items. The lowest levels for foods, 90.5, clothing, 102.1, and furniture and furnishings, 106.4, were reached in 1933. The index number for fuel and light showed a slight but steady decrease from the high point of 185.6 in 1920 to 152.7 in 1935. The index number for miscellaneous items reached a peak of 215.9 in 1930 and was at 194.8 in 1933, when most of the items were at their lowest figures.

A comparison of the index numbers of farm prices in New York for the years 1920–35 with the index numbers for all items in the present study showed that in only 4 yr.—1920, 1926, 1928, and 1929—did a given quantity of selected New York farm products purchase as much of a given quantity of goods and services for family living as in 1913. The greatest difference was in 1932 when the exchange value, on the basis of 1913 as 100, was only 61. In 1935 this value had reached only 75.

Home accounts help families plan saving and spending (*Illinois Sta. Rpt.* 1935, pp. 300–306, fig. 1).—This progress report on a continuation of the home account studies of R. C. Freeman and P. Nickell (*E. S. R.*, 74, p. 574) summarizes the expenditures for 1934–35 of 231 farm families, of whom 100 had been keeping home account records for 3 yr., 42 for 5 yr., and a small number for 8 yr. The realized incomes and their distribution among various items of family living are compared for the entire number of farm families with the corresponding figures for 167 families in 1933–34, and the distribution of cash expenditures by 100 families who had been keeping accounts for at least 3 continuous years with the corresponding distribution in their records for 1933–34 and 1932–33.

Refrigeration for the farm household and farm produce (*Indiana Sta. Rpt.* 1936, p. 48).—This progress report summarizes the results of a survey of 144 rural homes in the State to obtain information on the adequacy of present refrigeration for the food supply of the farm household and farm produce.

The evolving house.—III, Rational design. A. F. BEMIS (*Cambridge: Mass. Inst. Technol.*, 1936, pp. XXV+ 625, pl. 1, figs. [205]).—This volume of this series (*E. S. R.*, 72, p. 428) contains chapters on efforts toward rational housing, what is rationalization, mass production and the house, standardization for house parts, the cube as a module, the theory of cubical modular design, applied cubical modular design, and cubical module in architectural

design, rational production, patents and the cubical modular method, and social significance of the cubical modular method. It also contains appendices on rectangularity of housing, comparative cost of inclined and flat roofs, multiple openings of various sizes and their relations to symmetry in modular walls, and modular patents; and a supplement entitled *Survey of Efforts to Modernizing Housing Structure*, by J. Burchard 2nd (pp. 327-625).

Recent developments in dwelling construction (*Fed. Housing Admin. Tech. Bul. 1, rev. (1937), pp. 17*).—This report represents the approach which is being made to better construction at lowered costs and an evaluation of the work which has been done, together with tentative conclusions as to its probable effect on the dwelling market. Brief descriptions of the different materials and methods of construction which are being tried out, together with lists of the individuals and concerns who have been engaged in such work, are also included. This includes some methods developed and used in Europe.

Low-cost housing (*Fed. Housing Admin. Circ. 3, rev. (1936), pp. 30*).—This covers in general terms the procedure involved in the insurance of mortgages on low-cost housing projects and sets forth the administrative rules and regulations governing such insurance.

MISCELLANEOUS

The design of experiments, R. A. FISHER (*Edinburgh: Oliver & Boyd, 1937, 2. ed., pp. XI+260, figs. 5*).—Plans for laying out experiments so that the results can be analyzed statistically are presented with details of agronomic experiments and methods of calculating significance, goodness of fit, and linkages in genetic studies.

A year's progress in solving farm problems of Illinois: [Forty-eighth Annual Report of Illinois Station, 1935], compiled and edited by F. J. KEILHOLZ (*Illinois Sta. Rpt. 1935, pp. 331, figs. 40*).—The experimental work not previously referred to is for the most part noted elsewhere in this issue.

Forty-ninth Annual Report of [Indiana Station], 1936, J. H. SKINNER and H. J. REED (*Indiana Sta. Rpt. 1936, pp. 95, figs. 33*).—The experimental work not previously referred to is for the most part abstracted elsewhere in this issue.

Agricultural research through fifty years, 1885-1935 (*Minnesota Sta. Bul. 328 (1936), pp. 111, figs. 14*).—This contains the programs and addresses of the semicentennial celebration of the station (E. S. R., 73, p. 145).

Forty-ninth Annual Report [of Tennessee Station], 1936, [C. A. MOORE ET AL.] (*Tennessee Sta. Rpt. 1936, pp. 72, figs. 27*).—The experimental work reported is for the most part noted elsewhere in this issue.

Forty-sixth Annual Report [of Washington Station], 1936, E. C. JOHNSON ET AL. (*Washington Sta. Bul. 342 (1936), pp. 84*).—The experimental work not previously referred to is for the most part noted elsewhere in this issue.

Index to Technical Bulletins Nos. 1-500, M. G. HUNT (*U. S. Dept. Agr., 1937, pp. 249*).—This is a combined subject and author index.

NOTES

Connecticut State Station.—Dr. George P. Clinton, botanist since 1902 and widely known for his many important contributions to plant pathology, retired from administrative work on July 1 to continue his research and to become consulting botanist.

Kentucky Station.—The resignations are noted of C. J. Bradley, assistant in rural finance; W. K. Hall, assistant chemist; and Ruth McDonald, technician. Recent appointments include Drs. B. J. Errington as pathologist and D. W. Bruner as assistant bacteriologist in the department of animal pathology; Dr. W. S. Hodgkiss, Dr. J. H. Bywaters, Stephen Diachun, and E. J. Nesius as assistants, respectively, in chemistry, animal husbandry, plant pathology, and farm management; and J. J. Rosenberg as microscopist.

Mississippi Station.—Dr. Clarence Dorman, assistant director in charge of research and chief agronomist, has assumed the duties of assistant director of experiment stations formerly assigned to W. R. Perkins. In the substations, E. B. Ferris, extension agronomist, has succeeded the late C. T. Ames as superintendent at Holly Springs, and H. C. McNamara, superintendent of the U. S. Cotton Field Station at Greenville, Tex., has succeeded W. E. Ayres as superintendent at Stoneville.

North Carolina Station.—The 1937 North Carolina Legislature appropriated \$5,000 for apple research work in the Brushy Mountains of the State—an area including some four or five counties in and around Wilkes County. Plans are now under way for constructing a field laboratory in cooperation with the Brushy Mountain Fruit Growers Association. The research work will be under the direction of the horticultural department of the station with the cooperation of the departments of entomology and of plant pathology.

The station is planning a study of farmers' mutual fire insurance companies in North Carolina. An effort will be made, if the project is carried out, to secure records on the management, methods of operation, risks, and reserves of these companies for the purpose of setting up a better form of management and possibly secure the consolidation of operations.

Station workers are presenting brief accounts of their research programs to county agents and other extension workers during a 3-week period at the college this summer.

Pennsylvania College and Station.—The retirement on July 1 is noted of Frank D. Gardner, head of the department of agronomy for 29 years, and J. A. Ferguson, head of the department of forestry for 27 years. Dr. A. L. Patrick, professor of soil technology and soil technologist, resigned June 30 to become associated with the U. S. D. A. Soil Conservation Service.

L. Chester Marston, Jr., recently appointed assistant professor of entomology, died June 21, aged 32 years. A native of Massachusetts, he was graduated from the Massachusetts College in 1923 and received the M. S. degree from the University of Tennessee in 1929. He had been associated with entomological work at the Universities of Delaware and Toronto and was instructor in entomology at the University of Tennessee from 1932 to 1937.

EXPERIMENT STATION RECORD

VOL. 77

OCTOBER 1937

No. 4

THE AGRICULTURAL EXPERIMENT STATIONS IN 1936

According to a report just issued by the Office of Experiment Stations, "the year 1936 represented an epoch in the history of the agricultural experiment stations." Its outstanding event was "the successful inauguration of a program of effective research under the Bankhead-Jones Act, approved June 29, 1935, which materially increased the Federal funds available for station work and the extension of coordinated and cooperative agricultural research on a scale never before attempted." The report, dealing with the work and expenditures of the stations for the fiscal year ended June 30, 1936, appropriately gives much prominence to the Bankhead-Jones activities. It also, however, in much the same way as in former years treats of the use of \$4,395,000 of other Federal funds provided for the support of these stations in the several States, Alaska, Hawaii, and Puerto Rico. It gives the customary general survey of the work of these stations as a whole, discusses their organization, administration, personnel, research facilities, needs, trends, and public service, and reviews the progress made in coordinating their work with that of the U. S. Department of Agriculture and other agencies.

The total income of the stations for the year from all sources was \$16,425,489.71. This was an increase of \$1,353,228, or 8.2 percent, over the previous year and was the highest since 1932. However, it was still \$1,630,793 below the high-water mark of 1931 and approximately the same as for 1929.

The Federal appropriations to the States under the Hatch, Adams, and Purnell Acts were maintained in full, and the initial payments under the Bankhead-Jones Act totaled \$600,000. The income from non-Federal sources, \$11,361,178, was about 69 percent of the total and approximately 7 percent more than that for the preceding year. Of the 53 experiment stations, 40 reported gains from these sources, and in only 1 of the 13 stations reporting reductions were the decreases very significant. The increases in income resulted from net gains of \$559,283 in State appropriations and allotments, \$134,301 in balances carried over from the previous year, \$126,375 in fees,

and \$74,598 in sales receipts, but these were offset to the extent of \$148,705 by decreases in miscellaneous income. During the year many of the stations continued to be benefited also from the expenditure of emergency funds for repairs and improvements of station equipment and from allotments by the Department of Agriculture for cooperative work with the stations.

It will be recalled that unlike the earlier Federal grants, which are apportioned equally among the States, the Bankhead-Jones allotments are made on a basis of rural population. This of course resulted in great variations among the States, the extremes ranging from \$559.12 for Alaska and \$565.96 for Rhode Island to \$33,672.38 for Pennsylvania and \$37,341.19 for Texas. Another innovation of the legislation is its requirement of equivalent offset funds from other than Federal sources. Since the ratio of all Federal to non-Federal funds for the year was 1:2.25, these requirements were readily attainable for the stations as a whole. In certain individual States, however, the ratio was much below this average, and while sufficient in all cases for compliance in 1936, warning is given that as the Bankhead-Jones funds increase in later years there may be some shortages unless additional income from State sources is provided.

The year was productive of considerable improvement of equipment and facilities for research. Expenditures for additions to equipment aggregated \$1,781,321 as compared with \$1,062,257 in 1935, an increase of over 67 percent. Few major structures were built, but in many cases additional land, greenhouses, laboratories, barns, and other accessories were acquired. Provision for libraries rose from \$48,486 to \$53,999.

Although the expenditure for publications increased from \$253.926 to \$257,024, the number of publications in the regular series decreased from 864 to 770. On the other hand, there was a material increase (from 1,778 to 2,665) in the number of articles contributed to outside journals. These articles were distributed among 100 such journals. Thirty-four stations contributed or collaborated in 83 articles published in the *Journal of Agricultural Research*, as compared with 69 articles from 30 stations in the previous year. According to the report, there was "continued and renewed evidence of a growing purpose to make the results of station investigations more widely and readily understood and applied."

With the inauguration of work under the Bankhead-Jones Act, research projects and programs were extended to a wider field of activity than ever before. In all, 7,223 projects were active during the year, providing for research in almost every phase of agriculture and rural life.

The largest number of Purnell projects continued to be in the field of agricultural economics, 360 with an estimated expenditure of \$684,763. Other subjects in which there were a relatively large number of such projects were animal production 240, home economics and horticulture 141 each, entomology 133, field crops 124, and plant pathology 103. In accord with the tendency and the major objective of the plan for expending the Bankhead-Jones funds, 87 or 24 per cent, of these projects were conducted in cooperation with Federal or State agencies.

A total of 360 Bankhead-Jones projects were agreed upon and approved. Approximately one-sixth of the funds was allotted to some 42 projects in agricultural economics concerned with adjustment in production by regions and type-of-farming areas better to meet changing economic conditions, marketing agricultural products including methods and practices, and soil and water conservation and land use. Another one-sixth was assigned to some 60 projects relating to animal production, mainly in the fields of nutrition of the larger animals and poultry, dealing largely with vitamins and mineral nutrition and mostly of fundamental character and broad application. Another line of research receiving the relatively large allotment of about \$68,000 was that dealing with farm pastures and ranges, much of which was coordinated and carried on cooperatively with the Department of Agriculture. About \$62,000 was allotted to projects on breeding and production of field crops, particularly those concerned with plant genetics and breeding for improved quality and varieties, and approximately \$40,000 was assigned to projects in animal genetics.

As usual, the stations worked closely with other State agencies, with local organized groups, with each other in regional groups, and with the Department individually and in regional and national groups in efforts to plan and coordinate their research. In addition to many informal cooperative agreements, some of them of major importance, a total of 818 new or revised formal agreements between bureaus of the Department and stations were proposed. These agreements covered 731 major research undertakings and included all the State experiment stations and all but one of the Department's research bureaus. Seven stations participated formally in the special research program undertaken by the Department from its allotment under the Bankhead-Jones Act (E. S. R., 73, p. 291), and a much larger number in the work of the Bankhead-Jones regional laboratories as previously noted (E. S. R., 75, p. 1).

The increasing trend toward voluntary coordination of effort among research workers on problems of wide importance is shown in the establishment of the Tobacco Disease Council and the Cotton Disease Council, each embracing all interested workers in the States

concerned and in the Department of Agriculture. Conferences were held, arrangements were made for mutual assistance, a future program was developed, and exchange of research outlines, annual reviews of progress, and further group planning were provided for. In a similar way, horticulturists, entomologists, and plant pathologists at the Maryland, Pennsylvania, Virginia, and West Virginia Stations established a combined four-State attack on the orchard spray injury problem. A number of other promising group programs were launched during the year.

Certain regional and national cooperative and research undertakings that had been started on an emergency basis as parts of the national recovery program in 1934 and 1935 were modified and expended to meet more permanent requirements. These studies brought more closely together the parallel interests of plant and soil science research and those of crop and animal production research, with more thorough consideration of their economic and social influences. Studies of adjustments in farming by regions and type-of-farming areas from the standpoint of national agricultural adjustment received considerable attention in this connection, and were typical of the renewed and expanded efforts in cooperative research. It is stated that it was not uncommon to find from 5 to 10 subject-matter departments in a station actively engaged in coordinating their studies to meet both State needs and national adjustment programs.

Following a discussion of group accomplishments and programs, the greater part of the report is again devoted to a review of recent station work, prepared by specialists of the Office from current publications of the stations and communications from station directors and from other authoritative sources. This review is necessarily selective rather than a complete summary of all accomplishments of the stations as a whole or individually, but it is believed to be fairly representative and to indicate especially that the work of the stations "is of value to urban, as well as rural people, and in line with national, as well as local, recovery and adjustment policies." An innovation in the assembling of this material is the inclusion of a detailed subject index. This should measurably increase the usefulness of a publication which is being more and more looked to as an indicator of what the stations are attempting to do and the progress which is being made.

RECENT WORK IN AGRICULTURAL SCIENCE

AGRICULTURAL AND BIOLOGICAL CHEMISTRY

A method of preparing paraffin sections of bone, L. T. DAVID (*Science*, 82 (1935), No. 2121, p. 179).—The author of this contribution from the [Connecticut] Storrs Experiment Station successfully treated pieces of bone as large as 2 by 2.5 cm and by 2 mm thick in accordance with the following schedule:

Decalcification in 5 or 10 percent nitric acid, followed by treatment with 5 percent sodium sulfate solution (2½ hr.) and running water (2½ hr.); dehydration; clearing with equal volumes of absolute alcohol and chloroform, followed by two changes of chloroform; several changes of soft paraffin (m. p. 47° to 49° C.); and embedding in hard paraffin (m. p. 56° to 58°).

Sections cut at 10 μ were mounted by means of a fixative containing 1 cc of standard water-glass solution and 1 cc of concentrated ammonia solution in 100 cc of water. This fixative did not interfere with staining, whereas the gum arabic and potassium bichromate fixative did interfere. "Haemalum" and eosin gave a satisfactory staining.

Rapid weighings with a Troemner solution balance, E. T. BAETHOLOMEW and E. C. RABY (*Science*, 82 (1935), No. 2133, p. 468, fig. 1).—At the University of California, "to avoid the inconvenient, tiresome, and time-consuming method of getting the eye on a level with the pointer end of the beam in order to make a correct reading, two very simple, but very satisfactory, additions were made to the balance. The two additions consist of a damper . . . and two white strips attached to the adjacent projections on the swinging and stationary beams."

The construction of the damper, a very simple device, is described and shown in a drawing. Objects weighing 15 or more kilograms were quickly weighed to an accuracy of 1 g.

[Researches in bacteriological chemistry by the Wisconsin Station] (*Wisconsin Sta. Bul.* 438 (1937), pp. 145, 146, 147, 148).—Recent work by the station is summarized under the following captions: Research casts light on problems in yeast manufacture, by D. Colingsworth, E. C. Sauder, and I. L. Baldwin; and factors affecting nodule formation in legumes, by J. J. Reid and Baldwin.

Some quantitative relationships in bacterial population cycles, M. W. JENNISON (*Jour. Bact.*, 30 (1935), No. 6, pp. 603–623, figs. 7).—It has been shown that "curves of bacterial population cycles are sigmoid but are not symmetrical about their point of inflection. The presence or absence of a lag period in subcultures at the same temperature, with bacteria whose optimum is about 37° C. but which are being cultivated at 22°, seems to be dependent, other conditions being equal, upon factors other than the age of the inoculum." A number of other quantitative observations are recorded.

A comparative study of several strains of the so-called radiobacter, F. B. SMITH and P. E. BROWN (*Iowa State Col. Jour. Sci.*, 10 (1935), No. 1, pp. 17–25, fig. 1).—At the Iowa Experiment Station 8 strains of *Bacillus radiobacter* were secured from various laboratories in the United States, and 16 were isolated

from Iowa soils. Studies on the morphological, cultural, and physiological characteristics were made. "No differences great enough to differentiate species were obtained, and it was concluded that all cultures represent a single species."

The production of furfural from xylose solutions by means of hydrochloric acid-sodium chloride systems, E. I. FULMER, L. M. CHRISTENSEN, R. M. HIXON, and R. L. FOSTER (*Jour. Phys. Chem.*, 40 (1936), No. 1, pp. 133-141).—The authors of this contribution from the Iowa State College report on the production of furfural from strong xylose solutions using hydrochloric acid-sodium chloride solutions as dehydrating agents.

"The xylose-hydrochloric acid-sodium chloride systems were refluxed, at atmospheric pressure, with toluene. The furfural yield was determined from the specific gravities of the resulting furfural-toluene solutions. The concentrations of hydrochloric acid used were 0.25, 0.5, 0.75, 1, 1.5, and 2 N, each in the presence of 0, 5, 10, 15, 20, 25, 30, 35, 40, and 45 percent sodium chloride. The yield of furfural was twice as great for 4 percent xylose as for 60 percent xylose. Detailed experiments were performed for xylose at 20 percent concentration for which the yield in furfural is about 20 percent less than for 4 percent xylose. The yield of furfural is increased about one-third for each 5 percent addition of sodium chloride up to a furfural yield of about 22 percent. From this point the increase in yield is less. For all cases, for a given time period, the yield of furfural is, within reasonable limits, dependent only upon the pH of the hydrochloric acid-sodium chloride combinations. That is, the yield is dependent upon the thermodynamic degree of dissociation of the acid (the activity coefficient)."

The similarity between the mechanism of the rennin and pectase (pectin-methoxylase) reactions, A. C. DAHLBERG and Z. I. KERTESZ (*Science*, 85 (1936), No. 2142, p. 56).—The authors of this contribution from the New York State Experiment Station call attention to the striking resemblance between the reaction of the coagulation of milk by rennin and the formation of a gel from pectin under the influence of pectase. In part it is noted that "in both cases the enzyme causes a slight degradation of the molecule, which also is the first step in the enzymic decomposition of the substrates. In the absence of calcium (Sr, Ba, etc.) no visual evidence of the enzyme action occurs. In the presence of or upon the addition of calcium, however, the paracasein in milk and pectic acid produced from pectin both form insoluble salts, and a coagulum or gel appears."

A quantitative method for the assay of vitamin D with chickens, O. N. MASSENGALE and C. E. BILLS (*Jour. Nutr.*, 12 (1936), No. 5, pp. 429-446, figs. 2).—A quantitative method is described for the assay of vitamin D with chickens based on the determination of the femur ash, the significance of the ash percentage being interpreted by comparisons with master response curves either for cod-liver oil or irradiated ergosterol. It appears that equivalent rat units from cod-liver oil and from irradiated ergosterol for chickens are not broadly comparable, their relative efficiency fluctuating widely with varying degrees of calcification. In feeding tests a diet containing a calcium-phosphorus ratio of 2:1 gave good calcification when containing 18 international units of vitamin D as cod-liver oil per 100 g of ration.

Report of the subcommittee on viscosity, E. G. BAYFIELD (*Cereal Chem.*, 12 (1935), No. 5, pp. 532-535).—In a report prepared at the Ohio Experiment Station, the subcommittee named presents MacMichael viscosimeter data to show the effect of crop origin upon the flour viscosities of the 1933 wheat crop, together with the majority opinion of the subcommittee on various details of the technic of the determination.

On the changes of leucosin, gliadin, and glutenin under the action of flour and yeast proteinases, A. V. BLAGOVESHCHENSKI and M. P. YÜRGENSON (*Cereal Chem.*, 14 (1937), No. 1, pp. 103-107).—The authors find that the optimum pH for the action of the natural mixture of proteolytic enzymes of wheat flour extracts on the proteins of wheat gluten are: for leucosin, 3.7 to 4.7; for gliadin, 3.7; and for glutenin, 4.9 to 5.3; that the optimum pH for the action of the natural mixture of proteolytic enzymes of yeast extracts on leucosin is 3.7 to 4.7; on gliadin, 3.7; and on glutenin, 4.9 to 5.3; that the optimum pH values for the action of pure wheat flour proteinase on gliadin and glutenin are identical and equal to from 4.9 to 5.0; and that the optimum pH for the action of pure yeast proteinase on gliadin and glutenin is also the same and equals 3.3 to 4.9.

The splitting of glutenin was found to be less than the splitting of leucosin and of gliadin. It was also shown that the action of pure flour and yeast proteinases is disaggregating rather than proteolytic, since it is accompanied only by insignificantly small increases in amino nitrogen.

The effect of milk solids on fermentation reactions, O. SKOVHOLT and C. H. BAILEY (*Cereal Chem.*, 14 (1937), No. 1, pp. 108-120, figs. 5).—It has been shown at the Minnesota Experiment Station that "proteolytic activity in doughs is not affected by milk solids as judged by applications previously made of available methods, though it is believed that such methods may not measure adequately all types of attacks that proteases may make on the protein complex.

"Diastatic activity in doughs is retarded by the introduction of milk solids due to the effected reduction in H-ion concentration.

"Gas production from fermenting doughs is accelerated by milk solids if sufficient sugar is available. From sugar-deficient doughs made with ordinary commercial flours, milk solids effect a reduction in amount of gas produced due to a retarding effect on diastasis. With certain experimentally milled flours this retarding effect is not in evidence even in systems low in diastatic activity. Such low diastatic activity may be due to a low starch susceptibility to diastase attack not adversely affected by addition of milk solids."

The use in doughs of yeast treated to inhibit growth gave results indicating that milk solids increase the activity of the yzmase complex. This activation of yzmase by milk solids appeared to be due partially to reduction in H-ion concentration. Other stimulating effects of milk solids upon fermentation by yzmase from yeast were also noted.

The wheat meal time fermentation test, C. O. SWANSON and J. H. PARKER (*Northwest. Miller*, 184 (1935), No. 2, Sect. 2, pp. 14-16).—This brief discussion from the Kansas Experiment Station takes up both the meal and the flour varieties of the time fermentation test from the viewpoint of the breeder who wishes a quick flour strength test applicable to very small wheat samples.

"The 'wheat meal time fermentation test' meets the demands for simplicity. The question of reliability is yet open for discussion. As far as the test has been used, it will definitely separate the 'strong' from the 'weak' wheats. However, when it is attempted to differentiate among those on the border line, the test falls far short of being reliable."

Definition and measurement of "flour strength" as an inherent property of wheat, M. J. BLISH and R. M. SANDSTEDT (*Cereal Chem.*, 12 (1935), No. 6, pp. 653-664, figs. 3).—The authors of this contribution from the Nebraska Experiment Station found that wheats of equal protein content have essentially the same baking potentialities in terms of loaf volume even though they do not all respond equally to any single baking formula and procedure. "Therefore,

for all practical purposes, protein content and inherent flour strength are one and the same thing. The only exceptions to this are to be found in wheats that fail to register responses proportional to their protein contents when subjected to any treatments, singly or combined, that are nowadays at the convenient disposal of both miller and baker. Applying these criteria in our supplementary baking procedures, it will be found that such wheats are rarely, if ever, to be encountered among our established American wheat varieties intended for commercial bread production.

"Strength", as an inherent property, is to be determined not by the baking test but by the protein test. The essential purpose of the baking test is to measure a flour's response to single and combined treatments and environments that are likely to be accorded to it under modern industrial conditions. All possible combinations should be tried, if necessary." With respect to the properties here discussed, "wheats may conveniently be classified into three, or at the most four, groups, with one of these groups predominating."

The baking strength of flour, M. J. BLISH (*Northwest. Miller*, 184 (1935), No. 10, pp. 817, 834, 835).—This paper, from the Nebraska Experiment Station, is "an address before students of the American Institute of Baking."

Refractometric methods of determining diastatic activity of flour, E. MUNZ and C. H. BAILEY (*Cereal Chem.*, 14 (1937), No. 1, pp. 85–96, figs. 7).—A comparative study carried out at the Minnesota Experiment Station showed that flour:water ratios in the range of 1:4 to 1:6 were best adapted to the refractometric method for the measurement of the autolytic hydrolysis of wheat flour. The ratio of maltose content: n_D of the digests became narrower when the flour:water ratio was greater than 1:6. Salts added in the form of citrate buffer solutions apparently reduced the rate of increasing n_D of digests below the rate at equivalent pH levels obtained by adding lactic acid solutions, but buffering materials contributed by low grade flours did not affect the n_D values appreciably. Temperature of digestion of flour suspensions in water influences the maltose: n_D ratio. A linear ratio is approached when the flour suspensions are incubated at 62° to 63° C. At higher temperatures there is a substantial departure from linearity, the n_D increasing faster than the maltose content.

Variability of replicated measurements of n_D was computed in the instance of several series in which variables in the technics were progressively modified. This gave a basis for selection of one technic which provided adequate and convenient chemical and physical conditions and at the same time was least variable. This technic, when applied to duplicated measurements of autolytic hydrolysis in the instance of 10 different flours, resulted in good agreement between the duplicates.

A collaborative study of the Blish-Sandstedt, Schoorl, and Bertrand methods for determining reducing sugars in flour diastatic activity measurements, C. F. DAVIS (*Cereal Chem.*, 14 (1937), No. 1, pp. 74–85, fig. 1).—The more important findings in this comparison of well-known methods were as follows:

"The Blish-Sandstedt, Schoorl, and Bertrand methods for measuring the reducing sugars after diastasis in the diastatic activity test of flour are about equally satisfactory. A slight adjustment in the tables of these three methods in the higher sugar levels would make the values more comparative. The merits of the three methods as indicated by the analysis of the data from this collaborative study would rate them for general use as follows: (1) Schoorl, (2) Blish-Sandstedt, and (3) Bertrand. Because of the greater uniformity between laboratories and a greater differentiation between flours, the Schoorl method is preferable even though it has a higher experimental error than the Blish-Sandstedt method. . . .

"Most collaborators preferred the Blish-Sandstedt method because the ferricyanide reduction in a boiling bath was relatively simple and the experimental error was low."

Atmospheric factors in milling: Principles which make possible the establishment of any desired relative humidity, C. O. SWANSON and J. E. ANDERSON (*Northwest. Miller*, 183 (1935), No. 9, pp. 798, 804).—In this semi-popular note from the Kansas State College "the attempt is made to present some of the principles which make it possible to control or maintain any desired relative humidity. It is not attempted to give specific directions. These must be given by competent engineers and in reference to the conditions in the individual mill concerned. All that will be attempted is to set forth some of the facts to help the millers understand the problem involved." Elementary heat and moisture relations in air are briefly outlined.

The determination of moisture in wheat and wheat products, J. E. ANDERSON (*Northwest. Miller*, 184 (1935), No. 2, Sect. 2, pp. 25, 28).—The author of this contribution from the Kansas State College outlines the special features and the difficulties of moisture determination, and reports that "to overcome the slow rate of heating the samples and the nonuniformity of heating, a steam radiator was constructed and placed inside the vacuum chamber. The radiator was constructed of flat sections which served as shelves on which the samples were placed. The steam was supplied from an electrically heated boiler in which the temperature was regulated by pressure-operated control switch. It was found that with the use of the steam shelves all samples were heated at a uniform rate, and that only 10 minutes' time was required to heat the samples to the temperature of the oven. It was also found that 4 to 6 hr. were required to dry to constant weight, and that duplicate samples agreed within 0.05 percent. The procedure prescribed by the Official method was followed in leaving the lids on the dishes when placed in the oven. . . .

"The determinations as often made with the ordinary vacuum oven and procedure are not sufficiently accurate to be considered a standard with which other methods may be compared. Results which have been obtained by our modified method show a better correlation between the electrical determination and the vacuum-oven moisture determinations. It appears that the electrical method has been criticized because of a faulty operation of the vacuum oven."

Some observations on methods of ashing cereal products, L. H. BAILEY (*Cereal Chem.*, 14 (1937), No. 1, pp. 120-128).—At the U. S. D. A. Bureau of Chemistry and Soils, the author has prepared a review of previous work; and has compared the use of the nitrates of lanthanum, cerium, thorium, and yttrium with the supplementary use of alcohol and glycerine, with the magnesium acetate method, and with the A. O. A. C. method.

"The method found most satisfactory was a modification of the magnesium acetate method. When 3 g of flour (either wheat or rye) is moistened with 3 cc of an alcoholic solution of magnesium acetate equivalent to a blank of 5 mg MgO (6 g of the anhydrous salt per liter), and incinerated in a muffle furnace at 700° C., a white fluffy ash is obtained in approximately $\frac{3}{4}$ hr. In the case of bran, using a 2-g sample, 3 times the amount of magnesium acetate solution must be used and ashing continued for 1½ hr. The results duplicate those of the official A. O. A. C. method."

Detection of sulfur dioxide in flour, L. REIMERS (*Cereal Chem.*, 14 (1937), No. 1, pp. 129, 130).—When the presence of sulfur dioxide has been suspected in the preparation of the dough, to which it gives "a soft, inelastic character much resembling a slightly stiff cake batter", in order to confirm the presence of the impurity "slick the suspected sample alongside of a standard, which is known to be free from this gas, just as in the . . . slick test. Instead of using

water, dip the slick in a potassium iodide-starch solution. . . . This wetted slick is now passed carefully through air containing a light concentration of chlorine gas and the liberated iodine will give a light purple coloration to the slick. Care must be exercised not to overtreat with chlorine gas, as in such case too much iodine will be set free for the quantity of sulfur dioxide present. It should not be found difficult to secure a light coloration with proper care. Within a few minutes the sulfur dioxide, if present, will have diffused to the iodine and reduced it to the colorless iodide. The standard will remain colored, whereas the sulfur dioxide contaminated sample will fade out to a normal color. If sulfur dioxide was present, the contrast on the slick will be very marked."

The selenium and cystine content of some partial hydrolysis products of gluten from toxic wheat, D. B. JONES, M. J. HOEN, and C. E. F. GERSDORFF (*Cereal Chem.*, 14 (1937), No. 1, pp. 130-134).—In an investigation carried out at the U. S. D. A. Bureau of Chemistry and Soils, "gluten prepared from toxic wheat grown on seleniferous soil was digested for 3 hr. by pepsin. Four fractions of partial hydrolysis products of the protein were separated. Fraction A (2.5 g) was free from both selenium and cystine. Fraction C (1 g) was also devoid of selenium and contained only a trace of cystine. Fraction B (9 g), representing in weight 11.5 percent of the gluten used, contained 58 percent of the total selenium and 10.5 percent of the total cystine. By removing the dicarboxylic amino acids from Fraction B, the residual part of the fraction contained 1,178 p. p. m. selenium.

"The results show (a) that over half of the selenium in the toxic gluten can be concentrated in a small partial hydrolysis fraction, (b) an interesting relation in the distribution of selenium and cystine in the hydrolysis products. They also contribute further evidence that the selenium in toxic wheat is combined with the protein."

Quantitative determination of lactic acid in butter, H. C. TROY and P. F. SHARP ([*New York*] *Cornell Sta. Mem.* 202 (1937), pp. 17).—Three methods for the determination of lactic acid in butter were compared. These methods all depend on the oxidation of lactic acid to acetaldehyde, the removal of the acetaldehyde from the oxidation mixture, the collection of the acetaldehyde in sodium bisulfite solution, and the titration of the bound bisulfite with iodine, but differ in the amount of time required and the completeness of the removal of interfering substances.

Method 1, the Troy and Sharp extraction method (*E. S. R.*, 74, p. 5) is "accurate, sensitive, and reliable, but the extraction is tedious and time consuming." Method 2, the Whittier and Trimble direct-oxidation method (*E. S. R.*, 75, p. 396) is "the shortest and involves the fewest steps, but the results are somewhat uncertain and are not sufficiently reliable for detecting the small amounts of lactic acid which may be present in butter purported to be 'sweet-cream' butter. The oxidation-distillation procedure cannot be used when the butter is added to the oxidation flask."

Method 3 is the direct-precipitation method of Friedemann, Cotonio, and Shaffer (*E. S. R.*, 58, p. 114). In this method, "25 g of butter is added directly to the precipitation flask, and the precipitation with copper hydroxide is carried out as with any other milk product except that a correction is made for the volume occupied by the fat. This method is essentially as accurate as, and is much simpler and shorter than, the extraction method. It is nearly as short as the Whittier and Trimble method and is much more reliable. The filtrate may be oxidized by either the aeration or the distillation process. Method 3 is recommended."

The value of a lactic acid determination in the examination of butter is concisely indicated.

Factors influencing dill pickle fermentation, F. W. FABIAN (*Canner*, 84 (1937), No. 15, p. 16).—The author presents a very brief semipopular summary of some practical indications obtained in the work of the Michigan Experiment Station (E. S. R., 72, p. 157) on the commercial preparation of this product.

Checking fermentation temperatures, W. V. CRESS (*Wine Rev.*, 4 (1936), No. 4, p. 16).—The author of this note from the California Experiment Station calls attention to the inaccuracy of temperature readings taken by withdrawing liquid from the fermenting vat and taking its temperature with an ordinary short-stemmed mercury thermometer outside the vat. He found that readings as much as 5° F. too low were often obtained by this procedure. A dial-type, vapor-tension thermometer having a 6-ft. stem was tested and found to be satisfactory and to be obtainable at a reasonable cost. It is noted, however, that a 4-ft. stem would have been more convenient than one 6 ft. in length.

A method of storing experimental lots of fermented juices, W. V. CRESS (*Fruit Prod. Jour. and Amer. Vinegar Indus.*, 15 (1935), No. 3, p. 70).—To avoid the growth of film-forming fungi (E. S. R., 62, p. 504) after head space has been left by removal of samples, the author of this note from the California Experiment Station found the following procedure effective and much more convenient than repeated transfer of residues to smaller containers:

"A layer of neutral oil known as 'confectioner's slab oil' was placed in each jug of fruit wine, the layer being about 0.25 in. thick. As required for analysis, samples were pipetted from beneath the oil or were siphoned off by use of a bent glass tube and short piece of rubber tubing."

Tests on unfortified sweet wines, W. V. CRESS (*Wine Rev.*, 4 (1936), No. 2, pp. 20, 21, fig. 1).—This note from the California Experiment Station is a brief discussion of the preparation and the preservation, by pasteurization in sealed containers without the use of any sulfur dioxide, of sweetened wines of low alcoholic content. One of the methods for producing the required sweetness and lowered alcohol concentration was that of adding the sweet grape juice to a dry wine, the product being then bottled and pasteurized.

A note on the spoilage of Muscatel, W. V. CRESS (*Wines and Vines*, 17 (1936), No. 6, p. 6).—The author of this note reports an investigation at the University of California of an acid-forming spoilage organism which was widespread in the 1934 season. "Tourne" bacteria, at first suspected, could not be found; but wild yeasts of a marked acid-forming capacity were found to be very generally distributed on Muscats from the Fresno district.

With respect to the prevention of spoilage by such organisms, the author notes that "our tests show that high temperatures during fermentation favors the wild yeast activity and as is well known discourages the true wine yeast. If this form of spoilage again makes its appearance winemakers can readily prevent the growth of the wild yeasts responsible for it by the use of a moderate dose of metabisulfite or SO_2 ." As little as 75 p. p. m. of sulfur dioxide completely inhibited the wild yeasts; and this was also a concentration sufficient to check the lactic acid-producing Tourne bacteria. Pasteurization for control of Tourne is regarded as a little uncertain, but sterilizing filtration has been successfully applied in one large winery. The author points out the need for special care to avoid reinfection in sterilizing by filtration.

Western hemlock bark, an important potential tanning material, C. C. Smoor and R. W. Frey (*U. S. Dept. Agr., Tech. Bul.* 566 (1937), pp. 48, pls. 2, figs. 5).—The authors discuss the technical and economic possibilities of tannin extract prepared from bark now mostly dealt with only as a waste. On the basis of the moisture-free bark, the tannin content of this potential source is somewhat more than 15 percent, but the bark as removed in present practice contains too high a proportion of the wood, which contains little

tannin. Details of plant requirement, costs of raw material and operation, etc., are discussed, and it is concluded, in part, that under present conditions "successful utilization of the bark hinges on a rather narrow working margin of profit. A careful balance must be struck whereby sufficiently attractive prices can be offered for the bark without, however, imposing upon the extract a selling price that is prohibitive. Quick returns and large profits are not to be expected. On the other hand, in view of the tremendous quantities of bark and our large annual consumption of tannin in the making of a basic national commodity, namely, leather, there appears to be an opportunity of establishing a permanent business of large volume."

AGRICULTURAL METEOROLOGY

Moisture and farming in South Africa, W. R. THOMPSON ([Johannesburg]: Cent. News Agency, Ltd., 1936, pp. 260. [pls.] 34).—This book makes it plain that moisture is unquestionably and in a very special sense the dominant factor in agricultural production in South Africa. "This is particularly true of the crop farmer in the summer rainfall area, who, because of his system of farming and the inefficacy of the rainfall, is very liable to suffer the effects of common droughts."

On the basis of a wealth of data accumulated during many years by the author and others, the book deals at some length with the alleged drying-up of South Africa and the amelioration of the drought problem with special reference to the Schwarz-Kalahari scheme (E. S. R., 44, p. 208).¹ It is stated that "the Schwarz-Kalahari scheme is fantastic and appeals particularly to the layman. In responsible scientific circles it receives no support. . . . It should be viewed solely from the irrigational and not from the climatic standpoint." The author also considers at some length historic evidence in connection with the alleged drying-up of South Africa, holding that "the struggle of the farmer against droughts and an unsatisfactory water supply would appear to be common during the historic period, and is no new disability to farming."

Other chapters of the book deal with secular variations and agricultural aspects of South African rainfall; rainfall intensity with special reference to major trends; rainfall, soil erosion, and run-off; the role of evaporation in the dissipation of moisture; moisture dissipation through transpiration; the role of percolation in the dissipation of moisture; and veld burning.

The author is convinced that secular variations in rainfall exercise a great influence upon the natural vegetation and other allied factors, and that the low level of the Union's rainfall during recent years is without doubt a factor of considerable significance in explaining the hardships endured by the South African farming community. "Rainfall intensity is probably more important in encouraging run-off and soil erosion under the present circumstances of a sparser plant cover in some parts. . . . Bare space and soil erosion go hand in hand." Unused veld was found to prevent run-off and soil erosion almost entirely on a 3.75-percent slope of soil. Kraal manure, when applied to maize, effected a considerable decrease in run-off, thus indicating the importance and effect of organic matter in run-off control. Rhodes grass, representing perennial planted grasses, was very effective in preventing run-off and soil erosion.

Generally speaking, evaporation appears to be the principal dissipating factor of rainfall in South Africa when transpiration is excluded. This is particularly

¹ So. African Jour. Sci., 20 (1923), No. 1, pp. 208-222.

true in the summer rainfall areas. Evaporation losses in summer are mainly influenced by the distribution and amount of precipitation. It varies from over 0.3 in. after heavy rains to considerably below 0.1 in. in respect of a cultivated (once annually) bare soil surface. . . .

"Maize grown under Pretoria conditions is responsible for the utilization of almost two-thirds of the moisture from rainfall where run-off and percolation are excluded. Translating the data to field conditions, it would seem that on a gentle slope roughly the losses due to transpiration, evaporation, run-off, and percolation are respectively 50 percent, 35 percent, 15 percent, and nil." It is stated that it is likely that losses through evaporation and run-off have increased, and that the percentage of moisture available for percolation has diminished, apart from a decreased rainfall in many cases during more recent years. The need for a comprehensive investigation in this field is emphasized.

Considering the question of veld burning from the ecological, hydrological, and veld managing aspects, the author concludes that "in practice it will be difficult, if not impossible, to abandon burning altogether as a necessary measure in veld management in many areas of the Union. It is strongly urged that in view of the serious moisture limitations in South Africa, veld burning should be practiced very cautiously and only in cases of absolute necessity; where possible it should be eliminated altogether."

Florida's frost problem, E. S. ELLISON (*Fla. State Hort. Soc. Proc.*, 49 (1936), pp. 84-91).—The essential features of this article have been noted from another source (E. S. R., 77, p. 12). It especially emphasizes the importance of frost forecasting and protection and the accumulation of local data and experience.

Weather review ([*Connecticut*] *Storrs Sta. Bul.* 214 (1937), pp. 23-27).—Data on temperature, precipitation, and length of growing season at Storrs during the 49 years 1888-1936 are summarized.

The mean annual temperature during that period was 47.4° F., the highest 100° June 3, 1921, the lowest -21° February 9, 1934. The greatest daily range was 51° May 6, 1931. The mean annual precipitation was 43.52 in., the greatest 46.51 in. in 1901, the least 30.99 in. in 1930. The longest period with no precipitation was 42 days, January 4 to February 14, 1919. The longest growing season was 190 days, the shortest 131 days. The average date of last killing frost in spring was May 3, first in autumn October 9. The prevailing direction of wind for the greater part of the year was northwest, during June and July southwest.

SOILS—FERTILIZERS

General trends of the Desert type of soil formation, C. C. NIKIFOROFF (*Soil Sci.*, 43 (1937), No. 2, pp. 105-131, pls. 3).—This analysis of the factors involved in desert pedogenesis is a contribution from the U. S. D. A. Bureau of Chemistry and Soils. It is largely based upon a study of the Mojave Desert and a part of the Colorado Desert.

"As a consequence of an extreme reduction of the constructive activity of the biosphere, the Desert type of soil formation is dominated by a direct influence of the climatic agencies. These, in turn, are dominated by the temperature, because of the restricted amount of rainfall, which reduces the constructive power of the meteoric moisture so far as the development of a normal soil profile is concerned." The Desert type of soil formation is predominantly thermogenic and abiotic.

"An evolution of the normal profile of the Desert soils is effected by an upward capillary movement of the underground moisture and by a concentration of the chemical decomposition of its mineral skeleton at some depth from the surface. The first process leads to the formation of the desert crusts at some distance from the soil surface, and the second is responsible for a development of the clay pan horizon. A cementation of the crust can be produced by different salts or compounds which may occur in the rising solutions, and the crusts are formed wherever the compounds capable of causing cementation are present in the solution. The clay pan formation in the Desert soils is a result of a hydrolytic decomposition in situ of certain minerals, mainly feldspars and hornblende, and of a subsequent dehydration of the products of hydrolysis. This process does not take place on the immediate surface in the desert environment but proceeds at some depth from the surface.

"The development of these two processes can coexist in any particular Desert soil, developing their relative intensity by the alternating waves according to the changes of the climatic seasons. Their products not infrequently overlap each other in the soil profile. In either case, a certain part of the surface soil remains practically unaffected by the corresponding developments. This section of the soil profile may be regarded as a passive, or dead, horizon, in which soil moisture undergoes rapid and easy vaporization by the desert heat. The compounds which may be brought up in the rising solutions and the accumulation of which indurates the crust do not enter the dead horizon and do not reach the surface of the soil because of vaporization of the solvent as soon as it reaches the lower limit of this zone. Because of a deficiency of moisture caused by rapid vaporization of the water which may be supplied by rainfall, hydrolytic activity does not develop in the dead horizon. The upper limit of an effective chemical decomposition of the mineral skeleton, however, seems to be somewhat closer to the surface than the upper limit of precipitation of the crust-cementing compounds. Moreover, a coexistence of the two processes apparently tends to reduce the depressing influence of the dead horizon and consequently to reduce its thickness. An average and normal thickness of the dead horizon of the Desert soils is not certain. In many instances it is mechanically reduced by wind erosion or by the destructive run-off, whereas in many other cases it is greatly enlarged by a deposition of fresh strata of drifts dropped by the same agencies after the crust or a clay pan was formed. Because of a mechanical modification, its thickness varies from just a few inches to considerably more than 10 ft. The average normal thickness, however, is not far from 1 or 1.5 ft."

[Soil Survey Reports, 1932 Series] (*U. S. Dept. Agr., Bur. Chem. and Soils [Soil Survey Rpts.], Ser. 1932. Nos. 14, pp. 52, pls. 2, figs. 4, map 1; 15, pp. 70, figs. 2, map 1; 16, pp. 40, figs. 2, map 1*).—The reports here noted were prepared with the respective cooperation of the California Experiment Station, the [New York] Cornell Station, and the University of Nebraska State Soil Survey.

No. 14. *Soil survey of the Lodi area, California*, S. W. Cosby and E. J. Carpenter.—The Lodi area occupies 333,440 acres in north-central California. The area has the three topographic features of foothill lands, broad valley plain, and delta lands. Drainage conditions are varied.

This report records 18 series inclusive of 25 types. Hanford sandy loam is the most extensive of the soils listed, with 15.3 percent of the area.

No. 15. *Soil survey of Rensselaer County, New York*, W. J. Latimer et al.—Rensselaer County, eastern New York State, possesses an area of 416,640 acres of low plateau lands. Drainage is effected through the Hudson River system.

The soils examined were found to consist of 31 series inclusive of 45 types,

with 11.1 percent rough stony land and rock outcrop, and 7.8 percent Nassau shale loam.

No. 16. *Soil survey of Rock County, Nebraska*, W. D. Lee et al.—Rock County lies in north-central Nebraska, occupying 638,720 acres of tablelands, prairie plains, and sand-hill lands. Drainage is provided, in part, by the Niobrara, Elkhorn, and Calamus Rivers and by a number of tributary creeks.

Valentine sand occupies 33.9 percent of the area surveyed, Cass loamy fine sand covers 8.3 percent, and dune sand 33.2 percent. In all, 18 series represented by 24 types were found. Of these soils 12 are classed as grain-farming soils, 7 as grazing, and 8 as hay-farming soils.

[*Soil Survey Reports, 1933 Series*] (*U. S. Dept. Agr., Bur. Chem. and Soils [Soil Survey Rpts.], Ser. 1933, Nos. 3, pp. 30, figs. 2, map 1; 4, pp. 36, figs. 2, map 1*).—These surveys were carried out with the respective cooperation of the Texas Experiment Station and the Nebraska State Soil Survey.

No. 3. *Soil survey of Cass County, Texas*, M. W. Beck et al.—Cass County consists of 608,640 acres in the northeastern corner of Texas. "The relief is that of an intricately and deeply cut plain, and the land ranges from gently rolling to very rolling." Drainage conditions are varied. "Practically all the soils developed from alluvium, which comprise nearly one-sixth of the total area of the county, are very low and flat, with poor or moderately good drainage." The upland soils are, in general, better drained.

The soils surveyed are here listed as 15 series, including 17 types. Kirvin fine sandy loam, of which nearly one-half is a stony phase, takes up 24.8 percent of the county, Ruston fine sandy loam 26.2, Bowie fine sandy loam 20.5, and Bibb fine sandy loam, none of which is under cultivation, forms 10.4 percent.

No. 4. *Soil survey of Greeley County, Nebraska*, S. R. Bacon et al.—Greeley County possesses an area of 365,440 acres in east-central Nebraska. "The area included in this county is part of a formerly nearly level or rolling plain, on which minor relief has been produced by stream erosion and wind action. . . . All the county is well drained except some of the lower-lying first bottoms, that are frequently inundated, and a few small basinlike depressions scattered over the nearly level tableland." Colby silt loam occupies 29.3 percent of the area surveyed, Holdrege silt loam 23.1, and dune sand (of no value for tillage) 10.6 percent.

Studies on soils of the rice area, M. B. STUBBS and J. F. REED (*Louisiana Sta., Rice Sta. Bien. Rpt. 1935-36, pp. 14-16*).—A brief general report is made on rice soil studies, including plant-food content, exchangeable bases, accumulation of soluble salts and alkalinity, suitable fertilizers, effects of arsenate residues, etc.

[*Soil chemistry and soil fertility researches by the New Jersey Stations*] (*New Jersey Sta. Rpt. 1936, pp. 97-102, 103, 104*).—These pages deal briefly with fertilizer and lime studies; phosphate adsorption and displacement; value of organic matter; base-exchange and lysimeter studies; soil microbiological complexes and methods of studying them; the mechanism of decomposition of organic matter in the soil and the processes contributing to the formation of soil "humus"; reciprocal influences of plants and micro-organisms of the soil; autotrophic bacteria, their physiology and role in soil processes; and marine bacteria and their role in the cycle of life in the sea.

[*Soil and erosion investigations of the Wisconsin Station*] (*Wisconsin Sta. Bul. 438 (1937), pp. 27-35, 87, 88, 88-93, 97, 98, figs. 7*).—A number of the station's soil investigations are summarized under the following captions: Factors affecting erosion measured by La Crosse Station, by O. E. Hays and V. J. Palmer; soil conditions determine success in growing forest nursery stock,

by S. A. Wilde, H. M. Galloway, and H. H. Hull; the use of the exposure meter in soil analysis, by Wilde; Marshfield trials show effects of fertilizer on farm crops, and lime and phosphate boost alfalfa yields on Colby and Marathon silt loam soils, both by F. L. Musbach; and improved procedure facilitates removal of colloids from soil samples, by E. Truog, J. R. Taylor, Jr., R. W. Pearson, and M. E. Weeks.

The "chemical analysis" of the soil, E. A. MITSCHERLICH (*Soil Sci.*, 43 (1937), No. 4, pp. 253-255).—The author discusses the present situation with regard to estimations of the liming and nutrient requirements of soils.

"For the nitrogen content, especially the nitrogen requirements, field experiments offer the best and most reliable information. For the lime requirements of the soil, a simple reaction determination is sufficient. The P and K requirements of the soil are difficult to determine for the following reasons: Field experiments are not sufficient because of the high activity factor of these nutrients, and the so-called chemical methods are not as yet efficient. In field experiments it often happens that during the season of fertilizer additions no increase in yield takes place; but if no additions of nutrients were made, the yield would drop the following year. It often happens that the quantity of nutrients in the soil is sufficient to produce a maximum crop the year of the experiment. The nutrients may, however, be exhausted the year following. In laboratory experiments we fail to bring into solution those elements which might be utilized by the next year's crop. If we were able to bring these nutrients into solution such analyses would present no difficulties.

"Field experiments are the standard. Soil analyses are important for the evaluation of cultivated land, and they are important for the farmer who is looking for advice about fertilizers. The field experiment, however, as pointed out, fails under certain conditions. To obtain reliable results, it is necessary to decrease the nutrient content of the soil to a very low level. This may be accomplished either by using a shallow layer of soil, thus decreasing the quantity of soil which actually supplies the nutrients to the plants, or by 'diluting' the soil with sand, free of nutrients."

Summarizing his analysis of the soil-testing problem, the author concludes: "The question may be asked, Why do we need chemical or laboratory methods and why should we not limit ourselves to pot experiments? The answer is that in the case of pot experiments the time element is a factor which causes excessive expense. Also, it is necessary to test countless numbers of soils, which necessitates a cheaper and more rapid method. . . .

"It is hoped that the International researches will furnish reliable results in perhaps 80 percent of all cases. . . . Applying laboratory methods it would be possible to investigate in Eastern Prussia 10,000 soils annually, instead of the 2,000 which now are examined, involving the use of 20,000 culture vessels. Thereby the cost of the investigation would be considerably lowered, to the ultimate benefit of agriculture."

On the mobility of exchangeable cations in the soil, S. S. JARUSOV (*Soil Sci.*, 43 (1937), No. 4, pp. 285-303).—The author finds in part that:

"The mobility of exchangeable cations depends upon the physicochemical properties of the adsorbents and their structural characteristics, determining the strength of the bond uniting the cations and participating in the exchange with the complex. This mobility also depends upon the degree of saturation of the complex by the cation in question. In soils completely saturated by one cation, the mobility of exchangeable cations varies two- to threefold in dependence upon the properties of the soil. The highest mobility is shown by exchangeable cations in red soils; the lowest, in chernozem. As we proceed down

the soil horizons in the chernozem and podzolized zones, the mobility of the cations increases, as a rule.

"The unequal mobility of exchangeable cations in different soils seems to be due to differences in structure of the ion atmosphere of colloids in these soils. Only that part of the exchangeable cations (the proportions being different in different soils) which composes the looser, external part of the ionic atmosphere participates essentially in the exchange reactions.

"In the case of two cations present in a varying proportion in the complex of one soil and possessing different energies of absorption, the strength of the bond of one of them with the complex (the one with a higher energy of absorption) decreases with the increase of the saturation of the complex by it, and its mobility increases. The mobility of the cation of lower absorption energy changes relatively little with the increase of the saturation of the complex by it. The mobility of exchangeable cations depends not only on the kind of soil and on the degree of saturation of the complex by them, but also on the kind of the exchangeable cations accompanying them in the soil. . . .

"It is evident from the above that the strength of the bond and the mobility of exchangeable cations possess an actual significance for the solution of a number of problems of agronomy, such as the physical properties of soil, the availability of exchangeable cations to the plants, the availability of soil moisture to the plants, the interaction between soils and fertilizers, and the effectiveness of fertilizers."

Studies in the electrodialysis of soils.—I, **Electrodialysis by the rotating electrode**, AMAR NATH PURI and R. C. HOON (*Soil Sci.*, 33 (1937), No. 4, pp. 305–309, fig. 1).—The authors describe and illustrate by a diagram an apparatus in which the cathode consists of a perforated copper cone resting in a glass funnel; the anode, of a cone of gold or platinum wire gauze rotated at from 200 to 300 r. p. m. The diaphragm consists of a cone of a suitable filter paper resting in the cathode cone in the funnel.

"Electrodialysis, as revealed by the percentage recovery of exchangeable bases, is quicker with the rotating electrode than with the stationary one. Different exchangeable bases take varying lengths of time for displacement by the same current density. The order of their ease of displacement is $\text{Na} > \text{K} > \text{Ca} > \text{Mg}$. There is very slight recovery of Mg, and it is doubtful if the total content could be recovered by electrodialysis within a reasonable time. The volume of the electrodialysate is slightly greater, and the maximum temperature of the anode chamber, slightly higher in the case of the stationary electrode than in the case of the rotating one. Currents as high as 0.5 a can be passed, using the rotating electrode, without too much heating resulting. With this current exchangeable bases can be recovered in less than an hour. The advantages of a rotating anode are greatly minimized when the size of the anode is large. . . .

"The arrangement of apparatus suggested . . . is simple and cheap. A number of electrodes could be run with the same motor. It is, however, necessary that each cell should have a separate rheostat to adjust the current, which can be kept at approximately 0.5 a. Electrodialysis has limited value as a means of determining exchangeable bases, especially in the case of replaceable Mg; but the rotating electrode is a distinct improvement over the stationary one in regard to rapidity of displacement."

Replaceable base determination by electromigration, H. H. KING, M. J. CALDWELL, and A. T. PERKINS (*Soil Sci.*, 43 (1937), No. 4, pp. 311–316, figs. 3).—The authors of this contribution from the Kansas Experiment Station report in part that "results obtained by the various methods indicate that all will give

comparable values for calcium and magnesium. There has appeared no reason in this investigation why the monovalent cations would act differently from those studied. It is probable that the reported discrepancy in the monovalent to divalent base ratios obtained by the electromigration and other methods should be sought in the proper application of the agar blank, since the agar is comparatively rich in the monovalent ions.

"The electromigration method appears to the authors to be more complicated and subject to more variables and difficulties than a leaching process and, while capable of giving similar results, appears to have little decided advantage over a less elaborate system of replaceable base determination."

A method of measuring the capillary tension of soil moisture over a wide moisture range. R. GARDNER (*Soil Sci.*, 43 (1937), No. 4, pp. 277-283, figs. 2).—The method proposed in this contribution from the Colorado Experiment Station consists in determining a capillary tension curve for a grade of filter paper and then indirectly determining the tension curve for soils by placing them in contact with the paper at various moisture concentrations.

"Results show that capillary tension curves for soils may be determined by this method with sufficient precision to show the characteristic textural differences between soil types, and may serve as a measure of moisture-storing capacity."

Heat of wetting of some soil colloids at different moisture contents. M. HOSEH (*Soil Sci.*, 43 (1937), No. 4, pp. 257-275, pl. 1, figs. 4).—From experiments carried out at the University of California, the author concludes in part that "in heating the soil colloid the amount of water removed depends, other conditions being equal, on the temperature of heating; the history of drying is unimportant. Drying at 110° C. does not remove all of the water found on the surface of the soil colloidal particle. The higher the temperature of heating over the range investigated, i. e., the more energy that is applied, the more water there is removed. The more water that is removed from the soil colloidal particle, the greater is the force with which the particle will attract water, provided it is not rendered inactive. These two forces are proportional, and there is reason to believe that they are equal and opposite. Heat of wetting will be evolved as long as the internal structure of the soil colloidal particle remains unaltered; in this experiment this alteration set in when the colloids were heated above 400°. When the nature of the colloidal particle becomes destroyed, as by sintering, there will be no heat evolved on wetting. A soil colloidal particle may lose water upon heating even beyond the temperature at which there is no heat of wetting."

Chemical nature of organic matter or humus in soils, peat bogs, and composts. S. A. WAKSMAN (*Jour. Chem. Ed.*, 12 (1935), No. 11, pp. 511-519).—In a semipopular paper, contributed from the New Jersey Experiment Stations, the author takes up the topics characteristics of humus, decomposition of plant residues and formation of humus, chemical nature of humus, and humus and plant nutrition. The following classification of the various types of humus forms a basis of a part of the discussion: "(A) Humus types formed by decomposition of plant and animal residues under aerobic, or only partly anaerobic, conditions in composts and in soil: (1) Humus of composts—stable manures, composts of plant residues with or without addition of inorganic salts ('artificial manures') [and] (2) humus in soil—(a) plant residues decomposed under conditions of high acidity or low temperature or both (raw humus in forest soils and in heath soils, alpine humus) [and] (b) plant residues decomposed under less acid, neutral, or alkaline conditions (typical soil humus). (B) Humus types formed by decomposition of plant and animal residues under

anaerobic conditions: (1) Recent formations—high moor, low moor, and sedimentary peats [and] (2) old formations—soft (brown coals, lignites) and hard coals (anthracites). (O) Humus types formed in water basins: (1) Recent formations—water-soluble humus and humus in lake and sea bottoms [and] (2) geologic formations—source beds of petroleum.”

Ionic relationships in peat, B. D. WILSON and E. V. STAKER (*Soil Sci.*, 43 (1937), No. 4, pp. 247–252).—At the [New York] Cornell Experiment Station, in an investigation of the electrodialysis of peats varying widely in percentage of saturation with bases and in other chemical characteristics, the ions normally functioning as cations were found in the anode compartment of the Mattson cell (E. S. R., 56, p. 115), and ions normally functioning as anions were found in the cathode compartment.

“Ions of this character were found to be intimately associated with the organic matter of the diffusates. The results of the investigation suggest that these ions were transported to the respective poles as integral parts of organic matter rather than as adsorbed particles on the surfaces of organic matter. Most of the exchangeable cations of the peats were found to have been present in the peats as ions of organic salts. Practically all of the sulfur was found to be a component of the organic matter, whereas most of the phosphorus appeared to be in the form of phosphate ions.”

The production of macroscopic colonies on plaques of soil, J. K. WILSON (*Jour. Amer. Soc. Agron.*, 29 (1937), No. 4, pp. 286–292).—This contribution from the [New York] Cornell Experiment Station records the results of a study of 366 samples of soil with respect to the production of macroscopic colonies on soil plaques. It is concluded that “if the proper nutritional condition is effected by soil amendments of one sort or another, macroscopic colonies will develop from the flora naturally present in the soil. Some salts appeared to be more effective in this respect than others. $MgNH_4PO_4$ came nearest to universal efficiency. When other salts commonly employed in such work failed to effect colony growth this salt was effective.”

The author further shows that “the response or lack of response of the microflora of the soil to the various salts that were employed in the plaques provide no direct forecast of which nutrients should be applied, if any, to a particular soil in order that it may grow field crops successfully. The favorable effect of $CaCO_3$ and of K_2HPO_4 on the development of macroscopic colonies when these materials are applied to soils that possess low pH values suggests that such soils may be deficient in these components, but since such compounds may depress colony growth, . . . [or have] no visible effect at all, it is suggested that more information concerning the factors that favor colony development is necessary before the plaque method can be of much service in forecasting the deficiencies of the soils of New York for specific nutrients.”

The availability of the principal nutrients in a soil during the crop-growth period, R. J. BORDEN (*Hawaii. Planters' Rec. [Hawaii. Sugar Planters' Sta.]*, 41 (1937), No. 1, pp. 47–55, figs. 5).—The author notes that it has been customary in determining available nutrients in cultivated soils to sample either before planting or after harvesting. He considers that frequent samples taken during the growth of the crop yield information not obtained in the more usual procedure, and offers tabulated and graphically represented results of semimonthly determinations of available nitrogen, potassium, and phosphate carried through the entire growth period of a cane crop in support of the view expressed.

Carbon dioxide production in mannitol-treated soils as a measure of crop response to soil treatments, W. B. ANDREWS (*Jour. Amer. Soc. Agron.*,

29 (1937), No. 4, pp. 253-268, fig. 1).—The author of this contribution from the Michigan Experiment Station reports upon a new procedure for studying the relation between crop response and response of micro-organisms to soil treatments and to varying fertility levels. The production of CO_2 is used as a measure of the response of micro-organisms, the procedure consisting in treating soil with mannitol and determining the CO_2 at the end of 24 hr. The following specific results of the experiments with the method are stated:

"The production of CO_2 in soils to which mannitol had been added under controlled laboratory conditions tended to furnish a basis for measuring the nitrogen and phosphorus requirements of soils for cotton. There was a rather high correlation between the response of cotton to lime, phosphorus, and phosphorus and nitrogen and the production of CO_2 by mannitol-treated soils. Potassium, however, did not increase CO_2 production even where potassium gave increases in crop yields. Micro-organisms (CO_2 production) responded to lime and superphosphate only when nitrogen was added. Air drying increased the production of CO_2 on rewetting by some soils, but the results were not consistent. On soils which were deficient in CaCO_3 , the substitution of MgCO_3 for part of the added CaCO_3 did not consistently increase the production of CO_2 . Calcium arsenate had no effect on CO_2 production when used in large or small amounts, but intermediate quantities reduced it. Superphosphate did not intensify arsenic toxicity to soil micro-organisms, nor did FeSO_4 alleviate the harmful effects of arsenic as measured by CO_2 production. This is contrary to crop response. Soils deficient in copper, manganese, and zinc, as indicated by plant growth, showed no deficiency of these elements by this method."

Evaluation of nitrogen in molasses, R. J. BORDEN (*Hawaii. Planters' Rec. [Hawaii. Sugar Planters' Sta.]*, 41 (1937), No. 1, pp. 19-24, fig. 1).—The author reports trials of the effect of molasses on the productivity of a porous, sandy loam soil of pH 5.8. The soil showed a nitrogen availability of 53 lb. per acre-foot and a total nitrogen content of somewhat more than 5,000 lb. per acre-foot.

The application of molasses to this soil depressed crop yields, and there was little evidence to indicate that the nitrogen content of the molasses became available.

Blast-furnace processes for the production of phosphatic and potassic fertilizer materials, P. H. ROYSTER, K. G. CLARK, T. P. HIGNETT, L. E. BOWE, H. I. LANSDON, J. C. SOUTHAARD, and J. W. TURRENTINE (*U. S. Dept. Agr., Tech. Bul.* 548 (1937), pp. 75, figs. 22).—The authors report on phosphate, potash, and combined phosphate-potash smelting experiments carried out on a semicommercial scale by the Bureau of Chemistry and Soils from 1927 to 1933.

In the phosphate smelting process the heat requirement closely approximated that needed in the reaction indicated by the following equation:

"Only heat at or above $2,255^\circ \text{F}$. is available for carrying out the phosphate-reduction reaction. The amount of phosphate reduced is limited by the heat available above this temperature. Within the limits 0.82 to 1.12, the base-acid ratio of the charge, $\frac{\text{CaO} + \text{MgO}}{\text{Al}_2\text{O}_3 + \text{SiO}_2}$, was not found to affect appreciably either the heat required by or the efficiency of the reduction process.

"Phosphate smelting is technically feasible with low or medium blast temperatures but is commercially practicable for fertilizer production only if high blast temperatures are available."

The results of the potash smelting experiments showed that: "The heat involved in potash-volatilization reactions occurring in the blast furnace was too small to be detected. The principal heat requirements of potash smelting are, therefore, the heat required to slag the charge, to decompose the blast moisture, and to satisfy the heat losses. Volatilization to the extent of 90 percent was not realized from charges having a base-acid ratio, $\frac{\text{CaO} + \text{MgO}}{\text{Al}_2\text{O}_3 + \text{SiO}_2}$, less than 0.9. The addition of calcium chloride increased the volatilization of potash from charges having low base-acid ratios. This effect was less pronounced for charges having base-acid ratios as great as 0.9.

"Potash smelting is a technically feasible process but is commercially practicable only if low-cost limestone and fuel are obtainable."

The results of the combined potash-phosphate smelting experiments showed that: "The combined smelting of potash and phosphate offers no technical difficulties not met in the two separate processes.

"Combined smelting is commercially more attractive than the smelting of the same amounts of potash and phosphate independently because it requires less fuel and flux and yields a more easily transported product.

"It must be emphasized that methods for recovering the products in all three processes require further investigation. It should also be pointed out that the indicated possibilities in these processes, especially in the phosphate and potash-phosphate processes, depend largely upon the development and application of stoves capable of economically producing blast temperatures several hundred degrees higher than in present iron blast-furnace practice. It is expected that the stoves used in this investigation will point the way to such a development. In potash smelting the exact amount of calcium chloride required is uncertain, the consumption of carbon by some unknown reduction reaction is unexplained, and the full benefit of using burned lime as a flux is undetermined. These factors, as well as the applicability of carbonized Wyoming coal as a blast-furnace fuel, remain to be investigated."

Availability of phosphate rocks in soils of varying degrees of acidity. R. P. BARTHOLOMEW (*Jour. Amer. Soc. Agron.*, 29 (1937), No. 4, pp. 293-298).—At the Arkansas Experiment Station, the author was unable to show that soils of ordinary degrees of acidity cause an increase in the availability of rock phosphates. "It appears evident from the results of the growth studies and from the amount of phosphorus absorbed by the plants that it is only in extremely acid soils that the acidity of the soil may increase the relative availability of the phosphorus in phosphate rocks. Furthermore, from the results presented, rock phosphate cannot be recommended indiscriminately as a fertilizer on acid soils similar to those used in these experiments, since the soil acids have not generally increased the amounts of phosphorus absorbed by plants." With regard to fluorine content, the author finds that "if the results under each degree of acidity are examined, it will be noted that regardless of the degree of acidity there is a general trend for the availability of the phosphorus in the phosphate rock to decrease as the percentage of fluorine in the rock increases."

The effect of carbon dioxide on soil reaction and on the solubility of phosphorus in soils. F. B. SMITH, P. E. BROWN, H. C. MILLAR, and H. L. BODLEY (*Soil Sci.*, 43 (1937), No. 2, pp. 93-104).—An investigation carried out at the Iowa Experiment Station has shown that the solubility of the soil phosphates contained in the soils examined (Carrington loam and Carrington and Tama silt loams) in 0.002 N sulfuric acid is increased by treatment of the soil either

with gaseous carbon dioxide or with a "carbonic acid" solution (water saturated with carbon dioxide, pH 4.2). It was also found, however, that "carbon dioxide or carbonic acid may result in a decreased H-ion concentration of the soil solution, depending upon the soil type. In the untreated Carrington silt loam carbon dioxide increased the H-ion concentration, but treatment with rock phosphate buffered the solution sufficiently so that there was no effect. The Tama silt loam was sufficiently well buffered without the rock phosphate addition to prevent the carbon dioxide producing an acid reaction. Rock phosphate and calcium carbonate in the Tama soil with carbon dioxide resulted in a decrease in H-ion concentration as compared with that of the soil treated with these materials but without the carbon dioxide. Since nitrate production was also stimulated in these soils by carbon dioxide, it would seem that the increase in pH was due to a hydrolysis of the ammonifiable and nitrifiable organic matter. The increased solubility of phosphorus in these cases is certainly not due to an increased H-ion concentration but may be explained on the basis of the production of more soluble forms of phosphorus coincident with the change in soil reaction. Thus, the net effect of carbonic acid or carbon dioxide is an increased solubility of the phosphorus, regardless of the effect of the carbon dioxide on soil reaction. This is further emphasized by the fact that the correlation between the pH of the soil and the phosphorus soluble in 0.002 N sulfuric acid was not significant."

Carbon dioxide was more effective in increasing the solubility of phosphorus in the untreated Carrington silt loam than was the carbonic acid, but the reverse relation was found in the untreated Tama silt loam. In the rock phosphate-treated soils the carbonic acid was more effective than carbon dioxide in the Carrington silt loam, but again the reverse relation was obtained in the Tama silt loam. "In other words treating the Carrington silt loam with rock phosphate caused it to react to carbonic acid in the same way as the untreated Tama silt loam. This treatment also caused the same directional change in pH of the two soils. This does not seem to be an important point, but it serves to emphasize the fact that carbon dioxide may have different effects in different soils and also that the forms of phosphorus in the two soils may be very different.

"The results obtained with 0.002 N sulfuric acid as the extractant of the phosphorus are perhaps different from those that would have been obtained with any other extractant. However, the fact that carbonic acid or carbon dioxide increased the solubility of the soil phosphorus in this relatively strongly acid solution would seem more significant than if similar results had been obtained with a less acid solution as the extractant."

Rare elements in German brown-coal ashes, W. FUCHS (*Indus. and Engin. Chem.*, 27 (1935), No. 9, pp. 1099, 1100).—The author reports from the New Jersey Experiment Stations that "a certain favorable effect on plant growth could be traced back to the water-soluble substances in the coal, possibly the rare elements." Of 45 elements sought in the analysis of brown-coal ash, 25 were found in quantities ranging from 35.6 percent (calcium) and 10.7 percent (iron) to 10⁻⁶ percent or less.

Registration, labeling, and inspection of commercial fertilizers, 1936, F. B. MUMFORD, L. D. HAIGH, and E. W. COWAN (*Missouri Sta. Bul.* 581 (1937), pp. 43).—The usual analytical data, and related information concerning the 1936 fertilizer inspection, are brought together in this bulletin.

Analyses of commercial fertilizers and ground bone; analyses of agricultural lime, 1936, C. S. CATHCART (*New Jersey Sta. Bul.* 622 (1937),

pp. 15).—The analytical data here recorded concern the composition of fertilizers and fertilizer materials registered after March 13, 1936 (E. S. R., 77, p. 25). The bulletin contains also a discussion of the inspection as a whole, together with statistical and other pertinent information.

AGRICULTURAL BOTANY

Protoplasm, W. SEIFRIZ (*New York and London: McGraw-Hill Book Co., 1936, pp. X+584, figs. 179*).—The author has endeavored to bring together all those parts of the branches of science which bear on the physical chemistry of living matter. So far as consistent with accuracy and completeness the presentation is nontechnical, and the text is subdivided under the following subjects: The living substance, the cell, model making, micrurgy, tissue culture, the colloidal state, emulsions, hydrophilic sols and gels, surface tension, adsorption, osmosis, imbibition, viscosity, elasticity, the structure of protoplasm and organic colloidal matter, permeability, acidity, electrophysiology, electrokinetics, radiant energy, the role of water, salts, carbohydrates, fats, proteins, regulatory substances, and the origin of living matter.

A topical bibliography of over 23 pages and a combined author and subject index are provided.

A recording potentiometer for use in physiological investigations, R. H. WALLACE (*Plant Physiol.*, 12 (1937), No. 2, pp. 487-498, figs. 7).—As ordinarily adjusted the instrument described and illustrated in this contribution by the Connecticut State College is activated by 0.1 μ a (i. e., 0.1 mv), and higher or lower sensitivity can be obtained. Fundamentally, it is a self-balancing Wheatstone bridge of the null-indicator type. The universal bridge can be adjusted to get any millivoltage from 3 to the full value of the battery. Calibration is made with the usual potentiometer. The drum, which is 36 cm in circumference, can be made to turn once a minute, once an hour, or twice a day. The complete instrument can be readily built, and no fundamental element of the one described has been replaced in a year of continuous use. The operation and application of the apparatus are described in some detail.

[**Work in plant physiology by the New Jersey Stations**] (*New Jersey Stas. Rpt. 1936, pp. 73-84*).—Reports of progress are given on boron and manganese deficiency (including the adequacy of the boron and manganese content of natural nitrate of soda to support plant growth in sand culture, morphological studies of boron-deficient plants, microchemical study of the effects of boron deficiency, the effect of boron deficiency in cotton upon absorption rates of potassium and nitrogen, and microchemical analysis of boron-deficient cotton plants); investigation of the relation of H-ion concentration of plant tissues to iron availability and distribution in plants (corn used); effect of aeration on the growth of oat plants in solution cultures; nutrition studies with corn; the growth of beets in sand culture with different levels of potassium supply; and the effect of nutrient salt concentration upon the growth of the snapdragon plant.

Studies on wheat grown under constant conditions: A monograph on growth, H. L. VAN DE SANDE-BAKHUYZEN (*Stanford University, Calif.: Food Res. Inst., 1937, pp. XVI+400, figs. 27*).—This monographic study, the results of which are addressed mainly to the specialist, was undertaken primarily to determine the physiological bases for correlations of growth and yields with environal factors such as temperature, radiation, rainfall, fertilization, etc. The seven main parts deal, respectively, with the growth curve in annual plants, methods and materials used in the investigation, general growth fea-

tures, dry weight and moisture content of the different organs, dry weight and moisture of the "standard" plant, nitrogen and carbon of the organs, and nitrogen metabolism in relation to growth and development.

This volume also contains contributions on the carbon and nitrogen content of the wheat plant, by E. P. Griffing and C. L. Alsberg.

Devernalization of winter rye by high temperature, F. G. GREGORY and O. N. PUEVIS (*Nature [London]*, 138 (1936), No. 3502, pp. 1013, 1014, fig. 1).—The results of tests in which imbibed seeds were held in air and in nitrogen at various temperatures and for various periods of time indicated that high temperature negates the effect of low temperature progressively as the relative period of high temperature is increased, and that this effect is not due directly to the anaerobic condition. It is stated that the check to growth is not the potent factor in vernalization, but that the effect must be attributed to the low temperature.

The vascular anatomy of *Helianthus annuus* L., J. H. PRIESTLEY and L. I. SCOTT (*Leeds Phil. and Lit. Soc. Proc.*, 3 (1936), No. 3, pp. 159–173, pl. 1, figs. 3).—"Recent work on tree growth has shown a close relation between extension and radial growth. The anatomy of *Helianthus* is analyzed from this point of view. . . . Cambial activity commences at the leaf insertion, as this is a position of minimum extension. Subsequently it spreads both up and down but its special feature is the unlimited propagation downwards. The uniformity of vessel counts at different levels down a leaf trace bundle is discussed as evidence for simultaneity of vessel expansion over considerable distances. Protophloem strands develop basifugally and form an anastomosing system. Possibly these are associated with the movement of food, derived from adult leaves up towards levels where young primordia are growing."

A note upon summer wood production in the tree, J. H. PRIESTLEY and L. I. SCOTT (*Leeds Phil. and Lit. Soc. Proc.*, 3 (1936), No. 4, pp. 235–243, pl. 1).—"Recent studies have shown that the earlier spring wood formation is initiated by the vascular differentiation in the leaves of the extending shoot and from thence extends basipetally throughout the tree. The point is now examined as to whether the later formed wood has a similar connection with growth activities proceeding at the apex." It is concluded that "summer wood is . . . necessarily late formed, but the extent to which it takes on the characteristics usually associated with summer wood depends at any point in its basipetal course of development upon the conditions of water and food supply in the surrounding tissues at the moment of its differentiation at this point."

Sap ascent in the tree, J. H. PRIESTLEY (*Sci. Prog. [London]*, 30 (1935), No. 117, pp. 42–56, fig. 1).—The author first presents some criticisms of the cohesion theory of sap ascent and then reviews recent studies (especially his own) on vessel differentiation and water movement into the bud. His "main thesis has been twofold: (1) That the cohesion hypothesis does not rest upon a satisfactory experimental basis, and that (2) the movement of water into the expanding leaves in spring is associated with processes of growth and differentiation both in leaf and woody axis which are entirely neglected at present in the orthodox treatment of the problems of sap ascent."

The pollen production of anemophilous plants: A comparative investigation with reference to the pollination process in animal pollinated plants and pollen-analytical forest history studies. (Investigations of the morphology and biology of pollen, VI.) [trans. title], F. POHL (*Bot. Gentbl., Beihefte*, 56 (1937), Abt. A, No. 2–3, pp. 365–470, figs. 7).—Continuing this series of studies (E. S. R., 66, p. 319), this monograph deals with the quantitative pollen yield of wind- v. animal-pollinated plants, and with the amount of pollen

produced in relation to the number of ovules to be fertilized. The study included 39 species, predominantly of wind-pollinated plants. There is a bibliography of 80 references.

The continuous measurement of photosynthesis, respiration, and transpiration of alfalfa and wheat growing under field conditions, M. D. THOMAS and G. R. HILL (*Plant Physiol.*, 12 (1937), No. 2, pp. 285-307, figs. 10).—The authors describe and illustrate apparatus designed to measure continuously and automatically the CO_2 exchange and transpiration of plants in situ. By its use the CO_2 exchange of two similar plats of alfalfa was measured simultaneously and continuously for 26 days, and the hourly values of respiration and photosynthesis were plotted. Data summarizing the daily apparent assimilation values of a wheat plat from the boot to the dough stages are also presented.

The alfalfa curves indicate that the two plats gave closely concordant respiratory and photosynthetic responses to the environment. Statistical analyses of the curves indicate the value of the apparatus for measuring very small effects of an experimental treatment. The influence of clouds on the photosynthetic rate was strikingly shown by the curves, and the data obtained indicate the rate in alfalfa to be a linear function of the sunlight intensity up to about 52 percent of the normal maximum at Logan, Utah. Greater intensities did not increase the rate appreciably. Respiration varied with the temperature, increasing about fourfold in rate between 0° and 20° C. Only 16.5 percent of the CO_2 assimilated could be accounted for as top growth, the remainder probably being stored in the roots.

The wheat data indicated that the assimilatory rate reaches a maximum in the flowering stage and then falls off in the milk and dough stages owing to senescence. The top growth accounted for 83.3 percent of the net assimilation.

The transpiration curves resembled the CO_2 exchange curves in shape, but were more pointed and also definitely skew in the daytime. The transpiration curves evidently reflected the temperature changes closely, whereas photosynthesis followed more nearly the light intensity. The average deviation of the transpiration values for the two alfalfa plats was less than 5 percent.

Induced changes in respiration rates and time relations in the changes in internal factors, L. P. MILLER, J. D. GUTHRIE, and F. E. DENNY (*Contrib. Boyce Thompson Inst.*, 8 (1936), No. 1, pp. 41-61, figs. 5).—Treatments of potato tubers with vapors of various chemicals which increased the CO_2 output also usually induced large increases in the sugar content, but these increases did not occur until after the peak of the higher respiratory activity had passed. During the period of rapid rise in CO_2 output the sugar content remained unchanged or decreased. Ethyl alcohol, which decreased the CO_2 output, had little effect on the sugar content or induced decreases. Catalase and peroxidase activity also were not directly connected with CO_2 output changes. Chemicals which increased respiration induced large increases in the activity of these enzymes, but these changes tended to follow rather than precede or coincide with changes in CO_2 output. With ethyl mercaptan this enzyme activity was depressed much below the control while the rise in CO_2 output was taking place and during its peak, and it was only later, when the respiratory rate was decreasing, that these enzymes were more active in the treated than in the control tubers. Ethyl alcohol, which decreased respiration, increased catalase activity and decreased peroxidase activity.

The increase in methylene blue reducing capacity of the juice that follows ethylene chlorhydrin or butyl halide treatments is not the cause of the increased respiration induced by these treatments, since the increase in reducing

capacity occurred later than the increase in respiration. The decrease in citric acid and increase in pH began at about the same time as the increase in respiration, there being a correlation among these three changes. These results support the view that citric acid is converted into CO_2 in the rapidly respiring tissue and that the pH increases from the decrease in citric acid. Citric acid is probably the source of a large part of the CO_2 produced by the treated tissue. The large increase in glutathione following treatment with ethylene chlorhydrin is not the cause of the increased respiration, since it took place 40–60 hr. after the beginning of treatment and much later than the increase in respiration. Butyl halides, which induce large increases in respiration, decrease the glutathione content, possibly by some direct action on glutathione. The decrease in sulfate following treatment with ethylene chlorhydrin probably occurs about the same time as the increase in glutathione and may thus be due to utilization of sulfate in the glutathione synthesis.

Time course of photosynthesis for a higher plant, E. D. McALISTER (*Smithsn. Misc. Collect.*, 95 (1937), No. 24, pp. 17, pls. 2, figs. 10).—The author describes and illustrates a new spectrographic method of gas analysis which he has here applied to measurements of the CO_2 exchange between Marquis wheat and its environment, these being the first ever made on the time course of photosynthesis during the first few seconds after illumination of a higher plant.

Using this method, it was found that the induction period represents a certain amount of CO_2 lost to photosynthesis. This amount lost approaches zero progressively with decreasing intensities of illumination and is apparently approaching an asymptotic value at high light intensities. The induction period is prolonged to 12 or 15 min. after a night of darkness. The striking similarity of the present data with previous work on algae indicates a mechanism of CO_2 assimilation fundamentally alike. The importance of the induction period in elucidating photosynthesis is emphasized, since it is chemical in nature, sensitive to temperature, and is produced by light. Induction in intermittent illumination of equal light and dark periods is shown to be very small at high frequencies—one-sixtieth second length period—and is larger than normal for periods of 5–15 sec.

The immediate appearance of respiration at the termination of illumination with a rate equal to that before illumination, together with its independence of light intensity as here reported, led to the conclusion that light has no direct effect on respiration.

A minimum CO_2 assimilation in flashing light (equal light and dark periods) occurred between 15-sec. periods and continuous illumination. This minimum probably falls between 1- and 5-min. periods. The usual increase in assimilatory efficiency with increasing frequency of intermittency (for periods of less than 15 sec.) was found in young wheat plants, and it approached a limiting increase of 100 percent over continuous light.

The short-time relations reported for respiration and CO_2 assimilation in wheat strikingly confirm and correlate with much of the work on the fluorescence of chlorophyll in higher plants. Furthermore, in addition to the new results, most of the previous work on the time course of photosynthesis with algae is here verified for wheat.

Effect of light intensity on the photosynthetic efficiency of tomato plants, A. M. PORTER (*Plant Physiol.*, 12 (1937), No. 2, pp. 225–252, fig. 1).—In this study by the Michigan Experiment Station, Grand Rapids Forcing tomatoes were grown under average daily light intensities of 1,139.9, 583.1, and 261 foot-candles, with the following results: The stem elongation and leaf-area expansion responses were both continuously and finally greater with the lower light

intensities. When the light intensity reached a definite average the fruit set rather freely and developed. The percentages of dry matter, ash, water, fresh weight, and elaborated food materials correlated rather closely with the light intensity supplied. Light intensity proved to be the chief cause of differences in plant efficiency. Basal metabolism and its contributing factors were regulated by the amount of light received by the plants. The increase in multiple over simple correlations under each degree of light intensity furnished evidence of interrelationships between factors regulating plant food manufacture. The coefficients of determination demonstrated that light intensity alone accounts for 32.4 percent of the photosynthate variation, and that temperature and humidity are negligible factors only when correlated with light intensity—humidity becoming a critical factor in photosynthesis when light intensity is reduced.

Light intensity appeared to have a regulatory influence on the average amounts of chlorophyll per unit leaf area. The chloroplasts arranged themselves for the highest reception of light when the latter was reduced. In shaded plants the leaf anatomy was abnormal, consisting of loosely arranged, irregular spongy parenchyma cells and a reduction in the size, density, and number of palisade cells.

The average light intensity of 1,139.9 footcandles daily during growth had a greater effect in promoting chlorophyll formation, fruit production, and photosynthetic efficiency in tomatoes than the daily average of 583.1 footcandles. This, in turn, had a greater effect than the daily average of 261 footcandles.

The influence of light induction on the development of *Perilla ocymoides*, I [trans. title], E. D. BOUSLOVA and V. N. LUBIMENKO (*Compt. Rend. (Dok.) Acad. Sci. U. R. S. S., n. ser., 14 (1937), No. 3, pp. 143-147, figs. 2*).—Experiments with *P. ocymoides* (a short-day plant) led to the conclusion that, under conditions of natural lighting, intense light induces an acceleration in flowering, whereas feeble light retards the process. Shortening of the natural day of 16 hr. by division of the light period into 2 halves equal in intensity and quality of light increased the reaction induced by the intense light, accelerating flowering and at the same time causing a pronounced retardation in vegetative growth. Apparently it is not the length of daylight per se, but the duration of the action of strong and of feeble light which is important for the development of short-day plants.

Contribution to the theory of photoperiodism, II [trans. title], V. N. LUBIMENKO and E. D. BOUSLOVA (*Compt. Rend. (Dok.) Acad. Sci. U. R. S. S., n. ser., 14 (1937), No. 3, pp. 149-152, fig. 1*).—Continuing this series (see preceding entry), experiments with *Perilla ocymoides* indicated that shortening of the natural day to 7 hr. by shading isolated leaves results in acceleration of flowering of axillary buds and in retardation of stem elongation and leaf development. Cutting the midvein of the shaded leaf suppressed the effect of the shortened day. It is concluded that acceleration of flowering and retardation of vegetative development are due to the action of an especially active substance elaborated by the leaves and transferred to the axillary buds by the routes which serve to transport assimilatory substances from the leaves into the stem.

Nature of the Blackman reaction in photosynthesis, R. EMERSON and L. GREEN (*Plant Physiol., 12 (1937), No. 2, pp. 537-545, figs. 3*).—The results here presented led the authors to believe that no significant similarity exists between the Blackman reaction and the peroxidase decomposition. This leaves no support for the theory that the Blackman reaction involves the decomposition of some peroxide by catalase, but it is emphasized that no data thus far

known to the authors constitute conclusive proof that this reaction is not a peroxide decomposition. It is suggested, however, that the Warburg "acceptor theory", abandoned in favor of the peroxide theory, is still worthy of consideration as a basis for constructing a mechanism of photosynthesis.

Influence of weak electric currents upon the growth of the coleoptile, N. G. CHOLODNY and E. CH. SANKEWITSCH (*Plant Physiol.*, 12 (1937), No. 2, pp. 385-408, figs. 3).—The authors' main object was to check the hypothesis of Went (E. S. R., 64, p. 326) and of F. Kügl, who assumed that the translocation of the growth substance in plant organs is by cataphoresis. It was found that passage through the isolated coleoptile of oats and rye of a current of the order 10^{-7} - 10^{-6} a, directed from the base to the apex of the coleoptile, caused a noticeable growth acceleration which lasted for a short time and in most cases was followed by a definite retardation. If the current was increased by an initial strength during the test, the growth curve rose again for a short time. At the lower temperatures used an electric current directed to the coleoptile apex sometimes did not decrease growth but increased it somewhat, bringing growth to its normal level. A current of 10^{-5} - 10^{-6} a, directed from the coleoptile apex to its base, in most cases retarded coleoptile growth, the retardation continuing after the current was switched off. Analogous phenomena were noted also in uninjured oat seedlings when an electric current of the above order was passed through the coleoptile or through the whole plant.

The experiments described fail to confirm the hypothesis expounded by Went and by Kügl, i. e., the results presented seem to confirm the conclusion that the electric current affects the translocation of the hormone not directly as an electrolyte but indirectly through the complex system of the living protoplasm.

Exchange of electrolytes between roots and acid solutions, R. BEALL (*Plant Physiol.*, 12 (1937), No. 2, pp. 455-470, figs. 5).—*Lupinus albus* roots absorbed electrolytes from very dilute solutions of certain inorganic and organic acids. Absorption was greater and more rapid the higher the original concentration, and for any tested concentration it was greater as dissociation was more complete. There was apparently a rapid absorption of hydrogen ions, probably accompanied by some of other ions or of molecules (or both). Injury resulted in all cases, probably attributable to absorbed hydrogen ions in each instance except for propionic acid, where the undissociated molecules seem to have been largely responsible. In many cases rapid exosmosis from the roots eventually occurred, indicating increased permeability of the cell membranes or rapid disintegration of the cell contents. The influence of temperature, concentration of solution, and H-ion concentration on absorption and exosmosis and on growth and development of the seedlings are discussed, and a bibliography of 25 titles is included.

Electrical polarity and auxin transport, W. G. CLARK (*Plant Physiol.*, 12 (1937), No. 2, pp. 409-440, figs. 10).—Went's bipolar dye-uptake tests (E. S. R., 64, p. 326), used to substantiate his electrical transport theory, were repeated and confirmed. Positively charged dyes were taken up most by bases, negatively charged dyes by apexes, of *Impatiens* cuttings, which agrees with the fact that electrical measurements indicated *Impatiens* cuttings to have apical electro-negativity. Intact coleoptiles of *Avena* and *Zea*, stems of *Pisum*, and hypocotyls of *Impatiens* exhibited apical negativity when constancy of potential difference measurements was obtained. Cut sections of *Avena* and *Zea* coleoptiles and of *Pisum* and *Vicia* stems exhibited the same polarity as the *Impatiens* cuttings. Time was required to establish this polarity. The p. d.'s of sections were directly proportional to the length of the sections. The internal electrical

polarity of *Avena* coleoptiles was the same as the external. Inverting of sections inverted their electrical polarity, i. e., the morphological apices became electropositive to the bases. This inverted polarity disappeared with time. It was proportional to the length of the sections as in the case of upright sections, and the time of disappearance of the inverted polarity was proportional to the length of the sections.

A bibliography of 85 titles is included.

Tuberization of the Colorado wild potato as affected by X-radiation, E. L. JOHNSON (*Plant. Physiol.*, 12 (1937), No. 2, pp. 547-551, figs. 1).—"Radiation of wild potato tubers with light doses of X-rays failed to give increased number of progeny. Treatment of unsprouted tubers with moderate doses resulted in only a slight increase in number of progeny and in average weight per hill. Progeny from sprouted mothers which had been treated with 1,500 r-units gave the following percentage of increase over the controls: Average number of tubers per hill, 41 percent; average weight per hill, 56 percent; [and] average weight per tuber, 11 percent. The explanation advanced for the greatly increased production from treated tubers is that there is a probable increased rhizome development which results in greater tuber production. This is similar to the increased aerial branching which occurs in some other members of Solanaceae when young plants are treated with medium doses."

The respiration of bananas in presence of ethylene, R. GANE (*New Phytol.*, 36 (1937) No. 2, pp. 170-178, figs. 7).—"Evidence that ripe bananas produce ethylene is given. The effect on pea seedlings was paralleled by low concentrations of ethylene. Acceleration of ripening in unripe bananas by ethylene at 1 p. m. was similar to that induced by the metabolic products of ripe bananas. "It would appear that ethylene is a normal product of metabolism during the climacteric when it acts as an autocatalyst." Ethylene can be removed from air by ozone. The latter causes a retardation of normal ripening, probably by blocking of the stomata. Similar retarding effects were induced in fruits treated with H_2O_2 , iodine, and vaseline.

Lag in water absorption by plants in water culture with respect to changes in wind, J. D. WILSON and B. E. LIVINGSTON (*Plant Physiol.*, 12 (1937), No. 1, pp. 135-150, figs. 3).—"In a series of wind-tunnel tests on water absorption rooted cuttings were employed, mostly of *Salix purpurea*, but with *S. nigra* and *Cephalanthus occidentalis* in some of the tests. To make sure that the water supply to the roots would always be unlimited, solution cultures were employed such that the rates of water absorption and transpiration must have been generally limited or controlled only by internal characteristics of the plants themselves and by the evaporating power of the aerial environment. The procedures used are outlined, and the results are discussed in great detail.

The full effect of any pronounced alteration in air movement past plant or atmometer, which would measurably change the rates of transpiration or evaporation, was not immediately indicated in terms of bubble movement in the potometer. There was always a lag. Considerable increase or decrease in wind velocity apparently increased or decreased transpiration or evaporation almost instantly, but the lapse of the lag period was required before the potometer readings represented the transpiration or evaporation rates corresponding to the new air condition. The lag period was longer as the preceding steady rate of absorption for calm air had been slower, and conversely, thus showing a fairly clear diurnal march. It was apparently not generally and consistently related to the accelerating effect of wind on transpiration. This lag period is probably of considerable importance, especially with regard to plant absorption.

It seemed clear that the potometer lag represented hydrostatic readjustments of some sort within the plant, and that the lag period represented the time required for the propagation of a hydrostatic-pressure change from transpiring membranes in the leaves to the external solution bathing the absorbing membranes at the root surfaces. The lag period proved longer for plants with longer stems. It was also found that the introduction of solutes into the liquid around the roots retarded the absorption rate, either through an increase in the osmotic value of the medium or through specific physiological or chemical effects on the absorbing cells, or even on other tissues (e. g., stem and leaf).

Diastatic activity of orange leaves as affected by time, temperature, pH, and certain zinc salts, W. B. SINCLAIR and E. T. BARTHOLOMEW (*Jour. Agr. Res.* [U. S.], 54 (1937), No. 8, pp. 609-619, figs. 3).—In this investigation by the California Citrus Experiment Station no significant differences occurred in the diastatic activity of citrus leaves at pH 4.0-5.4. About 48 hr. were required to reach equilibrium with macerated citrus-leaf tissues. The diastase of the leaves had a maximum activity at 60°-65° C., the activity being much greater with young than with mature leaves but both showing similar responses to temperature. Leaves with adequate amounts of starch and diastase showed little activity on autolysis of the macerated tissue in distilled water. The natural starch of the leaf appeared to be bound by the chloroplast and was not reacted upon to any great extent by the naturally occurring diastase. A small increase in activity was noted when adjusted to pH 4.7, but when takadiastase was added to macerated leaf tissue at pH 4.7 the natural starch was hydrolyzed. However, if macerated leaf-tissue samples were added to a starch solution at pH 4.7 and incubated, the leaf enzyme converted the starch to reducing substances.

In zinc concentrations containing as much as 30 milligram equivalents of zinc per liter, takadiastase was found capable of converting starch to glucose quantitatively. These zinc concentrations appeared to produce no paralyzing effects on the enzymic activity. In tests performed in $ZnCl_2$ and $ZnSO_4$ solutions, the diastase in macerated leaf tissues produced about the same amounts of reducing substances in zinc concentrations containing 0-30 m. e. per liter.

The relations of the findings to the zinc therapy of citrus mottle-leaf are discussed.

The synthesis of sucrose by excised blades of sugar cane, C. E. HART (*Hawaii. Planters' Rec.* [Hawaii. Sugar Planters' Sta.], 41 (1937), No. 1, pp. 33-46, figs. 3).—It was found that the leaf blade manufactures sucrose when supplied with glucose and fructose, the process taking place in darkness and not requiring chlorophyll. Within the limits of 1-25 percent there was always a higher percentage of sucrose than of simple sugars in the blades, regardless of the concentration of glucose supplied. Synthesis was most efficient when the blades were supplied with a 5 percent solution of glucose, in which 83 percent of the sugar absorbed was converted into sucrose within 24 hr. Since the synthesis took place when the blades were supplied with glucose or fructose alone, and since sucrose contains both, a transformation from glucose to fructose and from fructose to glucose occurs in the leaf blades. The interconversion of glucose and fructose occurred equally well whichever sugar was supplied. Sucrose fluctuated more widely than the simple sugars in the blades supplied with glucose or fructose. The results thus agree with the viewpoint that the simple sugars are formed first in photosynthesis and are then converted into sucrose.

Effect of certain nutrient deficiencies on stomatal behavior, M. C. DESAI (*Plant Physiol.*, 12 (1937), No. 2, pp. 253-283, figs. 10).—In this contribution

by Cornell University the effects of deficiencies in potassium, phosphorus, and nitrogen were noted for *Zea*, *Pisum*, *Phaseolus*, *Nicotiana*, *Tradescuntia*, etc., the stomatal behavior being observed in the distal third of the lower leaf surface of the third or fourth leaf from the growing stem apex. Of the methods tried the direct visual and Lloyd's strip methods proved best, and a modification of the latter had many advantages over the former. On the whole, the general deficiency symptoms resembled those reported by others, and whenever these were strikingly shown the stomatal behavior was decidedly abnormal. In plants in full-nutrient cultures the stomata were more responsive to changing environal conditions than in those deficient in any of the three elements tested. Night opening of stomata was noted in practically all plants used except *Zea*. With excess potassium the plants were slightly smaller, their lower leaves mottled, and their stomata showed slight lethargic movement. The number of stomata per unit area varied little, but their distribution was much more irregular in the deficient plants. Apparently the stomatal behavior reflects the general metabolic condition. Subnormal behavior was accompanied by increased water requirement, decreased yield, and decreased size of the plants. The average stomatal aperture was proportional to the size of the plant as determined by nutrition.

It is apparent that the leaf activities (photosynthesis, respiration, and transpiration) control the stomatal behavior. "That the condition of stomatal mechanism itself does not change in deficient cultures is indicated by the fact that when placed in ammonium hydroxide solution the stomata in all cultures respond similarly."

Boron deficiency phenomena in grape seedlings in water culture tests [trans. title], W. MAIER (*Gartenbauwissenschaft*, 11 (1937), No. 1, pp. 1-16, figs. 10).—Using the v. d. Crone nutrient solution to which were added in various combinations traces of the elements Li, Cu, Zn, B, Al, Sn, Mn, Ni, Co, Ti, I, and Br, it was found that boron possesses a growth-promoting action, inducing a more vigorous shoot formation, higher fresh-weight production, and a significantly stronger development of the root system. None of the other trace elements tested could replace boron, a deficiency of which evoked various injuries to the seedlings, extending to the growing point of the shoots, the length of the internodes, the size, color, form, and arrangement of the leaf blades, and to the petioles. Boron-deficient seedlings also tended to form lateral shoots.

Selenium absorption by crop plants as related to their sulphur requirement, A. M. HURD-KARRER (*Jour. Agr. Res. [U. S.]*, 54 (1937), No. 8, pp. 601-608, figs. 4).—"Wide differences in the absorption of selenium from sodium selenate by 19 different crop plants grown in Keyport clay loam, untreated with respect to sulfur, were directly correlated with corresponding differences in their respective sulfur-absorbing capacities. The parallelism suggests that the sulfur requirement of the plant determines its tendency to absorb selenium."

The physiological anatomy of the legume testa: Contributions to the problem of hard seeds and to the significance of the strophiole [trans. title], K. ZIMMERMANN (*Landw. Vers. Sta.*, 127 (1936), No. 1-2, pp. 1-56, figs. 45).—This study of 24 species belonging to 14 genera and 8 tribes of the subfamily Papilionaceae of the Leguminosae dealt with the differing structure of the testa and its relation to the hard seed problem, the different types of strophiole and their relation to hard seeds, the developmental history of the strophiole, the relation between the thickness of the testa and the hard seed condition, and the microchemistry of the testa. The literature references cover over two pages.

GENETICS

Mendel and his place in the development of genetics, S. W. FERNBERGER (*Jour. Franklin Inst.*, 223 (1937), No. 2, pp. 147-172, figs. 4).—An account of the life and work of Gregor Mendel.

A glossary of genetic terms (*Jour. Heredity*, 28 (1937), No. 2, pp. 71-80).

Chromosome structure, B. R. NEBEL and M. L. RUTTLE (*Genetics*, 22 (1937), No. 1, p. 202).—This contribution by the New York State Experiment Station is an abstract of a "comparative study of the history of chromonemata in *Tradescantia*, *Trillium*, *Hordeum*, *Secale*, and *Dissosteira* (Orthopteran)."

On the morphology of the chromosomes in Gallinaceae, N. N. SOKOLOV, G. G. TINIAKOV, and J. E. TROTIMOV (*Cytologia*, 7 (1936), No. 4, pp. 466-489, figs. 19).—Comparison is reported on the morphology of the chromosomes of the common fowl (*Gallus domesticus*), Caucasian pheasant (*Phasianus colchicus*), silver pheasant (*Nycthemerus argentatus*), peacock (*Pavo cristatus*), guinea fowl (*Numidae melcagris*), turkey (*Melagris gallopavo*), and woodcock (*Tetrao tetrix*). Similarity of a number of the chromosomes in the different species seemed evident.

The genetical and mechanical properties of the sex-chromosomes.—II, Marsupials, P. C. KOLLER (*Jour. Genet.*, 32 (1936), No. 3, pp. 451-472, figs. 17).—Continuing studies on the sex-chromosomes of the rat during meiosis,² a report is given on the behavior of the sex-chromosomes during meiosis and the mitotic division immediately preceding it in *Dasyurus maculatus*, *Sarcophilus ursinus*, *Phascogaleus cinereus*, *Pseudochirus peregrinus*, and *Trichosurus vulpecula*. These results showed that the sex-chromosomes are composed of a deeply stained segment which is the genetically active region and a lightly stained segment not ordinarily visible during mitosis. This portion is more or less inert but contains the centrosome.

Cytology and breeding with fruits, B. R. NEBEL (*Zellforschung und Neuzüchtung beim Obst und bei der Rebe*. Stuttgart: Eugen Ulmer, [1936], pp. 58, figs. 10).—This little handbook prepared by a staff member of the New York State Experiment Station contains information on the structure and multiplication of the cell, on Mendelism, and on polyploidy, and reviews briefly the present status of genetic knowledge with regard to various fruits including the apple, pear, plum, cherry, peach, strawberry, raspberry, currant, and grape.

A study of the reaction of F_1 oat hybrids and their respective parental lines to inoculation with smuts and rusts, H. B. HUMPHREY and F. A. COFFMAN (*Phytopathology*, 27 (1937), No. 2, pp. 183-189).—From the results of inoculations of adult plants with spores of stem and crown rusts, the following conclusions are drawn:

Although parents and progeny were not treated alike, resistance to smut apparently is dominant in F_1 oat plants. Resistance to stem rust usually was dominant in F_1 plants, although subject to some variation. Resistance to crown rust usually was either dominant or intermediate in F_1 plants, but the apparent dominance was less pronounced than was resistance to stem rust. Resistance to either rust in F_1 individuals of certain crosses tended to approximate the type of resistance observed in the more resistant of the parental lines.

Inheritance of resistance to the loose and covered kernel smuts of sorghum, I, II, D. E. MARCY (*Bul. Torrey Bot. Club*, 64 (1937), Nos. 4, pp. 209-228, pls. 2, figs. 2; 5, pp. 245-267, figs. 2).—In part I of this investigation, Dwarf

² The genetical and mechanical properties of the sex-chromosomes.—I, *Rattus norvegicus*, J. P. C. KOLLER and C. D. DARLINGTON (*Jour. Genet.*, 29 (1934), No. 2, pp. 159-173, pl. 1, figs. 17).

Yellow Milo Hybrids, true breeding varieties of sorghum (*Andropogon sorghum*) were used. The hybrids studied fell into the three main categories of crosses (1) between resistant varieties, (2) between Dwarf Yellow milo and susceptible varieties, and (3) between feterita and susceptible varieties. The reactions to the two smuts (*Sphacelotheca sorghi* and *S. cruenta*) in the parental varieties corresponded closely, a variety giving high infections with one smut tending to do so with the other. except that the percentages of infection with *S. cruenta* were always lower.

As to infection results with hybrids, genetic evidence is presented that the two resistant varieties feterita and Dwarf Yellow milo possess different factors for resistance to *S. sorghi*. and it is demonstrated that the milo factor is epistatic to the feterita factor. It is also shown that these two varieties have in common at least one factor for resistance to *S. cruenta*, and that a cross between them gives only genetically resistant hybrids.

Inoculated with *S. sorghi*, hybrids between Dwarf Yellow milo and susceptible varieties showed a clear-cut segregation of resistant, segregating, and susceptible progenies, indicating that resistance may be governed by a single factor. Inoculated with *S. cruenta* they failed to show clear-cut segregation, indicating that reaction to this smut may be governed by more than one factor.

In part 2, Feterita Hybrids, it was found from seed germinations under four sets of environal conditions that the susceptible varieties gave highest infections when germinated in sand with 10 percent moisture. Dwarf Yellow milo maintained its resistance under these conditions, but feterita exhibited pathological effects of infection with *S. sorghi* not hitherto noted.

The four susceptible varieties Shallu, Dakota Amber sorgo, Dawn kafir, and Sumac sorgo and the two resistant varieties Dwarf Yellow milo and feterita were used as parents. When Dwarf Yellow milo was crossed with feterita about one-sixteenth of the F_1 was susceptible to covered smut, confirming the assumption that these varieties possess different resistance factors. When Dwarf Yellow milo was crossed with susceptible varieties about one-fourth of the F_1 was susceptible. It is suggested that Dwarf Yellow milo had brought into the crosses a factor for resistance (R) completely epistatic to a factor for susceptibility (S) introduced by the susceptible varieties. When feterita was crossed with susceptible varieties, the results indicated the interaction of the factor S and a factor for resistance introduced by feterita (B). Under highly favorable infection conditions S was shown to be epistatic to B, segregation in F_2 approximating 13 smutted to 3 normal plants. Under less favorable infection conditions the F_2 ratios were nearly reversed, approaching the ratio of 3 resistant to 1 susceptible. It is concluded that hybrids containing both S and B factors were extremely unstable in their infection reactions, and that the epistasis of S over B, or of B over S, was determined by environal conditions during germination.

Infection results with loose smut indicated that when Dwarf Yellow milo was crossed with susceptible varieties there was a two-factor interaction similar to that of feterita hybrids inoculated with covered smut. When feterita was crossed with susceptible varieties there was a clear-cut dominance of resistance, and the results indicated the interaction of three factors. No infected plants were obtained from crosses of feterita with Dwarf Yellow milo, indicating at least one factor for resistance in common. It has been suggested that the factors governing the reaction to *S. sorghi* may also determine that to *S. cruenta*, but that their effect is reversed. The presence of an additional factor influencing *S. cruenta* reactions has complicated the ratios, and, therefore, further data are needed for a more precise analysis of the present results.

[Experiments in animal genetics by the Storrs Station] ([*Connecticut Storrs Sta. Bul.* 214 (1937), pp. 20, 21).—The hatchability of eggs from normal hens, Creeper hens, and reciprocal crosses of Creeper and normal fowls, and the effect on egg production of removal of the comb from pullets are briefly noted.

[Papers on animal genetics] (*Amer. Soc. Anim. Prod. Proc.*, 1936, pp. 221-223, 229-232, 236-243, 247-265, fig. 1).—Brief reports were presented on the following subjects before the American Society of Animal Production: Observations on Reproductive Processes in Dairy Cattle and Their Relation to Breeding Efficiency, by L. E. Casida and W. G. Venzke (pp. 221-223); The Value as Sires for Swine Production of Three Inbred Boars, by R. T. Clark, O. M. Kiser, and L. M. Winters (pp. 229-232); Introductory Remarks Before the Symposium on the Relation of Nutrition to Genetics Research, by P. E. Howe (p. 236); The Role of Nutrition in Genetic Research, by W. V. Lambert, N. R. Ellis, W. H. Black, and H. W. Titus (pp. 236-243); Problems Involved in Breeding for Efficiency of Food Utilization, by M. Kleiber (pp. 247-253); Variations in the Softness of Lard Produced in the Record of Performance Testing, by J. L. Lush, B. H. Thomas, C. C. Culbertson, and F. J. Beard (pp. 258, 259); The Role of Nutrition in Genetic Research, by W. A. Craft and O. S. Willham (pp. 260-263); and Studies of Breeding for Increased Efficiency, by L. M. Winters (pp. 263-265).

[Papers on animal genetics] (*Genetics*, 22 (1937), No. 1, pp. 189, 190, 193, 194, 196, 198, 199, 204, 207; also in *Genet. Soc. Amer. Rec.*, 5 (1936), pp. 189, 190, 193, 194, 196, 198, 199, 204, 207).—Brief abstracts are given of the following papers, presented before the 1936 meetings of the Genetics Society of America: Two Hereditary Types of Hair Deficiency in the Deermouse, by F. H. Clark; Variation in the White-Footed Mouse, *Peromyscus leucopus noveboracensis*, by L. R. Dice; Evidence That Size of Head-Spot (Heatdot, Keeler) in the Mouse Is Not Controlled by Modifiers Distributed Among Many Chromosomes, and A Study of the Inheritance of Body Weight in the Albino Mouse by Selection, both by H. D. Goodale; Bilateral Gynandromorphism in the Barred Rock Fowl, by F. B. Hutt; Genetic Resistance to Deficiency of Vitamin B₁ in the Chick, by W. F. Lamoreux and F. B. Hutt; Malignant Lymphocytes From Perivascular Reticular Cells in Mice of a Leukemic Strain, by J. S. Potter and E. C. MacDowell; and An Analysis of the Action of Color Genes in the Guinea Pig by Means of the Dopa Reaction, by W. L. Russell.

[Genetic experiments with mice and rabbits], W. E. CASTLE (*Carnegie Inst. Wash. Yearbook*, 35 (1935-36), pp. 283-285).—In studies of size inheritance in mice it was found that both the blue dilute and brown color mutations accelerated general body growth. The short-ear and pink-eye genes retarded general body growth in addition to the specific retardation of growth in the ears by the former gene. A study of the linkage relation of the genes *rex*₁ and *rex*₂ in rabbits showed 17.2 percent crossing over in females. Linkage relations between the genes for Himalayan albinism, yellow fat, and brown pigmentation in the rabbit showed crossing over to be more frequent in females than in males— 14.4 ± 0.8 and 8.2 ± 1.7 percent, respectively, between *O* and *Y* and 28.4 ± 1.0 and 26.6 ± 2.8 percent, respectively, between *Y* and *B*. The infrequency of double cross-overs indicated interference. The gene *satin* was inherited independently of sex and the genes for *rex*₁, *rex*₂, *furless*, *English*, *albinism*, and *H₁* of the blood groups.

Genetical and cytological studies of the intergeneric hybrid of *Cairina moschata* and *Anas platyrhynchos* *platyrhynchos*, F. A. EL CREW and P. C.

KOLLER (*Roy. Soc. Edinb. Proc.*, 56 (1935-36), No. 3, pp. 210-241, pls. 4, figs. 31).—In these experiments 117 hybrids between the Muscovy ♂ and Aylesbury ♀ ducks were produced. Although the males had normal sex equipment and large testicles, they were infertile. The females possessed only a rudimentary ovary and oviduct, and exhibited no sex behavior. In the reciprocal cross, Aylesbury ♂ × Muscovy ♀, there were produced 73 hybrids. Both males and females had normal sex organs but both were infertile, although the females laid 164 small eggs. Description is given of the plumage characteristics of the hybrids.

Cytological studies showed the larger chromosomes of the two species to be similar morphologically. Chromosome counts from 48 to 72 were observed. Gametogenesis was abnormal to the extent that no viable gametes were produced. Sterility is suggested as due to complementary genetic factors which alter the relationship of chromosome pairing to spindle development. The abnormalities in the sex equipment are taken to suggest a lack of balance between the sex-determining factors of the two species.

Hybridization and acclimatization of animals, A. A. NURINOVA (NOURINOV) (*Trudy Nauch. Issled. Inst. Gibr. i Akklim. Zhivotn. Askaniia-Nova, Gibr. i Akklim. Zhivotn. (Works Sci. Res. Inst. Hybrid. and Acclim. Dom. Anim., Ascania-Nova, Hybrid. and Acclim. Anim.)*, 2 (1935), pp. 176, figs. [112]).—Brief results are presented in the English abstracts of the following papers: Pedigree Herd of Rambouillet Sheep at Askaniia-Nova, by M. F. Ivanov (pp. 11-26; Eng. abs., p. 26); Origination of a Mountain Merino, by M. F. Ivanov (pp. 27-41; Eng. abs., p. 41); Moufflon at Askaniia-Nova, by A. Brauner (pp. 42-48; Eng. abs., p. 48); Interbred Hybrids of English Mutton Rams and Fat-tailed Sheep, by F. M. Dobrogorski (Dobrogorsky) (pp. 49-71; Eng. abs., p. 71); Hybrids of the Bison American × Bison European Crossed with Grey Ukrainian and Crossbred Simmenthal Cattle, by I. S. Zhuravok (Jouravok) (pp. 72-88; Eng. abs., p. 87); Morphological Analysis of the Skulls of Young Bovinae at their Hybridization, by S. N. Bogolubskii (Bogolubsky) (pp. 89-111; Eng. abs., pp. 110, 111); Morphological Analysis of the Skulls of Adult Hybrids and the Initial Forms, by E. G. Andreeva (pp. 112-136; Eng. abs., pp. 135, 136); The Problem of Sterility of Hybrids, by A. V. Kukarkin and I. M. Khudjakov (Hudjakov) (pp. 137-143; Eng. abs., pp. 142, 143); Sex-linked Characters in Hybrids of the Musk Duck and Haki Duck, by I. I. Sokolovskaja (Sokolovskaya) (pp. 144-156; Eng. abs., pp. 153, 156); Results of Tests with Dilutors for the Sperm of Fowls, by I. M. Ogorodni (J. M. Ogorodny) (pp. 157-164; Eng. abs., p. 164); and Experiments of Distant Hybridization of Fowls with the Use of Artificial Insemination, by I. I. Sokolovskaja (Sokolovskaya) (pp. 165-176; Eng. abs., p. 176).

The origin of the JK strain of inbred mice: Twenty-two generations of mice without cancer, L. C. SEXTON (*Jour. Heredity*, 28 (1937), No. 1, pp. 41, 42, figs. 2).—The JK strain of mice originated by crossing a strain of mice carrying genetic factors for pinkeye, brown, agouti, short ear, and kinky tail with another strain carrying pinkeye, blue dilution, brown, and nonagouti. This strain was continued by brother and sister matings for 27 generations without the appearance of a single case of mammary carcinoma, and only one case of carcinoma of the lung occurred.

Hereford hogs, A. L. ANDERSON and J. C. BONEMA (*Jour. Heredity*, 28 (1937), No. 2, pp. 63, 64, fig. 1).—Description is given from the Iowa Experiment Station of a breed of hogs marked like Hereford cattle and having two record associations. Evidently Duroc Jerseys and Chester Whites were used principally as foundation stock.

Animal breeding plans, J. L. LUSH (*Ames. Iowa: Collegiate Press, Inc., 1937*, pp. VIII+350, figs. 41).—The principles of animal breeding and genetics are taken up under the following major headings, to which sections of the book are devoted: Background of animal breeding; genetic principles; breeding plans based on (1) selection, (2) relationship, and (3) somatic likeness; other topics concerning breeding plans; and topics relating to reproduction. Special attention is given to the practical application of genetic principles to breeding problems.

Linkage studies with curly₂ in the rat, C. T. BLUNN and P. W. GREGORY (*Jour. Heredity*, 28 (1937), No. 1, pp. 43, 44).—Linkage studies indicate that curly₂ (E. S. R., 75, p. 324) is not linked with the genes for agouti, hooded, dilute, hairless, kinky, albinism, and pinkeye in the rat. As *OU₂* is independent of *CU₁*, it is considered the marker of a seventh chromosome. About twice as many pink-eyed as P progeny were obtained in the backcross, but no explanation was presented for this situation.

Linkage studies of the rat (*Rattus norvegicus*), II, H. D. KING and W. E. CASTLE (*Natl. Acad. Sci. Proc.*, 23 (1937), No. 2, pp. 56-60).—Continuing these studies (E. S. R., 74, p. 21), data are presented from *F₂* and backcross progeny from matings between albino waltzing mice and colored nonwaltzers which showed linkage between the waltzing gene and albinism, and the waltzing gene and the gene for yellow.

Further backcross progeny also showed a higher percentage of waltzers among the albinos than among the colored individuals. Due to normal overlaps there was an excess in the number of nonwaltzers over waltzers, 1,581 to 553, but the sum of the crossovers, albino nonwaltzers (635) plus the colored waltzers (271) was 44.7 ± 0.7 of the total population of 2,139.

The order of the four genes in this linkage group is suggested as color at one end of the chromosome, red-eyed yellow 0.3 unit away, with the pink-eyed yellow gene 20 units and the waltzing gene 45 units distant at the other end of the chromosome.

The genetics of tumour formation in mice in relation to the gene T for brachyury, A. M. CLOUDMAN and C. C. LITTLE (*Jour. Genet.*, 32 (1936), No. 3, pp. 487-504, figs. 2).—Study was made of the relation of the incidence of mammary and nonmammary tumors to the brachyuric T gene in mice by crossing females from the *dba* strain having a high mammary and a low nonmammary tumor incidence with males from the Zavadskaja stock (some brachyuric) having low mammary and high nonmammary tumor incidence. The *F₁* males were crossed with a third strain free from mammary and having a low incidence of nonmammary tumors. No significant difference in the occurrence of the tumors in the brachyuric and normal virgin females was noted. On account of the development of mammary tumors in 76.68 percent of the females of the *F₁* generation the action of dominant factors is suggested, but only 5.66 percent developed tumors in the progeny produced by mating the *F₁*s to the low tumor strain. These results indicate that tumor incidence is not a simple Mendelian phenomenon and point toward the operation of extrachromosome factors.

The genetic basis for resistance and susceptibility to *Salmonella aertrycke* in mice, H. O. HETZER (*Genetics*, 22 (1937), No. 2, pp. 264-283, figs. 2).—Results are reported from the Iowa Experiment Station on the increased resistance of mice to inoculation with standard doses of *S. aertrycke* during eight generations after the sixth generation continued from survivors of Schott's strain (E. S. R., 67, p. 120). The mortality in successive generations continued to decrease to the point where it seemed advisable to use larger doses

of the pathogene to bring about selection of animals with a higher concentration of genetic factors for resistance.

In reciprocal crosses with susceptible stock males of the resistant stock produced progeny with less susceptibility to the disease than the corresponding progeny of females selected from the resistant strain. This disproved the transmission of acquired immunity, as males are not known to transmit passive immunity to their offspring.

Inbreeding increased to over 80 percent in the thirteenth and fourteenth generations, but the degree of inbreeding was in no way associated with the mortality of the progeny of individual matings and there were marked differences in the ability of the progeny of different parents to survive. Mortality of the progeny from different matings in the twelfth and thirteenth generations ranged from 0 to 88 percent.

Age and weight were not important factors in resistance, although males were slightly more susceptible than females. There were differences in the mortality of the progeny from reciprocal crosses, but the total mortality of the F_1 progeny of the resistant \times two susceptible stocks was 17 percent, nearly as low as the mortality of the resistant stock.

Mortality in the backcross generation to the susceptible strain was about 50 percent. Significant differences in the mortality of reciprocal backcrosses to one susceptible strain suggested a cytoplasmic influence, but in general dominant multiple genetic factors were principally responsible. A mortality of 80 percent, below that of both susceptible stocks, was observed among the F_1 progeny of these stocks, suggesting the complementary action of genes for resistance. There was no evidence of linkage of resistance with several genes for color.

Does the blood contain factors which reflect inherited characteristics? (*Wisconsin Sta. Bul.* 438 (1937), pp. 43-45).—Reference is made to studies by M. R. Irwin and by Irwin and L. C. Ferguson of differences between the blood of species of disease-resistant birds and animals (*E. S. R.*, 76, p. 319) and differences in the blood of individuals which have and have not recovered from abortion.

The lethal nature of flightlessness in the fowl, D. C. WARREN (*Jour. Heredity*, 28 (1937), No. 1, pp. 17, 18, fig. 1).—Further data are presented on flightless fowls (*E. S. R.*, 69, p. 31) to suggest that the so-called flightless birds were heterozygous. In the F_1 such birds were approximately twice as numerous as normals. However, a few featherless birds with abnormal beaks and toenails were produced in the F_2 generation. Although they were less than 25 percent of the population, it is suggested that such represent birds homozygous for the flightless gene, which proved, in the main, lethal. A large number of homozygous birds were thought to die, and those raised beyond six months did not show inclination to mate or develop normal secondary sexual characteristics.

Study of reproductive processes in dairy cattle casts light on breeding troubles (*Wisconsin Sta. Bul.* 438 (1937), pp. 46, 47).—Brief results are reported by L. E. Casida and W. G. Venzke on changes in the uterus of dairy cattle following calving and the development of follicles in the ovaries preceding ovulation.

The influence of low temperature on embryonic development in the bat [trans. title], M. EISENTRAUT (*Biol. Zentbl.*, 57 (1937), No. 1-2, pp. 59-74, figs. 3).—In three series of experiments it was shown that the rate of development of the bat embryo in utero was closely related to the surrounding temperatures.

The anatomy of the male genital ducts in the fowl, J. C. GRAY (*Jour. Morph.*, 60 (1937), No. 2, pp. 393-405, pls. 4).—A description of the microscopic anatomy of the tubuli contorti, tubuli recti, rete testis, ductuli efferentia, and epididymal ducts of the testes, and the vas deferens in male fowl.

Weights and linear dimensions of the skull and some of the long bones of the skunk (*Mephitis mesomelas avia*), H. B. LATIMER (*Jour. Morph.*, 60 (1937), No. 2, pp. 379-391, fig. 1).—Measurements and weights on skulls and 6 long bones from 74 male and 69 female skunks were in nearly all cases greater in the males than in females. There were relatively high correlations between the weight and the length of the skull bones and the corresponding measurements of the other bones.

The physiology and pharmacology of the pituitary body, H. B. VAN DYKE (*Chicago: Univ. Chicago Press*, 1936, pp. XVII+577, figs. 55).—A summary of the literature of the action on various parts of the body of the hormones of the pituitary, including especially the growth-promoting and gonadotropic hormones, galactin, and related work on the action of other hormones, such as oestrin, progesterone, and prolactin, and various glands of internal secretion. The extensive bibliography lists 3,081 references.

The modification of sex development in the chick embryo by male and female sex hormones, B. H. WILLIERS, T. F. GALLAGHER, and F. C. KOCH (*Physiol. Zool.*, 10 (1937), No. 1, pp. 101-122, pls. 2, figs. 14).—A more detailed account of experiments previously noted (*E. S. R.*, 70, p. 778).

[Relation of hormones to reproduction], I. A. REMEZOV (I. REMESOW) (*Ark. Biol. Nauk [Leningrad]*, 41 (1936), No. 3, pp. 33-90; *Ger. abs.*, pp. 152-154).—Brief abstracts are presented in German of the Russian papers dealing with the standardization and dosage of female sex hormones; the principle of the synthesis of sex hormones from sterines and cholic acid—theoretical foundations and the possible methods of the synthesis of the hormone of the corpus lutea (luteo-sterone), the follicular hormone (folliculo-sterone), and male sex hormones; and the nomenclature of the sex hormones.

The assay of transdehydroandrosterone and its effects on male and female gonadectomized rats, V. KORENCHIEVSKY and M. DENNISON (*Biochem. Jour.*, 30 (1936), No. 8, pp. 1514-1522).—Studies with synthetically prepared transdehydroandrosterone showed the effects of this hormone to be small when administered to normal and gonadectomized male and female rats.

An extract from the adrenal gland causing luteinisation of the ovaries and endometrial hyperplasia, R. ALLEN and G. BOURNE (*Austral. Jour. Expt. Biol. and Med. Sci.*, 14 (1936), No. 1, pp. 45-50, figs. 7).—Extracts of adrenal tissue from kangaroos and cows were found to cause luteinization and uterine hypertrophy similar to that induced by the anterior pituitary-like hormone when injected into immature female rats. Cortin injections over long periods had similar luteinizing effects but caused less uterine hypertrophy.

The progesterone-like action of testosterone and certain related compounds, M. KLEIN and A. S. PARKES (*Roy. Soc. [London], Proc., Ser. B*, 121 (1937), No. 825, pp. 574-579, pl. 1).—In experiments with immature rabbits progestational proliferation of the uterus was induced by methyltestosterone, methyl- and ethyl-dihydrotestosterone and methyl- and ethyl-androstenediol. Testosterone showed some and androstenedione slight activity. These male hormone compounds were active even after removal of the ovaries.

The effect of a lysine deficient diet on the estrous cycle, P. B. PEARSON (*Amer. Jour. Physiol.*, 118 (1937), No. 4, pp. 786-791, figs. 3).—In studies at the California Experiment Station, oestrous cycles which ceased in the rat on a diet containing 18 percent gliadin as the chief protein were restored when 0.6 percent of *D*-lysine dihydrochloride was added to the ration.

Castration in the rat with and without removal of the epididymides, J. J. LAWLESS (*Anat. Rec.*, 66 (1936), No. 4, pp. 455-473).—Castration of rats by removal of the testes and leaving the epididymides intact had the same influence on the growth and development of the animals and various organs and bones as ordinary castration with the removal of the testes and epididymides. The results were based on rats castrated at 21 to 23 days of age and autopsied at 88 to 109 days of age.

Testicular heterotransplantation in rats and mice, L. G. BROWMAN (*Jour. Expt. Zool.*, 75 (1937), No. 2, pp. 283-311, pls. 2).—Autotransplantation of testicular tissue to the scrotum of rats and mice permits continued spermatogenesis and the production of sufficient male hormone to maintain normal secretory epithelium in the seminal vesicles. Portions of or the entire grafts underwent calcification, especially in the heterotransplanted tissue, and the seminal vesicles of such hosts were of the castrate type. There was no evidence of significant production of male hormone in heterotransplants, even after special treatment to aid in the adaptation of such tissue and the liberation of the male hormone.

The cause of reduced litter size in mice after X-raying the sperm [trans. title], **P. HERTWIG and H. BRENNKE** (*Ztschr. Induktive Abstam. u. Vererbungslehre*, 72 (1937), No. 3-4, pp. 483-487, figs. 2).—Reduced litter size in mice mated with males treated with varying doses of X-rays was attributed to abnormalities in the process of development of the fertilized ova. Several nucleoli were formed in the fertilized cell and division was irregular. The X-ray treatment of the males accordingly reduced the litter size from an average of 5.69 to about 2 to 3. The proportion of the ova showing abnormal development was related to the size of the X-ray dose.

Analysis of variation in the sexual cycle and some of its component phases, with special reference to cattle, A. B. CHAPMAN and L. E. CASIDA (*Jour. Agr. Res. [U. S.]*, 54 (1937), No. 6, pp. 417-435, figs. 2).—Based on an analysis of 690 oestrous cycles in normal dairy cattle, the Wisconsin Experiment Station found that individuality was an important cause of variations and there was a definite tendency for successive cycles in the same individual to be of similar length. Copulation without conception prolonged the next cycle about 4 days. As age increased there was a slight but significant increase in the length of the cycle with a reduced amount of variation. Significant seasonal differences in the duration of the cycles were noted. Successive periods between parturition and oestrous in the same individual tended to be of similar lengths. Related data on the sexual cycle and its component phases in the sheep, pig, horse, monkey, man, and baboon are discussed in connection with the interpretations.

Light and the sexual cycle of game birds, L. B. CLARK, S. L. LEONARD, and G. BUMP (*Science*, 85 (1937), No. 2205, pp. 339, 340).—In studies at the New York State Game Farm and Union College, continuous lighting beginning February 10 brought grouse into laying about one month earlier than in case of the controls. By keeping grouse and pheasants in the dark from February 10 to June 20, egg laying was prevented. Continued light did not prevent retrogression of the gonads after the conclusion of the breeding season. Stimulation of immature and adult males was effected by hypophyseal extracts, leading to the conclusion that the light acts through the hypophysis.

A double sheep pregnancy with a single corpus luteum, W. L. HENNING (*Jour. Heredity*, 28 (1937), No. 2, pp. 61, 62, fig. 1).—Among 675 sheep fetuses examined for sex at the Pennsylvania Experiment Station, two fetuses about 130 days in age were found with joined allantoic membranes and with a single

corpus luteum in the ovaries. This is therefore suggested as a case of monozygotic twinning.

Some observations upon the mitotic and meiotic divisions in the Wistar rat.—III, Effects produced by experimental cryptorchidism, W. BRYDEN (*Cytologia*, 7 (1936), No. 4, pp. 499-503, figs. 4).—Continuing this series (E. S. R., 76, p. 777), differences in the late prophase and metaphase stages of cell division were noted as a result of placing the testes of rats in the abdominal cavity for from 12 to 28 days, yet the chiasma frequencies did not appear to be affected by the increased temperature. The meiotic and mitotic divisions showed little change as compared with that observed in other animals as a result of cryptorchidism.

Hermaphroditism in goats, S. A. ASDELL (*Dairy Goat Jour.*, 14 (1936), No. 10, pp. 3, 4).—A description of hermaphroditism in goats with reference to the fact that all observed hermaphrodites are hornless.

FIELD CROPS

The effect of electric current on certain crop plants, C. S. DORCHESTER (*Iowa Sta. Res. Bul.* 210 (1937), pp. 37, figs. 9).—The possible effects of weak electric currents, similar to those existing in nature, upon crop plant growth and certain phases of the environment were studied in experiments using the earth-air currents collected and discharged by means of elevated metal brushes, and using currents generated as the result of differences in potential between buried, aurally connected, copper and zinc electrodes, sometimes augmented by dry cells placed in the circuits. In both types the currents developed were applied to the root areas of the plants.

Currents obtained by installation of elevated metal brushes connected with buried wires transversing the root areas of field crops apparently had little effect on yields of corn, soybeans, turnips, string beans, chard, and beets, the last two making the largest increases. Currents passing through elevated metal brushes during fair weather changed direction frequently and were of the order of from 5×10^{-10} a to 1×10^{-9} a, but varied greatly during unsettled weather both in direction and magnitude, the highest value being of the order of 200×10^{-9} a. Intensities of currents measured in the soil and along the buried conductor at various distances from one of the elevated brushes seemed to bear no relation to intensities measured where the conductor entered the soil.

Application of currents ranging in intensity from 7,000 to 20,000 v to roots of oats in greenhouse flats did not produce significant variations in yields of grain and straw. Greenhouse treatments in which an electrode of copper and one of zinc were buried at opposite ends of the test soil area and connected aurally by copper wire produced significant increases in yields of oats in the first year of the experiment. Currents measured were of the order of from 0.5 to 1.5 ma. In the second year the grain and straw yields were not increased by treatment with electric current, while root yields were decreased significantly. In this test one or two dry cells were included in the circuit for each treated lot, and current intensities ranged as high as 4 ma. In field trials with oats the copper-zinc electrodes combination, with dry cells included in the circuits, provided current intensities ranging from 2 to 55 ma but failed to affect yields significantly, and apparently did not affect the percentage of total nitrogen of oats.

Except in determinations made in connection with the field tests, a rather definite relationship between electrical treatment and numbers of soil micro-organisms was observed throughout the series of experiments. In the 1932

greenhouse experiment, comparison of 24 samples showed increases for the electrically treated lots of from 14 to 123 percent and for 20 samples in 1933 of from 15 to 23 percent. Further proof was provided by the carbon dioxide determinations, a weak current of 0.1 ma producing appreciable increases in amounts of carbon dioxide formed and a relatively strong current of from 10 to 15 ma resulting in pronounced decreases.

A humidity- and temperature-control cabinet for growing plants, C. O. GRANDFIELD and F. J. ZINK (*Jour. Agr. Res.* [U. S.], 54 (1937), No. 7, pp. 503-508, figs., 3).—The cabinet for the control of humidity and temperature, for use in agronomic experiments with plants growing under glass and exposed to natural light, developed by the Kansas Experiment Station in cooperation with the U. S. Department of Agriculture (E. S. R., 75, p. 769), is described in further detail. The relative humidity is controlled by use of an aqueous solution of sulfuric acid in the inner chamber of the cabinet, and temperature is controlled entirely by radiation through the glass into the inner chamber. Use of the cabinet may be extended to studies with soil-moisture control.

[Field crops experiments by the Storrs Station] ([Connecticut] Storrs Sta. Bul. 214 (1937), pp. 7-10).—Brief reports are again (E. S. R., 75, p. 194) given on the effects of time and frequency of cutting alfalfa under different fertilizer treatments; the effects on alfalfa of amount and depth of application of limestone; the effects of fertilizer treatments on the soil, flora, and production of permanent pastures; response of pasture species to plant nutrients; the adaptability of varieties and species of grasses and clover for pastures; and fertilizer experiments (involving lime and magnesia) with potatoes.

[Experiments with rice and other crops in Louisiana, 1935-36], J. M. JENKINS (*Louisiana Sta., Rice Sta. Bien. Rpt. 1935-36, pp. 4-12*).—Agronomic research with rice (E. S. R., 73, p. 462), continued in cooperation with the U. S. D. A. Bureau of Plant Industry and reported on briefly for 1935 and 1936, included variety, date of seeding with grain drill and in water, date and manner of submergence tests, rice rotations, and studies of the effect of holding water on rice lands in alternate years when not sown to rice. Breeding work is reviewed in a special article, Progress in Improving Rice Varieties, by N. E. Jodon (pp. 10-12). Work with other crops included variety tests with cotton, corn, and soybeans; fertilizer tests with cotton; date of planting tests with corn, grain sorghums, and sorgo; a cotton and corn rotation; and a permanent pasture experiment.

[Field crops work in New Jersey] (*New Jersey Stat. Rpt. 1936, pp. 28-32, 69, 70, 96*).—Progress reports are again made on agronomic research (E. S. R., 75, p. 616), including breeding work with corn, rye, barley, fescue, bentgrass, and alfalfa; variety tests with corn, wheat, oats, barley, seed flax, soybeans, and annual hay crops; planting tests with oats; fertilizer experiments with potatoes (including placement tests); increasing the protein content of timothy by nitrogen fertilization at heading; pasture experiments; experiments on establishing and maintaining turf, including studies on the rate of penetration of lime on permanent sod, and the seasonal fluctuation in supplies of available plant food under a variety of conditions; experiments with winter green manures (E. S. R., 76, p. 324); and studies on the relation of fungi to seed germination, on abnormalities in the germination of beans, and on the longevity of agar cultures of rhizobia.

[Field crops research in Wisconsin, 1935-36] (*Wisconsin Sta. Bul. 438 (1937), pp. 65-72, 73-81, 82-86, 93-97, 99, 100, figs. 7*).—Agronomic investigations (E. S. R., 75, p. 475) for which progress is reviewed in these pages were concerned with the merits of seed from hybrid corn for planting, by N. P. Neal;

the introduction of identifying color factors into hybrid corn, by R. A. Brink and Neal; studies of the effect of color on corn yield; improvement in the design of the bin drier for seed corn, by A. H. Wright and F. W. Duffee, and the development of a slatted floor drier; a study of grades for shelled corn, by Wright; comparison of yields of rye, barley, oats, and winter and spring wheat at several branch stations, and of the yields of corn, sunflowers, and rutabagas for silage at the Ashland Substation, all by E. J. Delwiche; comparison of barley varieties for malting quality, by J. G. Dickson et al.; the use of small, light combines for harvesting reed canary grass seed, by E. D. Holden, and the palatability of canary grass for cattle; pasture management research near Fort Atkinson, including studies on the value of various pasture grasses, especially Sudan grass, by O. S. Aamodt, F. Boyd, and E. Truog; the response of bluegrass pasture to nitrogen fertilization and rotational grazing in studies at the station, by G. B. Mortimer, I. W. Rupel, Aamodt, and H. L. and G. H. Ahlgren; the determination of pasture yields through actual grazing, by Rupel, G. Bohstedt, Aamodt, H. Ahlgren, and E. J. Graul; the reduction of grub infestation by renovation of old bluegrass pastures with legumes, by R. F. Fuelleman and L. F. Graber; the development of nonbitter sweetclover, by W. K. Smith, Brink, W. L. Roberts, and K. P. Link; the smothering effect of ice sheets on alfalfa, by V. G. Sprague and Graber; causes of seed failure in alfalfa, by D. C. Cooper and Brink; the development of improved winter-hardy and wilt-resistant varieties of alfalfa, by Brink and F. R. Jones; the superiority of potatoes grown on peat land over those from other types of soil, variety and planting tests with oats on peat land, and cultivation experiments with corn on sandy lands at Hancock, all by A. R. Albert; blackening of potatoes during cooking attributable to lack of potassium and possibly deficiency in one of the less common elements, by W. E. Tottingham, A. F. Ross, and R. Nagy; fertilizer experiments with potatoes at Ashland and Spooner, by F. L. Musbach; and potato breeding and improvement, by G. H. Rieman. A number of the investigations were in cooperation with the U. S. Department of Agriculture.

British grasses and their employment in agriculture, S. F. ARMSTRONG (*Cambridge, [Eng.]: Univ. Press; New York: Macmillan Co., 1937, 3. ed., pp. [X]+350, figs. 194*).—Part 1 of this revision and enlargement of a book noted earlier (E. S. R., 40, p. 525) describes and illustrates native species. Part 2, the agricultural section, deals with the choice and cultivation of grasses as crops, incorporating results of recent research on grasses and grassland, and includes a chapter on lawns and greens.

High-grade timothy and clover hay: Methods of producing, baling, and loading for market, E. O. POLLOCK and W. H. HOSTERMAN (*U. S. Dept. Agr., Farmers' Bul. 1770 (1937), pp. II+17, figs. 4*).—Practical information is given on the importance of timothy and clover hay as a hay crop in the United States; on its quality as affected by time of cutting and maturity at cutting, weather damage, fermentation, and content of foreign material; on how to produce high-quality hay by good stands, proper curing and storage methods, and minimizing rain damage; and on the preparation of hay for market and loading it on cars or trucks.

An all-year pasture system for Missouri, W. C. ETHERIDGE, C. A. HELM, and E. M. BROWN (*Missouri Sta. Circ. 193 (1937), pp. 12, figs. 3*).—This is a revision of circular 186 (E. S. R., 73, p. 604).

Dry-land crops at the Tucumcari Field Station, D. R. BURNHAM and J. S. COLE (*New Mexico Sta. Bul. 244 (1936), pp. 48, figs. 10*).—Experimentation in growing field crops on dry land in cooperation with the U. S. Department of Agriculture is reported for the period 1929-35, supplementing previous work

(E. S. R., 62, p. 32). Descriptions of climatic and other environmental conditions are included, and suggestions are made for the control of soil blowing (E. S. R., 76, p. 27).

The better adapted crops include grain sorghum, sorgo, broomcorn, cowpeas, beans, and peanuts. Crops following pinto beans in rotation have yielded about as much as on fallowed land. Cowpeas returned good yields of excellent hay, and crops after cowpeas outyielded those following sorghums or corn. Cowpeas or beans, if grown on sandy soil, should be planted in narrow strips, alternating with strips of crops not conducive to soil blowing during winter and spring after harvest. Fallowing has not increased the yields of following crops enough to be economical, and fallow land is subject to blowing. Listing, preceded by early spring cultivation to prevent soil blowing and to kill early weeds, has been practical for planting row crops. Barnyard manure, but not green manure, has increased yields of succeeding crops. Crop rotation, especially when including cowpeas or beans, is preferable to continuous planting.

Dwarf Yellow milo and certain of the dwarf, upright, early, combine-type milo-kafir hybrids are preferred for grain production, and Sunrise has been the best kafir for bundle feed. Dwarf hegari has produced well in favorable years, but erratically in dry years. Sumac sorgo combines high yield with good quality feed, but produces much less seed than Kansas Orange and Sourless, which mature earlier and yield about 80 percent as much total tonnage. Broadcasted or drilled sorghums averaged lower in yield than sorghums planted in rows. Broadcasted kafir or sorgo is suitable for irregularly shaped areas in contour plantings. Sudan grass, excellent for summer pasture, should be planted in rows for either hay or pasture and as late as early August as a catch crop or on sandy land where soil blowing is troublesome. Its hay is good but it yields much less than that of the better sorgos. Scarborough is the best broomcorn variety tested. The crop, if the stalks are not grazed, is valuable in preventing soil blowing on light land.

Spanish peanuts mature early and have been among the highest yielders of nuts. The later-maturing Virginia Runner and Virginia Bunch produce more hay but will not mature fully if planted later than May 15. Blue grama, brome grass, and crested and slender wheatgrasses have made stands only under exceptionally favorable conditions. Alfalfa and sweetclover have been planted successfully in rows on undisturbed drilled sorghum stubble, and on well-chosen sites alfalfa may produce enough hay, seed, or pasture to be profitable.

The time factor in pollen-tube growth and fertilization in barley, M. N. POPE (*Jour. Agr. Res. [U. S.]*, 54 (1937), No. 7, pp. 525-529, pls. 2, fig. 1).—Pollen germinated within 5 min. after reaching the stigma in Hannchen barley (*Hordeum distichon palmella*) under the greenhouse conditions as described. The male gametes had entered the pollen tube within 10 min. and had reached the level of the micropyle in 40 min. Within 45 min. the two male gametes had entered the egg sac through the micropyle and one had reached or entered the egg nucleus and the other, one of the polar nuclei. The fusion nucleus produced division figures and daughter endosperm cells within 6 hr. after pollination. Division figures were present in the fertilized egg at the 14-hr. stage, at which time from 6 to 8 naked, rapidly migrating endosperm cells were in the ovule. The first division of the fertilized egg was completed within 15 hr. after pollination.

Analysis of covariance of yield and time to first silks in maize, G. W. SNEDECOR and G. M. Cox (*Jour. Agr. Res. [U. S.]*, 54 (1937), No. 6, pp. 449-459,

figs. 2).—An analysis of the covariance between yield and time to first silks among inbred lines and 14 varieties of corn, considered by Jenkins (*E. S. R.*, 62, p. 420), was made at the Iowa Experiment Station. The 14 variety regressions of yield on time to first silks did not differ significantly among themselves, presenting no evidence against the hypothesis of a common regression in all the inbred lines. The average within-variety regression differed significantly from that between-variety means, showing that variety mean yields do not respond to variety earliness in the same manner as the yields of inbred lines respond to their earliness. The variety means departed significantly from their regression, emphasizing this finding. A convenient method for averaging the correlation coefficients of the 14 varieties and an easy test appropriate for field plot trials are included.

Effects of age, size, and source of seed on the corn crop, T. A. KIESSELBACH (*Nebraska Sta. Bul. 305 (1937), pp. 16, figs. 4*).—Results of experiments bearing directly on questions most common under conditions of seed scarcity are reported. See also earlier notes (*E. S. R.*, 45, p. 230; 49, p. 225).

New seed corn is preferred to old seed, although seed up to 4 yr. old when well preserved and of strong germination has proved satisfactory. Small but sound ears and kernels, stunted by drought, can be used as seed. In years of late maturity, seed corn may be harvested 1 or 2 weeks before fully ripe without impairing seed value if properly cured. Home-grown seed of recognized established varieties should be given first choice, although suitable seed may be introduced from a distance. When grown comparably at Lincoln, corn from extreme southeastern Nebraska ripened 11 days after corn from northeastern Nebraska, and a month later than that from the extreme southwestern panhandle section of the State. Regional strains from various parts of the United States, which required less than 100 days to ripen at Lincoln, averaged 676 sq. in. of leaf area per stalk, while those requiring more than 140 days averaged 2,027 sq. in. The water needed in normal growth of corn has been found to increase with vegetative size and lateness of ripening. If seed of open-pollinated varieties is to be brought to eastern Nebraska from other States, the most suitable sources appear to be points in Iowa and Illinois of about equal or slightly more northern latitude. Seed from northern Ohio and southern Wisconsin and Michigan might be usable in central Nebraska in an emergency. Short-season plains States may be considered as out-of-State seed sources for western Nebraska.

In general, within a locality in Nebraska seed corn may be interchanged without respect to the soil fertility level. Irrigated seed corn from central and western Nebraska may be moved a considerable distance to dry land east or south, but may prove too large and late for dry land in the same locality. In contrast with open-pollinated varieties, the adaptation of any specific corn hybrid is unaffected by locality or condition under which the seed is produced, depending entirely upon the component inbred lines.

Fertilizers for cotton on the Red and Mississippi River alluvial soils of Louisiana, H. C. LOVETT and F. L. DAVIS (*Louisiana Sta. Bul. 284 (1937), pp. 8, fig. 1*).—In cooperative fertilizer tests with cotton, 1927–36, on Red River (Miller and Yahola very fine sandy loams) and Mississippi River (Sarpy very fine sandy loam and Sharkey clay loam) alluvial soils, yield increases followed application of nitrogen and phosphorus but not potassium. From 30 to 42 lb. of nitrogen per acre have given the most profitable increases on all soils, and can be supplied by applying 200 lb. of fertilizers containing from 15 to 20 percent nitrogen. On soils in which cropping is depleting reserves of available phosphorus, profitable increases will be obtained from using about

24 lb. of phosphoric acid per acre, to be supplied by 300 lb. of a 12-8-0 mixture. Net profits from various treatments are shown

Fertilizers for cotton on the Coastal Plain soils of Louisiana, F. L. DAVIS and H. C. LOVERT (*Louisiana Sta. Bul. 285 (1937), pp. 10, figs. 2*).—Results of cooperative fertilizer tests with cotton, 1927-36, suggest the use of 300 lb. per acre of 8-8-8 fertilizer on the hill (Orangeburg, Ruston, Greenville, and Bowie fine sandy loams) and upland valley (Kalmia and Ochlockonee very fine sandy loams) soils and 400 lb. per acre of 6-10-7 fertilizer on the loessial bluffs (Granada silt loam) and flatwoods soils (Caddo very fine sandy loam) east of the Mississippi. Net profits from various treatments are shown.

Fertilizers for cotton on the prairie soils of southwest Louisiana, H. C. LOVERT and F. L. DAVIS (*Louisiana Sta. Bul. 286 (1937), pp. 8, figs. 2*).—Cooperative fertilizer tests with cotton, 1928-36, on prairie soils in southwest Louisiana (Crowley silty clay loam, Crowley silty clay, and Olivier silt loam) show decided response to potassium, especially in combination with nitrogen and phosphorus. Application of as much as 600 lb. of 4-8-6 fertilizer is advised except in areas where cotton is damaged excessively by rust, where a 4-8-10 mixture should be used. Net profits from various treatments are shown.

Good varieties of cotton for Missouri, B. M. KING (*Missouri Sta. Circ. 194 (1937), pp. 8, fig. 1*).—Cotton varieties indicated for Missouri conditions from results of tests at Sikeston on Lintonia silt loam and in cooperation with farmers on other soil types included Delta and Pine Land (Deltapine) 11 and 11A and Stoneville 5 and 5A for a wide range of soil conditions (except very fertile soils), Stoneville 4A (Ambassador) for very fertile soils and for late planting and planting along the northern limits of cotton culture on most soils where wilt and rust are not serious, and Arkansas Rowden 40 for sandy soils where wilt and rust commonly occur. Desirable features in a variety, varietal deterioration, and other factors in producing good cotton crops are discussed briefly.

Cotton varieties grown by Tennessee farmers, with regional comparisons, C. E. ALBRED, P. B. BOYER, G. H. HATFIELD, N. J. STANFORD, and B. D. RASKOFF (*Tennessee Sta., Agr. Econ. and Rural Sociol. Dept. Monog. 35 (1937), pp. [I]+III+39, figs. 19*).—Data were obtained from an average of 404 gins per season from 1928 through 1933, the survey covering 91 percent of the gins and 98 percent of the production of the State. The varieties grown per county and per gin, the ginnings of different varieties, predominant varieties in different counties and geographic districts, the mixing of seed in ginning, renewal of seed supply, improvement of varieties, etc., are discussed.

Thirty-seven recognized varieties were reported from 1928 through 1933, 19 varieties being grown in one county in 1929. The number of varieties per gin most commonly reported was five. Less than 2 percent of the growers confined their efforts to the systematic production of one variety. From 1931 through 1933 the number of varieties decreased in seven counties and increased in one. The two varieties most extensively grown were Delta and Pine Land and Half and Half. The production of the Delta and Pine Land variety increased from 11.4 percent of the total production in 1928 to 35 percent in 1932. The production of Half and Half decreased from 46 to 23 percent of the total production. In 1928, 7.6 percent of the total cotton plantings were from pedigreed seed. The percentage in 1933 was two.

Soybean projects of the State agricultural experiment stations, 1937, compiled by H. M. STEECE (*U. S. Dept. Agr., Off. Expt. Stas., 1937, pp. [2]+17*).—Superseding a similar publication (E. S. R., 75, p. 195), this lists by experiment stations the titles, leadership, and station departments of 245 currently

active research projects concerned with the production and utilization of soybeans.

Cane growth studies: The effect of sunlight on the utilization of nitrogen and potash by H 109 cane, R. J. BORDEN (*Hawaii. Planters' Rec. [Hawaii. Sugar Planters' Sta.]*, 41 (1937), No. 1, pp. 3-5).—In further growth studies with sugarcane (E. S. R., 75, p. 774), H 109 cane was grown in pots in Manoa soil (low in available nitrogen and potassium) treated with ample phosphate and supplied with nitrogen fertilizer at rates of 0, 150, 225, and 300 lb. per acre (with 400 lb. of potash per acre), and 0, 200, 300, and 400 lb. of potash fertilizer (with 300 lb. of nitrogen). One series was grown continuously in full sunlight, a second received full sunlight from sunrise to midday only, and a third was exposed to full sunlight from midday to sunset only.

Differences between morning and afternoon sun were not demonstrated in the final results, although during the test indications were that plants receiving afternoon sun made more growth. Dry weights were greater from cane grown in full sunlight. When no nitrogen was supplied all growth was very poor and no apparent differences in dry weights were noted. While decided responses came from the first increments of nitrogen and of potassium, an apparent inability of plants grown under a reduced amount of light to use effectively the heavier applications of plant food was shown clearly. Plants grown in full sunlight appeared to be less succulent than either series grown under reduced light, and the percentage of moisture in the plants at harvest was influenced by fertilizer treatment, being the higher in canes receiving larger quantities of nitrogen and of potash. Practical suggestions from the results include the adjustment of fertilizer applications with respect to the expected and prevalent sunlight conditions that would be likely to affect each crop.

Sweet potato production in Louisiana, J. C. MILLER and W. D. KIMBROUGH (*Louisiana Sta. Bul.* 281 (1936), pp. 23, figs. 2).—Seed and planting practices indicated from station experiments with sweetpotatoes include choice of the Porto Rico variety; treatment with corrosive sublimate solution of selected seed before bedding at the rate of from 6 to 8 bu. to provide plants for 1 acre; bedding in rows in the open for the main crop in south Louisiana; using vine cuttings rather than pulling slips when beds are in field rows; and setting plants, June 1-15, 12 in. apart in ridged rows from 12 to 14 in. high and from 3.5 to 4 ft. apart on sandy and silt loam soils receiving from 400 to 600 lb. per acre of 4-12-4 or 4-8-4 fertilizer. The crop should not be planted on the same land oftener than every other year. Two shallow cultivations are usually needed to control weeds.

Sweetpotatoes should be harvested before frost, usually best in October, avoiding bruising, grading the marketable potatoes carefully, and placing them in storage crates. In curing, sweetpotatoes should be kept at from 80° to 85° F. for from 10 to 20 days just after digging and from 50° to 60° after curing. In south Louisiana, artificial heat is not needed for roots harvested in October.

Distribution of the varieties and classes of wheat in the United States in 1934, J. A. CLARK and K. S. QUISENBERRY (*U. S. Dept. Agr. Circ.* 424 (1937), pp. 68, figs. 65).—The distribution and acreages of classes and varieties of wheat are shown from surveys for the crop year 1934, based largely on the harvested wheat-acreage reported for the special agricultural census of 1935, and are compared with the distribution in 1919, 1924, and 1929 (E. S. R., 70, p. 771). The distribution of the more important wheats is shown on varietal maps, and estimated acreages and percentages of the total wheat acreage occupied by each variety or class in 1919, 1924, 1929, and 1934 are tabulated by States and for the United States.

The total acreage (harvested acreage in all but 12 drought States) in the United States in 1934 in round numbers was 61 million acres, somewhat higher than the 1924-33 average of slightly over 57 million acres, and compared with 51 million acres in 1924 and 62 million in 1929. In general, increases in acreages were reported in Ohio, Arkansas, and certain southeastern States, decreases in several Middle Atlantic States, increases in Arizona, Colorado, Kansas, Minnesota, and Texas, and decreases in Oklahoma, Oregon, and States in the northern Great Plains. Ceres, Blackhull, Fultz, Nebraska No. 60, Albit, Dawson, and Fulhio made the greatest increases in percentage of acreage during the 1929-34 period, and Marquis, miscellaneous durums, Pentad, Kanred, Turkey, and Goldcoin made the greatest decreases. Varieties grown on more than 1,000,000 acres listed in the order of importance included Turkey, Marquis, Blackhull, Ceres, Kanred, Fultz, Fulcaster, and Trumbull.

Chemical, milling, and baking results for wheat varieties grown in the cooperative varietal experiments in the western region in 1934. C. C. FIFIELD, C. E. BODE, B. B. BAYLES, J. F. HAYES, R. WEAVER, and A. CHRISTIE (*U. S. Dept. Agr., Bur. Plant Indus., 1936, pp. [1]+41, fig. 1*).—Representative samples of wheat varieties produced in cooperation with State experiment stations in field plats and uniform nurseries in the western region in 1934 were tested for milling value and for quality as determined by chemical and baking methods (bread, cake, and cookies), and, in addition, the dough-ball time and index of particle size were determined for part of the samples.

At several stations only a small range of protein content occurred between varieties, while at others, notably Bozeman, Mont., and Union, Oreg., the range was about 6.5 percent. In general, soft wheats were lower than those with hard vitreous grain. Carotene values were very high for the club wheat varieties, being for the most part in excess of 3 p. p. m. The dough-ball time test showed considerable variation, but generally the club and soft winter wheats had the lowest values, the higher values being associated with the varieties having hard vitreous kernels. The wheats of a vitreous type, such as hard white, hard red winter, and hard red spring, had low indices of particle size, which appear to be associated with grain producing a coarse, granular flour. The soft white and club wheats, normally producing flours soft and velvety to feel, had high indices of particle size.

With respect to the bread-baking test, Baart, Ridit, Kharkof, White Federation, and Turkey generally were highest in quality, while Golden, Rex, Fortyfold, Albit, Triplet, Federation, and Pacific Bluestem were low. The club wheats Hybrid 128, Jenkin, Albit, Hymar, and Union were of inferior quality and considered poorly adapted for bread. Marquis, grown in the Pacific Northwest, was usually of inferior strength. In general, the varieties having high baking values indicative of bread baking strength were also high in protein content. Certain exceptions are noted.

In the cake test, Baart, Hybrid 128, Golden, Triplet, Albit, Fortyfold, Irwin Dicklow, Onas, Pacific Bluestem, and Jenkin were high in quality, while the hard or more vitreous wheat selections as White Federation, Hard Federation \times Dicklow, Florence \times Marquis, Kharkof, Ridit, Ceres, and Marquis were inferior. Varieties giving the best results in the cookie test were Albit, Rex, Jenkin, Onas, Hybrid 128, Golden, Irwin Dicklow, and Federation. The hard wheats made very poor cookies.

Yams for Hawaiian gardens, II. E. L. CAUM (*Hawaii, Planters' Rec. [Hawaii. Sugar Planters' Sta.] 41 (1937), No. 1, pp. 13-18, figs. 5*).—The merits of certain varieties of Chinese yam (*Dioscorea batatas*) are set forth, supplemental to an earlier note (E. S. R., 75, p. 776).

Seed inspection in Kentucky, 1934-1936, W. A. PRICE, E. C. VAUGHN, E. DEEN, J. TAYLOR, and A. MARRS (*Kentucky Sta. Regulat. Ser. No. 11* (1937), pp. 18).—The purity, germination, and presence of excessive quantities of noxious weed seed are reported for 345 official samples of agricultural seed obtained July 1, 1934-June 30, 1936.

Summary of results of seed and legume inoculant inspection for 1936, J. G. FISKE (*New Jersey Stat. Bul. 623* (1937), pp. 23).—The dealers in New Jersey from whom the 1,933 official samples of crop and vegetable seed and seed mixtures were collected in 1936 are listed with compliances and violations indicated; and the crops, inoculation, and number of organisms are shown for 46 official samples of legume inoculants.

HORTICULTURE

[Horticultural investigations conducted by the New Jersey Stations] (*New Jersey Stat. Rpt. 1936*, pp. 37-40, 53-69).—Among studies for which findings are reported are those dealing with cranberry fertilizers and harvesting, compatibility of pyrethrum insecticides with bordeaux mixture, fertilizers for blueberries, breeding of peaches, resistance of peaches to low temperature, rootstocks for peaches, effects of mineral deficiencies on peach trees, nutrient deficiency effects on the apple, breeding the apple, growth status of apple trees, strawberry breeding, strawberry culture and varieties, tomato and asparagus breeding, vegetable varieties, relation of lime and organic matter to tomato yields, varietal response of lima beans to nitrogen, lime requirements of vegetables, relation of sodium to calcium in the growth of the tomato, temperature requirements of tomato varieties, cause of bud-drop in gardenias, culture of roses, chrysanthemums, carnations, and snapdragons, the testing of chrysanthemums, phlox, iris, and dahlias, the relation of spray schedules to spray residue removal, and the development of more economical and effective methods of removing toxic residues from fruits.

[Horticultural investigations by the Wisconsin Station] (*Wisconsin Sta. Bul. 438* (1937), pp. 72, 73, 100-103).—Brief popular reports are presented on pea-breeding investigations and the resulting varieties, by E. J. Delwiche; lima beans and tomatoes adapted to Wisconsin, by O. B. Combs; the protection of grapes by covering with soil, and varieties of black raspberries, both by J. G. Moore; mulching of strawberry beds, by R. H. Roberts; and culture of orchards, by L. Langford and Roberts.

Minor elements affecting horticultural crops, H. HILL (*Sci. Agr.*, 17 (1936), No. 3, pp. 148-153, figs. 7; *Fr. abs.*, p. 153).—In the case of turnips grown in sand culture, plants receiving no boron showed definite signs of disorder at the end of 6 weeks. Root growth was limited, and all roots became affected with hollow heart. To develop large healthy roots, 1 to 1.5 p. p. m. of boron were required. It was found that neither copper nor zinc could replace boron in the nutrition of the turnip. In the case of the tomato and potato, definite growth disturbances were observed where boron was absent from the nutritive solution. Blotchy-cork disease of apples growing in pots was controlled by boron. In work with tomatoes, chrysanthemums, strawberries, and turnips in sand cultures, copper was found to be an essential nutrient. In the absence of manganese, potato plants were stunted and their yields reduced. Zinc, uranium, and strontium were supplied to tomatoes in concentrations ranging from 0.01 to 0.5 p. p. m. without external results.

Propagation response from root cuttings planted with the proximal end projecting above the medium, W. H. UPSHALL (*Sci. Agr.*, 17 (1936), No. 3, pp.

146, 147, fig. 1; *Fr. abs.*, p. 147).—Not only was there a much better rooting response when the top or proximal ends of cuttings were planted so that 0.6 cm projected above the rooting medium, but top growth was also much more rapid and the cuttings that failed to develop did not rot as quickly as those which were completely covered. The improved rooting is ascribed either to the effects of light or aeration.

Evaporation studies.—I, A survey of evaporation and light values in greenhouses, J. D. WILSON (*Ohio Sta. Bimo. Bul.* 186 (1937), pp. 87–97, figs. 3).—For the purpose of making a general survey of existing climatic conditions, atmometer readings were taken over a 12-mo. period in 31 widely distributed greenhouses varying greatly in construction, crops grown, etc. Evaporation was found greatest in July and at a low point in October, November, and December. Light values were low in December and January. Shading in summer reduced evaporation from the black atmometers by 22 percent and the intensity of light by 38 percent. Forcing heated air through the greenhouse increased evaporation approximately 50 percent above that of houses warmed in the ordinary manner.

The metabolism of fruit and vegetables in relation to their preservation, M. COPESABOW (*Jour. Pomol. and Hort. Sci.*, 14 (1936), No. 1, pp. 9–18).—Maleic acid was found to inhibit ripening and germinating processes and parasitic activity in a variety of fruits and in the potato. The acid was more effective in an inert ethereal oil than in an aqueous medium. Ethereal extracts of apples, freed from the solvent and dissolved in inert esters, exert an inhibiting effect similar to that of maleic acid upon embryonic development and respiration of fruits and potatoes. The author considers it likely that maleic acid is identical with the natural inhibitor “blastokolin”, and that the transition of this inhibitor into the accelerator is represented by the degradation of maleic acid into ethylene.

The vegetable gardener's how book, C. C. SHERLOCK (*New York: Macmillan Co.*, 1937, pp. XIX+286, [pls. 28]).—With subject matter arranged alphabetically by plants, general information is presented on culture, varieties, harvesting, control of pests, etc.

Some observations on individual asparagus plant records, O. J. ROSS (*Sci. Agr.*, 17 (1936), No. 3, pp. 144, 145; *Fr. abs.*, p. 145).—Individual plant records taken by the Horticultural Experiment Station, Vineland, Ontario, on three lots of Mary Washington asparagus plants showed a range from 4 to 40 marketable stalks per plant per season. Counting all plants with less than 10 stalks as unprofitable, it was estimated that 39 percent of the plants were not in this class. There was a tendency for low or high production to be maintained through the years, and a high positive correlation was established between early yields and total yields. Crosses were made between high-yielding male and female plants in the hope of developing high-yielding progeny.

Garden beans, C. G. VINSON (*Missouri Sta. Circ.* 195 (1937), pp. 11, fig. 1).—General information is presented on varieties, cultural requirements, control of insect and disease pests, storing of seed, and other matters.

Analytical observations on the changes of pectic substances and sugars in celery during cold storage, R. H. WHITE-STEVENS (*Sci. Agr.*, 17 (1936), No. 3, pp. 128–136; *Fr. abs.*, p. 136).—Studies of Golden Self Blanching celery stored at 32° F. failed to show any well-defined correlation between pectic hydrolysis and storage maturity apart from the cytolytic effects of pathogenes. Sucrose increased markedly in the early part of the storage period, ultimately declining

with a simultaneous increase in hexose, which in turn reached a maximum and then declined. Basing food value on sugar content, it was suggested that, in general, the optimum storage period for celery at 32° is between 60 and 100 days, with a possibility that factors such as variety, cultural treatment, and harvesting may influence the sugar changes markedly.

The garden of gourds, L. H. BAILEY (*New York: Macmillan Co., 1937, pp. [4] + 134, pls. 42*).—General information is presented on the classification of gourds, desirable and distinguishing characteristics, and culture.

Varieties of cabbage lettuce and their classification, P. W. BRIAN (*Jour. Pomol. and Hort. Sci., 14 (1936), No. 1, pp. 26-38*).—Discussing some of the distinguishing characteristics of the various head lettuce varieties grown in England, the author presents a preliminary classification of varieties.

Breeding tip-burn resistant lettuce, I. C. HOFFMAN (*Ohio Veg. Growers Assoc. Proc., 21 (1936), pp. 96-98*).—Selections from commercial and other strains of Grand Rapids lettuce, growing in the greenhouses of the Ohio Experiment Station, yielded certain plants free from tipburn. Progenies raised from these plants were much more resistant than commercial stock, and those of one line, No. 7, were free from tipburn. Under adverse summer conditions in the field all strains developed some tipburn, but No. 7 was again selected for propagation because of superior qualities.

Irrigation experiments with the Early Grano onion, A. S. CURREY (*New Mexico Sta. Bul. 245 (1937), pp. 39, figs. 12*).—Beginning about 6 weeks after transplanting, five different irrigation treatments were compared on quadruplicated plats. A summation of 5 years' work showed the highest average yield and the highest average percentage of No. 1 bulbs on the plants receiving the most frequent irrigation and the greatest amount of water. At the same time the treatment with the smallest number of irrigations and the smallest amount of water returned the lowest yields and the lowest percentage of No. 1 bulbs. It was not possible to associate premature seedstalk formation with any irrigation treatment, but there was some evidence that time of maturity is related to the water supply. The onions on the most abundantly irrigated plats tended to mature last and those on the least irrigated plats first.

Soil-moisture determinations showed the greatest use of water in late May and early June. A tight layer of clay about 5 or 6 ft. below the surface interfered with the downward movement of water and resulted in some difficulty in establishing definite water tables.

Storage studies with onions from the different treatments gave indication that the most frequently irrigated bulbs kept somewhat better and suffered less weight loss in storage. In 1934, a season favorable to the development of thrips and pink root rot, it was impossible to establish the relationship between extent of injury and the differential treatments.

Some factors in tomato fruit setting, including experiments with artificial light, F. S. HOWLETT (*Ohio Veg. Growers Assoc. Proc., 21 (1936), pp. 79-86*).—Discussing the physiology of flower formation and pollination in tomato, the author reports the successful use of supplemental light in the greenhouses of the Ohio Experiment Station for increasing the number of flowers to attain full bloom and the set of fruit during the dark days of midwinter.

The necessity of minor elements for the growth of tomatoes in a poor soil, J. S. McHARGUE and R. K. CALFEE (*Amer. Fert., 85 (1936), No. 6, p. 24*).—Results of studies at the Kentucky Experiment Station showed very marked benefits from the addition of small quantities of certain so-called minor elements to soil cultures with tomatoes as test plants. The fruit of plants

receiving the minor elements in addition to the usual fertilizers was distinctly superior.

Inspection, certification, and transportation of nursery stock in Kentucky, with a brief report for the year ended June 30, 1936, W. A. PRICE and H. G. TILSON (*Kentucky Sta. Regulat. Ser. Bul. 12 (1937), pp. 11*).—As indicated in the title, this paper contains general information on the carrying out of the Kentucky nursery inspection law.

Hardy fruit growing, F. KEEBLE and A. N. RAWES (*London: Macmillan & Co., 1936, pp. XI+334 [pls. 21], figs. 3*).—From the English viewpoint, general information is presented on fruit culture, supplemented with sufficient of the principles of growth, reproduction, and nutrition, to give an explanation for the reasons underlying practice.

Pioneering with fruits and berries, G. D. AIKEN (*Brattleboro, Vt.: Stephen Daye Press, [1936], pp. XII+94, pls. [24]*).—General information is presented on the growing of various tree and small fruits and asparagus.

Tree wound dressings, H. C. YOUNG and P. E. TILFORD (*Ohio Sta. Bimo. Bul. 186 (1937), pp. 83-87, figs. 2*).—Studies of wounds made on healthy ash, American elm, hickory, oak, Carolina poplar, red maple, and wild cherry trees showed asphalt paint to be a desirable wound dressing, not only in promoting healing but also in decreasing the amount of subsequent decay which appeared to some extent in all treatments. Bordeaux paints plus various amendments added to darken the wound tissues proved unsatisfactory. Although 3.5 yr. elapsed before making final examinations, the authors feel that more time should pass before reaching final judgments on the effects of the treatments.

Variation in the "Paradise" apple rootstocks: A study of some leaf and shoot characters in four races, H. M. TYDEMAN (*Jour. Pomol. and Hort. Sci., 14 (1936), No. 1, pp. 19-25*).—Detailed studies made at the East Malling Research Station of certain leaf and shoot characters of 1-yr. vegetative shoots arising from vigorous 7-year-old stools of four races, viz, Malling II, a selected clon of Malling II, Malling IX, and a selected clon of Malling IX, failed to show any appreciable difference between the original stocks and the selections therefrom. So far as it was possible to determine, reselection from a single individual plant had neither decreased the variability nor altered markedly the expression of the characters in either of the rootstocks.

The daily rate of photosynthesis, during the growing season of 1935, of a young apple tree of bearing age, A. J. HEINICKE and N. F. CHILDERS (*[New York] Cornell Sta. Mem. 201 (1937), pp. 52, figs. 10*).—The enclosure of an entire vigorous young McIntosh apple tree in an assimilation chamber carefully sealed to prevent uncontrolled movement of air and cooled with a refrigeration unit under thermostatic control permitted the study of the carbon dioxide content of the incoming and outgoing air, the difference indicating the photosynthetic activity of the tree. Light intensity was measured with an Eppley pyrheliometer located about 1 mile distant from the experiment but so equipped that automatic records were taken every 3 sec.

The results indicated that there are marked fluctuations in the rate of food manufacture from day to day, with light the most important limiting factor. Leaves well exposed to light and abundantly supplied with water and soil nutrients were evidently capable of carrying on photosynthesis over a wide range of temperatures, as low as just above freezing. The rate of respiration was evidently influenced more by temperature than was the rate of photosynthesis. The higher temperatures which frequently accompanied the highest light intensities increased the rate of respiration and thus tended to offset the influences of favorable light. The closing of the stomata, occur-

ring normally in the afternoon, did not greatly reduce the rate of apparent photosynthesis of the entire tree.

In conclusion the authors suggest that although daily fluctuations of apparent photosynthesis must exert an effect on the chemical balances of the tissues of the trees, there is a question of just how rapidly growth and other metabolic processes adjust themselves to the internal chemical environment. It is believed that in most cases the adjustment is so gradual that the responses are determined to a greater extent by photosynthetic activity over periods of a week or so than by daily fluctuations.

The effect of sodium nitrate and water applications to apple trees suffering from drouth on some chemical constituents of the fruit, H. H. PLAGGE (*Iowa Acad. Sci. Proc.*, 42 (1935), pp. 77-79).—In the dry summer of 1931, Golden Delicious apple trees growing in the orchards of the Iowa Experiment Station were given, beginning August 12, five weekly irrigations each equivalent to a 2.8 acre-in. application of water. In addition, one irrigated and one nonirrigated tree were sprayed with 8 lb. of nitrate of soda. Studies of the fruits showed that irrigating did not materially change the nitrogen content or make the fruit more susceptible to soggy break-down. Sucrose and total sugar content were increased by irrigation. Little difference was recorded between the fruits of the irrigated trees and of the trees irrigated and also receiving nitrogen, either in sugars or nitrogen, but the nitrated nonirrigated fruits were very high in nitrogen, particularly of the noncolloidal type. However, susceptibility to soggy break-down was not increased in this case.

Influence of orchard soil management on tree growth, C. W. ELLENWOOD (*Ohio Sta. Bimo. Bul.* 185 (1937), pp. 56-58).—Summarizing 22 years' records of the growth of Stayman Winesap and Delicious apple trees grown under two systems of culture, mulched bluegrass and cover crop tillage, there were indicated very slight differences between the two. During the period the total yield of Stayman Winesap was a little greater on the cover crop plat, while the opposite was true for Delicious. The fruits of Stayman Winesap were significantly larger and those of Delicious were somewhat larger on the grass mulch plats. It is suggested that the higher moisture content of the soil in the mulch plats in years of less than normal rainfall is likely responsible for the greater tree growth and the larger total yields. Color of fruit was not materially affected by culture.

Progress report on the investigation of corky core in apples, L. C. YOUNG and C. F. BAILEY (*Sci. Agr.*, 17 (1936), No. 3, pp. 115-127, figs. 2; *Fr. abs.*, p. 137).—Attempts by the Dominion Experimental Station, Fredericton, New Brunswick, to control corky core by treating trees in different ways with boron, zinc, and magnesium were successful only in the case of boron. Since the amount of corky core varied greatly from year to year even to the point that a tree might be severely affected one year and free the next, continued observations are necessary. The repeated borings of trees which are necessary in the injection treatment are injurious, and the application of boron as a spray is suggested as a promising substitute method. Soil applications were also under study. Anatomical examinations of roots failed to show any correlation between the plugging of the vascular ray cells and the occurrence of corky core. There was, however, a tendency for a concentration of the larger roots at greater depths in nonaffected orchards where corky core was prevalent.

Comparative costs and efficiency of stationary vs. portable spraying, C. L. BURKHOLDER (*Indiana Sta. Bul.* 415 (1936), pp. 20, figs. 10).—A stationary spray plant covering 45 acres, installed in 1930 in the Purdue orchard at Bed-

ford, and portable equipment used in the same orchard were accurately compared as to costs. The data indicated that the entire cost of the stationary plant could be paid in 5 yr. by the savings in the cost of applying the sprays. In addition, the permanent equipment was in good condition at the close of 6 yr., whereas the portable outfits were practically worn out. With special equipment, such as long-distance guns, stationary equipment gave satisfactory control of codling moths in the tops of trees. Before securing this additional equipment, the station found that the portable outfits were more effective in the tops of the trees. The control of apple scab was equally good with both types of spraying. The details in the planning, construction, and operation of the stationary plant are presented.

Spray residue work in Missouri, C. G. VINSON (*Missouri Sta. Bul.* 382 (1937), pp. 15).—Experiments conducted with apples sprayed with different schedules and different materials showed that the type of material used has an important influence on the success of washing. Certain oils and proprietary materials, for example, greatly increased the difficulty of removing spray residues, and, on the other hand, the inclusion of lime in the spray facilitated the removal of both lead and arsenicals. Water alone in the wash section of an underbrush flood-type machine reduced the lead content of the spray residue by as much as 50 percent when the original load did not exceed 0.05 grain of lead per pound of fruit. Where oil had been used with each cover spray, 1.2 percent hydrochloric acid plus 4 lb. of dry Vatsol to 100 gal. did not reduce the lead content from 0.1 to within the tolerance limits, the temperature being 65° F. and the exposure 30 sec. Heating the bath to from 100° to 110° made the residue reduction possible. The need of thorough rinsing of fruit with fresh water was indicated. It was possible to reduce the arsenic to a satisfactory extent and yet leave an appreciable residue of lead. Zinc was definitely an interfering substance in the determination of lead by the diphenylthiocarbazone method.

Cold storage problems with apples, M. B. DAVIS and D. S. BLAIR (*Sci. Agr.*, 17 (1936), No. 3, pp. 105-114; fig. 1; *Fr. abs.*, p. 114).—Stating that maturity plays an important role in the keeping behavior of apples, the authors report that with Fameuse and McIntosh apples the ground-color and iodine-starch tests have proved the most valuable indexes to maturity. Loss from storage rots was largely eliminated by careful handling and the maintenance of correct temperatures. There was some indication that fruits grown under high nitrogen conditions are more subject to decay than those from low nitrogen areas. Shrinkage loss in storage was largely obviated by a combination of low temperature and high relative humidity. As to apple scald, maturity at time of storing appeared, in the case of McIntosh and Fameuse, to be more important than any other factor. With reference to gas storage, McIntosh apples stored at 40° F. under 7.5 percent carbon dioxide concentration when wrapped in oiled paper kept with less shrinkage than comparable fruits held at 32° in natural atmospheres.

Influence of packing and handling methods on condition of apples barreled for export, P. L. HARDING, J. M. LUTZ, and D. H. ROSE (*U. S. Dept. Agr. Tech. Bul.* 559 (1937), pp. 26. figs. 7).—Stating that barreled apples from the United States often reach European markets in unsatisfactory condition, the authors discuss the results of investigations of various methods of packing apples to minimize losses from injury. One shipment of York Imperials originating in Hancock, Md., was followed through to the English destination. It was established that shaking the barrel 2 or 3 times while filling, racking 15 times when nearly full with the plug, or follower, in place, and filling to about three-fourths of an inch above the top of the staves was sufficient to prevent appre-

ciable settling during transit. Filling the barrel more than three-fourths of an inch above the top of the staves caused an undue amount of bruising and skin breaks, especially when the barrels had been shaken and racked as recommended. Overfilling could not be substituted for adequate shaking and racking in the prevention of slackness. Four varieties, namely, York Imperial, Rome Beauty, Jonathan, and Grimes Golden, were utilized in the experiments, and specific information is presented for each. The higher percentages of bruising noted on Grimes Golden are thought to be due to the fact that the light golden skin failed to mask bruises. From 12 to 14 percent of the skin breaks in barreled apples were found to be due to stem punctures, but no correlation was apparent between the number of stem punctures and the amount of shaking or racking or the height of the pack.

Protection of apples and pears in transit from the Pacific Northwest during the winter months, E. D. MALLISON, E. A. GORMAN, JR., and W. V. HUKILL (*U. S. Dept. Agr. Tech. Bul.* 550 (1937), pp. 55, figs. 19).—Experiments carried on over a period of several years and mostly during the winter months of December, January, and February showed the need for improved methods of protecting fruit and, to some extent, how to accomplish them. The use of wind-activated fans to increase air circulation served to create more nearly uniform temperature conditions in the cars. In order to prevent dangerously low temperatures near the floor, it was found that heaters should be placed in each bunker. The operation of two heaters according to the temperature needs not only prevented freezing injury but avoided excessively high temperatures in the top layers. The opening of ventilators during periods of high outside temperature was found unnecessary with apples and pears loaded at from 30° to 35° F. With outside temperatures of 20° or lower, prewarming of cars and the retention of heat during loading was found desirable to prevent freezing. Ice in the bunkers not only did not prevent freezing but caused the fruits to freeze more quickly. Insulating materials placed around the fruit actually increased the hazard due to interference with air circulation. Wet sawdust placed under the floor racks and on the bunker floors proved helpful by virtue of the latent heat of fusion when outside temperatures were not below 0° for prolonged periods. Heaters which depended on the natural circulation of air alone did not give uniform and optimum storage temperatures. It was observed that the efficiency of heater service depending on charcoal heaters may be greatly improved by inside control, that is, by releasing the heat inside the cars when the minimum temperature in the car drops to slightly above the freezing point of the fruit.

Stem-end shrivel of Packham's Triumph pear, H. BROADFOOT and E. C. WHITTAKER (*Agr. Gaz. N. S. Wales*, 47 (1936), No. 11, pp. 635, 636, fig. 1).—This condition was found to be influenced mainly by the developmental stage of the fruit when picked. The best stage for harvesting was when the fruit showed a decided yellowish tinge and a pressure test reading of about 12 lb.

Pollination studies with plums, II [trans. title], C. F. RUDLOFF and H. SCHANDEL (*Gartenbauwissenschaft*, 10 (1937), No. 5-6, pp. 669-687).—Of 65 varieties under observation in this continued study (E. S. R., 70, p. 626), 39 were definitely self-unfruitful, 4 partially unfruitful, and 22 clearly self-fruitful. Compatible pollinizers are suggested for the various varieties with no evidence that cross-pollination increased the yield of self-fruitful plums. In the case of varieties with poorly germinating pollen, percentage of germination was increased by adding stigmatic tissues to the culture. Supplemental stigmatic tissue of the same variety was more effective with pollens of the self-fruitful than of the self-unfruitful kinds.

Nitrogen and carbohydrate content of the strawberry plant: Seasonal changes and the effects of fertilizers, J. H. LONG and A. E. MURNEEK (*Missouri Sta. Res. Bul.* 252 (1937), pp. 52, figs. 27).—Aroma strawberry plants, selected as the first runners to develop from mother plants set out in early April in fertile propagating soils, were sampled at different periods throughout the growth cycle. The dry weight of the plants was found to increase rapidly during autumn and reach a maximum at the approximate stage of greatest leaf development. A decrease began with the dormant season and continued on through flowering, fruiting, and runner formation. Total nitrogen reached the maximum in November and from then on decreased slowly through the dormant season and rather rapidly through the fruiting and runner-production periods. At the time of the greatest development of leaves in late autumn, 70 percent of the nitrogen was in the leaves, but in winter from 30 to 40 percent could be found in the roots. Young, developing leaves and reproductive organs drew heavily on the stored nitrogen, so that roots and stems were almost completely free by midsummer. There was noted a rapid flow toward the stems and roots of soluble carbohydrates during summer and autumn, and particularly during the period of leaf senescence. As a result, sugars attained a high concentration in the stems and roots during the dormant season. At the time of maximum foliar development, from 50 to 75 percent of the total sugar was in the leaves. Accumulation of sugar was accompanied by a decrease of starch and hemicellulose. Two seasonal maxima, February and November, and three minima, April, October, and January, were noted in starch accumulation.

Applications of nitrogen fertilizer, either organic or inorganic, did not alter greatly the seasonal variation in carbohydrate contents. Nitrogen fertilizer in all forms did increase the number of flowers. Spring application increased the leaf area and nitrogen concentration in all parts of the plant but had no material effect on fruit production. Only in the absence of adequate fall supply of nitrogen did spring applications influence fruit development, thus indicating the practical desirability of applying nitrogen in autumn. A minimum quantity of 0.12 g of nitrogen per plant in October is believed necessary to the production of a maximum number of flowers in the Aroma variety. Leaf measurements indicated that a minimum leaf area of 300 cm² during the period of flower-bud formation is essential for each Aroma budding plant.

Strawberry fertilizer studies in Maryland, W. E. WHITEHOUSE and A. L. SCHRADEE (*Maryland Sta. Bul.* 403 (1936), pp. 177–206, figs. 2).—Studies conducted with four varieties of strawberries grown on soils varying in character from loamy sands to heavy silt or clay loams indicated that the fertilizer treatment, both as to time of application and quantity and quality of materials, must be varied with the variety and with the type of soil. Before the strawberry plants were set, the average soil required a fertilizer containing quickly available nitrogen in order to develop adequate runner plants. Fertile soils, on the other hand, were often sufficiently provided with plant food to grow excellent stands without fertilizer. Certain varieties, such as Missionary, which produce runners freely, may be easily stimulated to an overproduction of young plants. With respect to yield, the response to fertilizers applied prior to planting was such as to suggest that on good quality soils it may be difficult to show significant increases from fertilizer use.

Late summer applications of fertilizer, on the contrary, usually gave good results, probably because of the increased growth and development of the plants which in turn enabled them to produce larger berries and mature them earlier. Late summer applications were more desirable and beneficial than applications in the spring of the first fruiting year. Top dressings in the

spring of the second season may, however, be expected to increase yields. There was apparently a close relationship between soil moisture and other environmental factors and the effects of fertilizer applied in the spring of the fruiting year. The evidence from the use of lime was such as to indicate that applications sufficient to satisfy the lime requirement of the soil had a detrimental effect on early runner formation. In very acid soils moderate applications of lime were beneficial.

Strawberries under neon light, J. W. M. ROODENBURG (*Jour. Roy. Hort. Soc.*, 61 (1936), No. 12, pp. 504-509, pls. 4, fig. 1).—Provided that irradiation of strawberry plants of the Deutsch Evern variety was begun in early October before naturally short days and low temperatures had induced a condition of rest, it was possible to continue the plants in a vegetative condition with abundant flower formation and early fruit. Otherwise, it was necessary to submit the plants to low temperature and begin forcing about New Year's Day.

Hybridization of the strawberry [trans. title], N. J. FEDOROWA (*Gartenbauwissenschaft*, 10 (1937), No. 5-6, Ref., pp. 106, 107).—The genus *Fragaria* is said to occupy a singular position in the plant kingdom because of its very high degree of polyploidy, exhibiting forms with as many as 98 somatic chromosomes, all based on an original haploid number of seven. Polyploidy is very frequent, and segregation into staminate, pistillate, and perfect-flowered forms occurs to an unusual degree. The perfect plants transmit no special sex tendency to their progeny, whereas the pistillate plants appear to consist of at least two genetic types, one of which yields staminate and pistillate progeny and the other pistillate and perfect-flowered progeny. Pistillate plants which in crossing with perfect or staminate plants yield perfect progeny must possess some weak male sex-determining factors.

Red fruit color was found dominant over white and was determined by a dominant gene. Everblooming was a recessive character controlled by a single recessive gene. A limited number of flower stalks was dominant over a larger number and was apparently determined by several dominant genes.

Four species, *F. vesca*, *F. grandiflora*, *F. elatior*, and *F. virginiana*, entered into the study.

Sanding cranberry bogs, C. S. BECKWITH (*New Jersey Stat. Circ.* 371 (1937), pp. 4).—General information is given on the present status of sanding cranberry bogs, on methods of applying sand, and on the potential benefits.

Results of manurial experiments on cacao at Marper, F. J. POUND and J. DE VERTEUIL (*Trop. Agr. [Trinidad]*, 13 (1936), No. 9, pp. 233-241).—Of various fertilizing materials, potassium sulfate applied at the rate of 300 lb. per acre proved most profitable. Superphosphate of lime yielded a reasonable profit, but the combination of potassium and phosphorus, although increasing yields, did not give profitable returns. Lime applied at the rate of 5 tons per acre increased yields by nearly 40 percent but was not profitable. Nitrogen gave no benefit at all and when used with either phosphorus or potassium tended to decrease rather than increase yields.

The cryoscopic determination of the osmotic value of citrus leaf sap, F. F. HALMA (*Gartenbauwissenschaft*, 10 (1937), No. 5-6, pp. 659-668, figs. 2).—From this study, conducted by the California Experiment Station, on different methods of killing tissues, expressing sap, and recording the freezing point depression thereof, the author suggests (1) the killing of leaves in boiling water for 30 min., a procedure which rendered the tissues more stable under storage conditions than freezing with solid carbon dioxide and was more convenient and less expensive; (2) expressing the sap with a powerful vise which requires less time than with a hydraulic press; and (3) the use of a micro-

cryoscope which required only 2 cc of sap for an accurate reading. With all three species used, namely, lemon, orange, and grapefruit, the amount of sap obtained from the frozen material was generally greater than that secured from heated tissues.

Growth and water losses in citrus as affected by soil temperature, A. R. C. HAAS (*Calif. Citrogr.*, 21 (1936), No. 12, pp. 467, 479, fig. 1).—Observations by the California Experiment Station, Riverside, on rooted leafy twig cuttings of Valencia oranges placed in soil tanks maintained at 19°, 23°, 27°, 31°, and 35° C. showed the temperature range of from 23° to 31° C. (73.4° and 87.8° F.) most favorable for growth. In transpiration studies with rooted cuttings of lemon and grapefruit the water losses per unit of leaf area in the lemon increased with increasing soil temperature up to 31° C. In the case of grapefruit, the maximum was reached at 27°.

Report on duty of water investigations on citrus cultivation at Gan Moshe, near Rishon le Tsiyon, during the years 1931–32–33, J. DAWSON SHEPHERD, M. J. GOLDSCHMIDT, and J. D. OPPENHEIM (*Jerusalem: Palestine Dept. Develpmt.*, [1936], pp. [5]+28, [figs. 10]).—Evidence is presented in favor of moderate applications of irrigation water, with indications that unnecessarily large amounts of water have been used in the citrus-growing industry in Palestine. Among advantages of moderate irrigations were a wider spreading root system, better aeration of the soil, and an actual saving in the cost of production.

Use of soil-moisture and fruit-growth records for checking irrigation practices in citrus orchards, C. A. TAYLOR and J. R. FURR (*U. S. Dept. Agr. Circ.* 426 (1937), pp. 24, figs. 14).—Designed to serve as a guide to citrus growers who need a more accurate control of soil moisture, this paper presents information on soil-moisture control; amount of moisture readily available to trees, typical orchard records, the use of fruit-growth and soil-moisture records, and procedure and equipment. It is pointed out that soil samples taken in the zones of soil most thoroughly permeated by feeder roots give the first indication of moisture exhaustion. Details are presented on the method of checking soil moisture in each furrow or border to determine penetration while the water is actually flowing. Fruit measurements before and after irrigation were found to indicate any unusual need of water in the tree and enable the grower to determine the satisfactory interval between irrigations.

Notes on colorimetric tests for citrus species, R. H. MARLOTH (*Jour. Pomol. and Hort. Sci.*, 14 (1936), No. 1, pp. 1–8).—Presenting the results secured with four reagents, viz, Almen, ammonium molybdate, titanous chloride, and ferric chloride used with aqueous extracts of ground dried bark, dried roots, and dried leaves of several different forms of citrus, the author reports that samples belonging to one species such as the sweet orange often showed great variation, chiefly in color or shade, with certain reagents. Color reactions of hybrids showed no correlation with the reaction obtained with their parents. The conclusion is reached that not until the actual source and cause of color reactions is determined will these identification methods become absolutely reliable.

Is whitewashing to prevent sunburn on frozen citrus trees a safe practice? H. J. WEBBER (*Calif. Citrogr.*, 22 (1937), No. 5, pp. 185, 214, fig. 1).—In discussing past observations following freezes, the author points out that the evidence available on the effects of whitewashing frozen citrus trees is too incomplete and conflicting to permit the deduction of conclusions and the formulation of definite recommendations. There was evidence in some cases that whitewashing may be more harmful than beneficial.

The relative penetrability of various tissues of the orange and the banana to ethylene, D. A. HERBERT and L. J. LYNCH (*Roy. Soc. Queensland Proc.*, 46 (1934), pp. 72-79, pl. 1).—The diffusion of ethylene through the epicarp, mesocarp, and endocarp of orange and banana fruits was studied, using *Stellaria media* as a test plant. It is concluded that the differences in ripening of these fruits in an atmosphere containing ethylene are not due to a barrier against diffusion into the orange pulp, since the mesocarp of the banana offered approximately the same resistance as that of the orange.

Storage temperatures for shortening the rest period of gladiolus corms, F. E. DENNY (*Contrib. Boyce Thompson Inst.*, 8 (1936), No. 2, pp. 137-140).—Using Nos. 1 and 2 sized corms of several varieties, the author found that with lots stored at room temperature for 10 days after harvest 3° and 10° C. were much more effective in causing early germination than were higher temperatures. Except for the varieties Mrs. F. C. Peters and Mrs. Frank Pendleton, which required 6 weeks, a period of 3 weeks at these lower temperatures hastened germination. When the corms were allowed to stand until 52 days after harvest, the effects of storage temperature were different. Low temperature caused earlier germination in certain varieties, high temperature in others, and in two varieties, Mr. W. H. Phipps and Giant Nymph, 6 weeks' storage produced similar results both at 3° and 35°.

Longevity of pollen of *Lilium* and hybrid *Amaryllis*, N. E. PFEIFFER (*Contrib. Boyce Thompson Inst.*, 8 (1936), No. 2, pp. 141-150).—As a result of investigations with four species of *Lilium* and one hybrid *Amaryllis*, the author suggests two methods of conserving viability—(1) storage in relative humidities of 35, 50, and 65 percent at 10° C. and (2) storage in gelatin capsules without humidity control at -5° for *Lilium* and -11° for *Amaryllis*. With regard to relative humidity, the various species of lilies appeared to have rather specific optima, 35 percent for *L. auratum*, 50 percent for *L. speciosum*, and 65 percent for *L. longiflorum*.

Results of studies with poinsettias grown in sand, R. B. FARNHAM (*Florists' Rev.*, 78 (1936), No. 2007, pp. 19, 20, fig. 1).—At the New Jersey Experiment Stations, poinsettia plants started from cuttings on June 6 and later transferred to 4-in. pots were grown in a series of sand cultures involving a complete nutrient solution used at approximately ½-, 1-, and 2-atmosphere concentrations. The plants receiving the low concentration solution produced a large succulent growth, and when transferred at Christmas time to room conditions lost nearly all their leaves within 2 weeks. The smallest plants, 2-atm. concentration, held all their leaves for more than 4 weeks. During the test period, no additional nutrients were supplied. In conclusion, the author suggests that to produce poinsettias of good keeping quality the plants should be held on the dry side by infrequent small applications of water.

Pyrethrum (*Pyrethrum cinerariaefolium* Trev.), P. TOPALOV (TOPALOFF) (*Pyrethrum* (*Pyrethrum cinerariaefolium* Trev.). *Sofiya* (*Sofia*): Govt., 1936, pp. 48, figs. 7; *Eng. abs.* pp. 45-47).—In this discussion of the pyrethrum-growing industry in Bulgaria, the author states that with respect to pyrethrin content Bulgarian pyrethrum has a very high rating. Some evidence was secured that pyrethrin-producing capacity is a heritable factor, although influenced by climatic and other unknown conditions prevailing during any given growing season. The commercial culture of pyrethrum is considered practicable only when the pyrethrin content is at least 1 percent.

The wild garden, M. McKENNY (*Garden City, N. Y.: Doubleday, Doran & Co.*, 1936, pp. 123. [pl. 1, figs. 10]).—General information is presented on plant materials and culture.

FORESTRY

Forests of South Dakota: Their economic importance and possibilities, E. R. WARE (*U. S. Dept. Agr., Forest Serv., 1936, pp. 28, figs. 6*).—A survey of the State showed approximately 3.5 percent of the total area to be occupied by forests and that conifers were of first importance from the standpoint of area and of volume and quality of the timber. In a survey of plantations it was observed that two peaks of planting had occurred, one about 1885 and the other about 1900. Among factors favoring planted trees were high annual rainfall, moderate depth of the water table, and a lack of grazing. Data are presented on the annual cut in South Dakota forests, and a program for the management of the forests is suggested.

Reduction in the number of trees in maturing pine forest, L. M. TURNER (*Ill. State Acad. Sci. Trans., 29 (1936), No. 2, pp. 77, 78*).—Records taken by the Arkansas Experiment Station of trees in 23 stands of shortleaf pine, varying in age but all located on Hanceville sandy loam with a slope of approximately 20 percent and an estimated site index of 50, showed that the greatest mortality occurs in the early years of the stand. In the 7 yr. between the ninth and the sixteenth year of growth, there was a loss of 54 percent of the trees. From there on the annual losses steadily decreased; however, the number of trees in the 152-year-old forest was estimated as only 0.42 percent of the number in the 9-year-old stand.

Construction of yield tables for nonnormal loblolly pine stands, A. L. MACKINNEY, F. X. SCHUMACHER, and L. E. CHAIKEN (*Jour. Agr. Res. [U. S.], 54 (1937), No. 7, pp. 531-545, figs. 7*).—Using as a background data taken on 150 mechanically selected temporary plats established during the course of a study of the loblolly pine pulpwood resources of the Coastal Plain and eastern Piedmont sections of Virginia, North Carolina, and South Carolina, a method is suggested for preparing a yield table for even-aged, second-growth loblolly pine either pure or mixed with other species. The method involves the fitting of a growth curve to mechanically selected data, and its advantages are indicated as follows: (1) A reduction in the amount of data required to construct similar tables by the graphic method, (2) a minimization of errors due to personal bias in freehand curve fitting, and (3) the computations provide statistical measures of the fit of the curve as well as measures of the errors to be expected when the estimating mechanism is applied to other data. Disadvantages are listed as follows: (1) There is involved a rather laborious procedure as well as a knowledge of correlation analysis, (2) the approximation method of determining maximum yields is not based on unimpeachable assumptions, and (3) predictions of growth and future yields are adequate only when information on the changes in density and perhaps in site and composition are also available.

Yield, stand, and volume tables for even-aged upland oak forests, G. L. SCHNUR (*U. S. Dept. Agr., Tech. Bul. 560 (1937), pp. 88, figs. 22*).—Stating that the upland oak region comprises approximately one-fifth of the commercial forest area of the United States and that the destruction of the chestnut has altered the growth capacity of certain stands and hence the usefulness of some of the earlier tables, the author presents tables based on measurements obtained on sample plats and on trees cut in logging operations throughout the region. Although 15 species of oak and 50 of associated trees occurred in innumerable combinations, 5 oaks—white, black, scarlet, chestnut, and red—made up 83 percent of the stand basal area. The maximum mean annual growth of the merchantable stems on an average site was found to be 47 cu. ft., or about 0.55 cord per acre. Culmination of growth for the merchantable stand occurred at

about 55 yr. on the best site and at 90 yr. on the poorest. The growth rate was within 5 percent of the maximum for approximately 50 yr. on the average site, the best site arriving at this point at about 45 yr. and the poorest at about 70 yr. White oaks were found to decrease and black oaks increase in number with increasing site quality.

Yield of even-aged stands of Sitka spruce and western hemlock, W. H. MEYER (*U. S. Dept. Agr., Tech. Bul. 544* (1937), pp. 86, pls. 5, figs. 21).—Asserting that in general the hemlock-spruce type is associated with a climate characterized by high precipitation, frequent fogs, moderate temperature, and the absence of extreme winter cold, the author discusses the silvical characteristics of the Sitka spruce and western hemlock and presents data in the form of yield, stand, and volume tables, and information on growth and yield for different aged groups on various quality sites. The better the quality of the site, the faster the diameter, height, and volume growth of single trees and of entire stands. Sitka spruce was found usually to produce larger and taller trees than western hemlock, and as a result stands having greater percentages of spruce had greater basal areas, greater average diameters, and greater cubic-foot and Scribner board-foot volumes. On comparable quality sites, the spruce-hemlock type considerably outyields the Douglas fir type.

Ohio Forests News, [May 1937] (*Ohio Forest News [Ohio Sta.], No. 31* (1937), pp. 8, fig. 1).—In the usual manner (E. S. R., 77, p. 50), there are presented items of general information regarding forest planting and forest management and notes concerning the activities of the Federal forest agencies, such as the Central States Forest Experiment Station.

Fire Control Notes, April 12, 1937 (*U. S. Dept. Agr., Forest Serv., Fire Control Notes, [No. 4],* (1937), pp. 168–227, figs. 18).—General information is included on the use of airplanes as conveyors of supplies, on radiophone equipment, held line production, power-driven saws, emergency landing flares, etc.

DISEASES OF PLANTS

Crop losses from plant diseases in the United States in 1936, compiled by H. A. Eason and J. I. Wood (*U. S. Dept. Agr., Bur. Plant Indus., Plant Disease Rptr., 1937, Sup. 100, pp. 47–49*).—“These estimates have been computed and are presented in the same manner as in previous years” (E. S. R., 76, p. 339), including data for the same crops. Some of the outstanding variations between the 1935 and 1936 estimates are listed.

The Plant Disease Reporter, June 1 and 15, 1937 (*U. S. Dept. Agr., Bur. Plant Indus., Plant Disease Rptr., 21* (1937), Nos. 10, pp. 179–189, figs. 2; 11, pp. 191–219, fig. 1).—The following items of current interest are included:

No. 10.—Unreported powdery mildews (31 California hosts of species of *Erysiphe* and *Podosphaera* apparently not previously recorded for the United States), by C. E. Yarwood; downy mildew and bacterial leaf spots of tobacco in Kentucky (current season reports), by E. M. Johnson; downy mildew development on tobacco in North Carolina and Virginia, April 20 to May 15, by P. R. Miller; fruit disease situation in Illinois, by K. J. Kadow; fruit diseases in Missouri, by M. A. Smith; plant diseases in Kentucky in 1937, by W. D. Valleau; plant diseases reported from Arkansas, by V. H. Young; and notes on diseases of ornamentals in Oregon, by F. P. McWhorter.

No. 11.—Present conditions favor outbreak of stem rust in the Plains region, by H. B. Humphrey et al.; rusts on cereals in Virginia (to June 5), by G. E. Matheny; loose smut (*Ustilago tritici*) of wheat serious in Kansas, Oklahoma, and Texas, by C. O. Johnston; unusual amount of wheat bunt (*Tilletia* spp.) in

Texas, by I. M. Atkins; crown rust and smut-resistant oat varieties, by H. C. Murphy; reaction of certain varieties of wheat to infections of powdery mildew at Manhattan, Kans., 1932-35 (contribution by the Kansas Experiment Station in cooperation with the Bureau of Plant Industry, including data for varieties of hard red winter, soft red winter, white winter, hard red spring, soft red spring, white spring, durum, and Poulard wheats. and for *Triticum dicoccum*, *T. monococcum*, and miscellaneous *Triticum* species), by C. O. Johnston, H. Fellows, and L. E. Melchers; bacterial wilt of sweet corn on Long Island, by M. C. Richards; preliminary report of cotton diseases in Virginia, by P. R. Miller and J. Godkin; fruit diseases reported from New York, by various observers; fruit disease situation in Illinois, by K. J. Kadow; fruit diseases reported from Idaho, by E. Blodgett; vegetable diseases in Nassau County, Long Island, by M. C. Richards; downy mildew (*Peronospora destructor*) of onion in New York, by A. G. Newhall; some unusual diseases of ornamentals in Virginia, including *Oladosporium* leaf and stem disease of snapdragons, a *Phoma* leaf spot and stem canker of *Antirrhinum* spp., and infection of *Buaya sempervirens* by *Verticillium* spp., by J. G. Harrar; diseases of Virginia ornamental trees, by J. G. Harrar and S. A. Wingard; and tobacco downy mildew (*Peronospora tabacina*) in Connecticut, by P. J. Anderson.

[Plant disease work by the New Jersey Stations] (*New Jersey Stat. Rpt. 1936*, pp. 36, 37, 69, 70-78).—Progress reports are included on cranberry false blossom control; potato work (including spray tests and fertilizer-mercury trials for control of *Rhizoctonia* and scab); diseases of vegetables (including sweetpotato diseases, cabbage clubroot, sweet corn wilt and smut, tomato diseases, cantaloup spray for bacterial wilt, rhubarb root treatment, celery blight, eggplant fruit rot and wilt, cucumber nematodes, and pea root rot); spray injury and control of apple scab; control of blackberry double blossom; and diseases of ornamentals (including rhododendron wilt, sulfur residue investigations, gladiolus scab control, red pine root rot investigations, chestnut oak blight, nematode control on gardenia, maple wilt control, *Typhula graminis* on turf, delphinium crown rot, *Septoria* sp. on chrysanthemums, and blueberry disease control).

[Plant disease work by the Wisconsin Station] (*Wisconsin Sta. Bul. 438* (1937), pp. 88, 103-120, figs. 8).—Reports of progress are included on the amount of sulfuric acid needed for control of damping-off fungi by S. A. Wilde and H. M. Galloway; the influence of weather conditions on tobacco mosaic infection, by J. Johnson and I. Hoggan (cooperative with the U. S. Department of Agriculture); tobacco "blackfire" disease, by Johnson and A. C. Braun (cooperative, U. S. D. A.); efforts to find a practical way of controlling potato scab, by J. C. Walker, R. H. Larson, and A. R. Albert; scabbed barley unsatisfactory for hogs even after the fungus is dead (including its use for malting and control of barley diseases), by R. G. Shands (cooperative, U. S. D. A.); lateness and height of corn correlate with resistance to wilt (*Phytophthora stewartii* strains studied), by S. S. Ivanoff, A. J. Riker, and J. G. Dickson; tomato diseases causing severe damage, by Walker, O. C. Whipple, and V. Wright; war waged against cabbage diseases (yellow, mosaic, and clubroot), by Walker (cooperative, U. S. D. A. and the Wisconsin Alumni Research Foundation); three new diseases of peas and beans appearing in Wisconsin (spotted wilt, virus 729, and virus 408), by Walker, Whipple, and W. Virgin; breeding of smut-resistant onions, by Walker (cooperative, U. S. D. A.); copper sprays showing promise for controlling fire blight of apple, by G. W. Keitt and J. B. Carpenter; lime-sulfur compared with substitutes for control of apple

scab, by Keitt, C. N. Clayton, and Carpenter; the problem as to whether there are other copper fungicides better than bordeaux mixture for combating cherry leaf spot, by Keitt and Clayton; and continued studies on crown gall, by J. M. Van Lanen, Riker, I. L. Baldwin, S. B. Locke, B. M. Duggar, H. A. Conner, R. Nagy, and W. H. Peterson.

The nitrogen metabolism of the crown gall and hairy root bacteria, H. A. CONNER, W. H. PETERSON, and A. J. RIKER (*Jour. Agr. Res. [U. S.]*, 54 (1937), No. 8, pp. 621-628).—From this study by the Wisconsin Experiment Station, quantitative data were obtained regarding the nitrogen metabolism of the crown gall (*Phytoplasma tumefaciens* [= *Bacterium tumefaciens*]), attenuated crown gall, and hairy root (*P. rhizogenes* [= *B. rhizogenes*]) organisms in different media. In media containing glucose and yeast infusion, about one-fourth to one-third of the total nitrogen was converted into cellular proteins. With the two crown gall forms the amino nitrogen decreased, but with the hairy root organism it did not, indicating that its formation equaled its utilization. With all three organisms, ammonia nitrogen decreased slightly and in media containing ammonium salts utilization of the ammonia occurred. In similar media minus glucose, large amounts of ammonia were formed. Protein nitrogen increased to about the same degree as with glucose present. In the presence of glucose the two crown gall forms utilized ammonium nitrate as the sole nitrogen source, but ammonia nitrogen proved more available than nitrate nitrogen. The polypeptide and amino nitrogen peptone was readily utilized by the organisms under test, resulting in increases of cellular proteins and ammonia. The fraction precipitated by tungstic acid proved less readily available.

Variation in mass isolates and monoconidium progenies of *Ceratostomella ulmi*, J. M. WALTER (*Jour. Agr. Res. [U. S.]*, 54 (1937), No. 7, pp. 509-523, figs. 6).—The observations and experiments presented indicate that *C. ulmi* comprises a wide range of cultural races. Strikingly different races appeared as sectors in isolates from diseased trees and in monoconidium progenies from such isolates. The significance of these findings to those concerned with the cultural diagnosis of the Dutch elm disease is stressed.

Trichomes of incidental importance as centers for local virus infections, L. W. BOYLE and H. H. MCKINNEY (*Science*, 85 (1937), No. 2210, pp. 458, 459).—The reported studies indicate that although the trichomes do serve as centers for local virus infection, their importance in comparison with other cells of the epidermis seems to have been overestimated.

Hydrogen sulphide injury to plants, S. E. A. MCCALLAN, A. HARTZELL, and F. WILCOXON (*Contrib. Boyce Thompson Inst.*, 8 (1936), No. 3, pp. 189-197, figs. 3).—Green plants of 29 species were fumigated in glass chambers out-of-doors during the growing season, the compressed H₂S gas being introduced in an air stream blown through the chambers. Young, rapidly elongating tissues were characteristically more sensitive to injury than older tissues. Typical symptoms were scorching of the young leaves and shoots and basal and marginal scorching of the next older leaves, mature leaves being unaffected. Symptoms were usually fully developed within a few days. Carnation, purslane, Boston fern, apple, cherry, peach, strawberry, and coleus showed no appreciable injury below 400 p. p. m.; pepper, rose, nasturtium, castor-bean, gladiolus, sunflower, buckwheat, and cornflower slight to moderate injury at 40-400 p. p. m.; and soybean, Turkish tobacco, aster, kidney bean, cucumber, tobacco (*Nicotiana glauca*), salvia, poppy, tomato, clover, radish, calliopsis, and cosmos slight injury below 40 p. p. m. and severe injury and death above 400 p. p. m. Temperature proved to be as important as H₂S concentration,

injury increasing rapidly with rises therein. In some cases wilted plants appeared less sensitive to injury than normal turgid plants. Aster, buckwheat, sunflower, and tomato, tested for lime-sulfur injury, showed symptoms identical with those induced by H_2S .

The action of fungous spores on bordeaux mixture, S. E. A. McCallan and F. Wilcoxon (*Contrib. Boyce Thompson Inst.*, 8 (1936), No. 2, pp. 151-165, figs. 6).—In the mother liquor above freshly prepared 4-4-50 bordeaux mixture about 1 p. p. m. of soluble copper was found, but that going into solution in distilled water in contact with the dried fungicide did not exceed 0.3 p. p. m., which was insufficient to affect materially the germination of most fungus spores. Spores obtained by a vacuum technic, preventing their contamination by the medium, were suspended in water, allowed to stand for several hours, and filtered, the filtrates being placed over dried bordeaux mixture and agitated overnight. Water extracts from 100 million spores brought copper into solution as follows: *Uromyces caryophyllinus* 1.01 mg, *Sclerotinia fructicola* 0.76, *Neurospora sitophila* 0.12, *Botrytis paeoniae* 0.1, *Glomerella cingulata* 0.046, *Aspergillus niger* 0.023, and *Alternaria solani* 0.013 mg. The total solids excreted by the spores indicated that the species excreting the largest amount of solids were also most active in bringing copper into solution from the fungicide.

Comparative toxicity tests of soluble ($CuSO_4$) and insoluble (bordeaux mixture) copper indicated (with the five fungi used) little difference in sensitivity to $CuSO_4$ but considerable difference as to bordeaux mixture. Also, the spores most sensitive to the toxic effect of bordeaux mixture were, in general, the ones most active in bringing copper into solution from the fungicide. The active material in the spore excretions was in true solution, as shown by ultrafiltration tests. Practically all the active material could be removed in the first spore washing, and it was not appreciably renewed except for *N. sitophila*. By collecting 360 billion spores of the latter a quantity of spore excretion was obtained, from the lead precipitation of which 3.1 percent of malic acid was identified as present in the solid matter excreted by the spores. Amino nitrogen determinations of the excreted solids indicated the presence also of amino acids. Spore excretions were practically neutral, and hence could not act because of acidic properties. It is well known that certain amino acids form soluble complexes with copper oxide, and it has also been found that glycine, aspartic acid, and neutral sodium malate can dissolve large amounts of copper from bordeaux mixture. Comparative toxicity tests of sodium cuprimalate and of a copper glycine derivative indicated that these forms of copper exert substantially the same action as $CuSO_4$. It is believed that the salts of hydroxy acids such as malate and perhaps others, as well as of amino acids present in the spore excretions, act on bordeaux mixture to form soluble toxic copper and copper amino salts.

Stability of formaldehyde dust prepared with different absorbents, J. D. Wilson and H. C. Young (*Ohio Sta. Bimo. Bul.* 185 (1937), pp. 53-56).—Ordinary concentrated formaldehyde solution was added to a wide variety of absorbents. The mixtures were stored in tight glass jars in a cool, dark room and analyzed for formaldehyde by the official A. O. A. C. method immediately and at the end of 3 and 7 mo. Decreases of from 20 to over 80 percent in the original formaldehyde content occurred with marl, muck, gypsum, and charcoal. Corresponding decreases with kaolin, infusorial earth, sawdust, and grain hulls varied between 2.5 and 8.4 percent. In another test the latter absorbents held the strength well for 13 mo. Charcoal, muck, marl, or gypsum are not recommended except for immediate use.

Seed treatment experiments with oats naturally and artificially inoculated with smuts. R. W. LEUKEL (*U. S. Dept. Agr., Tech. Bul. 568 (1937), pp. 16*).—"In experiments with 11 varieties of oats over a 5-yr. period, higher percentages of smut usually resulted from seed inoculated by a spore suspension under vacuum than from seed inoculated similarly without vacuum or with dry spores, or from naturally inoculated seed. The smut infection caused by the evacuation method of inoculation was at times less amenable to control by disinfectants than was that caused in other ways. Oat smuts developed most abundantly in soil with a low to medium moisture content and at a temperature of about 20° C.

"The treatments that controlled oat smuts most satisfactorily were those with New Improved Ceresan, formaldehyde dip or spray, certain formaldehyde dusts, and Formacide, a paraformaldehyde dust containing a catalytic agent, which, in the presence of moisture, causes paraformaldehyde to revert to gaseous formaldehyde. The dusts were more effective if applied two or more days before sowing. All of them injured germination at times when the treated oats were stored too long without proper aeration or when the seed had a relatively high moisture content. Prolonged storage of oats treated with the above dust fungicides is not recommended unless the grain has a moisture content of about 14 percent or less, is thoroughly aerated a few days after treatment, and the storage place is cool and dry."

Rice disease investigations. T. C. RYKER (*Louisiana Sta., Rice Sta. Bten. Rpt. 1935-36, pp. 13, 14*).—"Following a summary of rice diseases in 1936, brief reports are given of studies of root rot due to *Pythium* sp.; whitetip (probably of physiological origin), cooperative with M. B. Sturgis; and *Rhizoctonia* sheath spot.

Influence of soil temperature and soil moisture on infection of stem smut of rye. L. LING and M. B. MOORE (*Phytopathology, 27 (1937), No. 5, pp. 633-636*).—"Repeated experiments were carried out (1932 and 1934) by the Minnesota Experiment Station, using constant temperature tanks in the greenhouse, to determine the effects of soil temperature and moisture on infection of rye by *Urocystis occulta*. Infection occurred commonly at soil temperatures of 5°-25° C., with decidedly less toward the extremes. The optimum temperature range for infection was 13°-17°, and possibly the lower optima were correlated with shallow planting, the lower temperature prolonging the susceptible stage of the seedlings. High soil moisture (65 percent of the water-holding capacity) reduced the amount of infection and also may have narrowed its temperature range.

Physiologic forms of loose smut of wheat. W. F. HANNA (*Canad. Jour. Res., 15 (1937), No. 4, Sect. C, pp. 141-153*).—"Four physiologic forms of loose smut of wheat have been found in Manitoba. Two of these forms were collected in the field, one on Reward and the other on Mindum. The two other forms appeared in the course of artificial inoculations in the greenhouse. The origin of physiologic forms of loose smut of wheat is discussed. It is considered that one of the forms that appeared in the course of the greenhouse inoculations may have resulted from a mutation. Evidence is put forward which indicates that different physiologic forms occur in eastern and western Canada. None of the 13 varieties of wheat used in the inoculation experiments proved to be resistant to all physiologic forms. The inoculation of Reward, Marquis, Garnet, and Pentad × Marquis with their own spores for four generations did not result in appreciably increasing the infections on these varieties. It was also shown that the healthy Reward plants that are sometimes present in a population grown from artificially inoculated seed are not resistant to loose smut, but have escaped infection because of faulty inoculation."

The role of certain fungi in the "sick wheat" problem, R. C. THOMAS (*Ohio Sta. Bmo. Bul.* 185 (1937), pp. 43-45).—This study showed a great difference in the toxic effect of the byproducts of growth of various fungi, including molds, upon the viability of wheat. All of the organisms tested are commonly associated with grains both in the field and in storage, but are important only when the moisture content of the grain is high and the temperature favorable for mold growth. *Aspergillus flavus* and *A. niger* were found to elaborate toxic products when grown upon bran, as demonstrated by the reduction of viability of normal wheat soaked in the filtrates. What further changes these molds may cause in bringing about the condition known as sick wheat, rendering the grain inferior and milled products below standard, remains to be determined.

Relation of sulphur dioxide in the atmosphere to photosynthesis and respiration of alfalfa, M. D. THOMAS and G. R. HILL (*Plant Physiol.*, 12 (1937), No. 2, pp. 309-383, figs. 12).—Extensive foliar destruction of alfalfa by SO_2 fumigation was followed by rather rapid growth of new leaves and corresponding reestablishment of photosynthetic activity. Short fumigations with high concentrations of CO_2 discontinued before producing appreciable leaf destruction, caused large reductions in the photosynthetic rate during fumigation, but photosynthesis began to increase within 1 hr. after treatment. The effect was noted in a somewhat lowered assimilatory rate for about 2 days thereafter, whereupon the rate became normal or greater than normal. A number of short fumigations at concentrations of 0.7-1.26 p. p. m. each caused definite decreases in the photosynthetic level, but immediately thereafter the activity rose to normal or greater than normal, so that the net effect of the fumigations was practically zero. Other similar tests with successive applications of low concentrations gave comparable results, or at most a very slight net reduction in total assimilation. Three long continuous fumigations (1935) showed no effect of fumigation or even a slight stimulation of apparent assimilation, with 0.24 p. p. m. for about 3 days, with 0.19 p. p. m. for 11 days, and with 0.14 p. p. m. for at least 39 days. Continued application of the higher concentrations caused a gradual reduction in the photosynthetic level, with attendant visible leaf markings and premature shedding of the older leaves. There was a definite tendency for the longer fumigations to reduce the chlorophyll content slightly, but this appeared to be without practical significance. Sulfur analyses of the leaves and stems accounted for about 90 percent of the SO_2 added in the short fumigations.

Absorption by the soil was too slight for analytical determination, but a passage outward from the roots to the soil was suggested. The rate of absorption of the gas by the leaves decreased along with the decreasing effects on photosynthesis. Leaf analyses showed large increments of sulfur in the prolonged fumigations, and when the content approached 2 percent the leaf became chlorotic and soon ceased to function. At about 1.5-1.7 percent or less the leaf appeared normal.

"The complete return to its normal level of photosynthesis, following fumigations which did not produce visible injury, would indicate that in such fumigations there is no 'invisible injury', either to the protoplasm or other plant structure."

Development of the root-knot nematode on beans as affected by soil temperature, G. R. TOWNSEND (*Florida Sta. Bul.* 309 (1937), pp. 15, fig. 1).—As a result of this study of the activity of *Heterodera marioni* on snap beans under field conditions, it was found that its developmental rate is a function of temperature. Development below 14.75° C. (58.6° F.) would not be expected,

although some may occur as low as 12°. The number of yearly generations increases with rises in temperature, so 10-12 generations per year are possible in southern Florida. About 10,000 hour-centigrade units above 12° are required for the development of each generation.

Cracked stem of celery caused by a boron deficiency in the soil, E. R. PUEVIS and R. W. RUPRECHT (*Florida Sta. Bul.* 307 (1937), pp. 16, figs. 3).—The trouble described and shown to be a symptom of boron deficiency was prevented by commercial borax applied to the soil around the plants at the rate of 10 lb. per acre about 2 weeks after they were set in the field. Probably the best way to apply such relatively small amounts is in solution, and good results were obtained with spray machines. By this method cracked stem was not only prevented, but a decided increase in yield was obtained. Borax probably must be applied every year to light sandy soils and every second or third year to peats and heavier mineral soils.

More than 10 lb. per acre is not recommended, due to the danger of injurious effects. "Solution culture studies have shown that 0.54 p. p. m. of boron in the nutrient solution produces normal growth of celery. Twenty times this amount does not produce plant injury, but decided toxicity appears when the concentration is increased to 16.2 p. p. m."

Control of southern celery mosaic in Florida by removing weeds that serve as sources of mosaic infection, F. L. WELLMAN (*U. S. Dept. Agr., Tech. Bul.* 548 (1937), pp. 16, figs. 4).—The weeds most commonly attacked by this virus include cranesbill, two species of *Physalis*, southern pokeweed, ragweed, and wild wandering-jew. The most commonly attacked flowers are periwinkle, snapdragon, zinnia, larkspur, and petunia. The vegetable crops most subject to the disease are beets, carrots, sweet corn, cucumbers, eggplants, parsley, peppers, squash, sweetpotatoes, tomatoes, and celery. The virus was found to persist in the weeds around celery fields (pokeweed and wandering-jew being most important), while it did not remain from season to season in seeds or soil. Spontaneous transmission from plant to plant and host to host is by means of aphids.

Celery mosaic was controlled in the Sanford district by removal of weeds from around the fields, while fields in the vicinity continued to be severely diseased where no attempts were made to destroy the weed hosts. Mere aphid-killing methods (spraying) proved impractical, lacking sufficient thoroughness and area covered. None of the commercial varieties common in Florida, or any foreign varieties resembling them in type, were found to be resistant. Recommendations for control include the eradication of weeds for a distance of 75 ft. or more around seedbeds and fields before planting or transplanting, the procedure to be repeated about five times during the celery-growing season.

A leaf spot disease of red and white clovers, O. F. SMITH (*Jour. Agr. Res.* [U. S.], 54 (1937), No. 8, pp. 591-599, figs. 4).—The fungus described (but not named) in this joint contribution by the U. S. D. A. Bureau of Plant Industry and the Wisconsin Experiment Station was found attacking leaves of *Trifolium pratense* and *T. repens* and was proved pathogenic also on leaves of *T. hybridum*, *T. incarnatum*, *T. repens giganteum*, *Melilotus alba*, *M. officinalis*, *M. indica*, and *Medicago sativa*. Lesions are limited to leaf-blade tissues, and under field conditions they consist of dark-brown, often irregular, necrotic areas. Concentric zones are formed around each point of infection, resembling the lesions produced on red clover by *Macrosporium sarciniforme*. With high humidity, aerial mycelium grows above the surface of infected leaves and at each contact point of a hyphal tip with the leaf it develops a group of short diverging hyphae, which serve as organs of attachment to the surface. Direct

penetration of the epidermis occurs at several points beneath these organs of attachment, and the mycelium develops both inter- and intracellularly, killing the host tissues in advance. For growth of the fungus on potato-dextrose agar and for infection of red clover, temperatures of 24° and 28° C. proved more favorable than those above or below. Since no spores or sclerotia were produced, the taxonomic position of the fungus remains undetermined.

Effect of potash fertilizers on cotton wilt, L. E. MILES (Mississippi Sta. Tech. Bul. 23 (1936), pp. 21, figs. 3).—Fairly high potash applications combined with nitrogen- and phosphorus-containing salts were definitely beneficial in the control of cotton wilt on the soils of the southern and north-central parts of the State and of the border area of the Yazoo-Mississippi Delta. High nitrate applications and fertilizers containing nitrogen and phosphorus alone were inefficient for wilt control. Potash alone reduced wilt but did not return satisfactory yields. On severely infested soils a cotton variety at least relatively resistant to wilt is essential in addition to a high-potash fertilizer. There was apparently no significant difference in the efficiency of the various sources of potash relative to wilt control.

It is pointed out that in certain parts of the State, particularly in the Delta area, the problem is complicated by the presence of two distinct wilt diseases. Even should it be determined that the disease in question is the *Fusarium* wilt, it is likely that on typical Delta soils naturally high in potash the use of this element may fail to give beneficial results.

Prevalence and significance of fungous associates of pea seeds, W. F. CROSIER (Assoc. Off. Seed Anal. North Amer. Proc., 28 (1936), pp. 101-107).—Careful examinations of 6,500 samples by the New York State Experiment Station have indicated that emphasis should be placed on a few organisms and the others regarded as probable, but not common, associates of the seed. *Ascochyta pisi*, *A. pinodella*, and *Mycosphaerella pinodes* occur annually in several samples, and various pathogenic species of *Fusarium* are associated with pea seeds. Statistical analyses are presented on the relation of certain seed associates to the emergence, growth, and stand of peas, including the genera *Fusarium*, *Rhizoctonia*, *Ascochyta*, *Sclerotium*, and *Botrytis*. The association of other pathogenic fungi with commercial seedstocks proved too infrequent to permit statistical treatment, but a partial list is given.

Two mosaic diseases of peas in Washington, F. JOHNSON and L. K. JONES (Jour. Agr. Res. [U. S.], 54 (1937), No. 8, pp. 629-638, figs. 5).—Two virus diseases, designated as enation mosaic and severe mosaic, are said to be destructive to pea plantings in Washington, the greatest damage occurring in market-garden and canning peas in the western part of the State.

Seed transmission tests by the Washington Experiment Station indicated the two viruses to be rarely carried in the seed. Severe mosaic has a wide host range among legumes, while enation mosaic is much more limited in its hosts. The two viruses differ in the symptoms induced, in tolerance to dilution, in viability in vitro and in dried plant tissues, in inactivation by heat, and in percentage of infection following mechanical inoculation.

Inheritance of resistance to tobacco-mosaic disease in the pepper, F. O. HOLMES (Phytopathology, 27 (1937), No. 5, pp. 637-642).—All tested varieties of the garden pepper (*Capsicum frutescens*) proved susceptible to infection with tobacco-mosaic virus (tobacco virus 1, distorting strain). Four types of response to infection were found. Two of these were known previously, viz, systemic chlorosis and localized necrosis followed by abscission and recovery. A third, here described, is a delayed necrosis, with abscission of affected leaves often allowing the plants to escape systemic spread of the virus. The fourth is a systemic necrosis, with stem streak and eventual death in all plants.

These four responses are controlled by three genes, which form an allelic series. The gene *L* (localization of tobacco-mosaic virus) is completely dominant over *l*¹ (imperfect localization of virus) and *l* (mottling). The gene *l*¹ is partially dominant over *l*. Infected plants of genetic constitution *ll* show systemic chlorosis, *ll*¹ delayed necrosis with leaf abscission and recovery in many plants and small numbers of secondary lesions in a few, *ll*¹ systemic necrosis in all plants, and *LL*, *Ll*, and *Ll*¹ localized necrosis with subsequent recovery.

Resistance of the potato to latent mosaic, E. S. SCHULTZ, C. F. CLARK, F. J. STEVENSON, and W. P. RALEIGH (*Amer. Potato Jour.*, 14 (1937), No. 4, pp. 124-127).—"This paper presents information on the reaction to latent mosaic of potato seedling varieties from two crosses, S 41956 × Katahdin and S 41956 × S. 45075." Although the data obtained are not deemed sufficient to permit a complete genetic analysis of the various reactions, the results are believed to indicate that immunity to latent mosaic of the parent S 41956 was transmitted to a high percentage of the progeny of the two crosses.

Report on potato virus diseases in 1936, T. P. DYKSTRA (*Amer. Potato Jour.*, 14 (1937), No. 4, pp. 117-124).—This is a review for 1936, including "the papers dealing with timely and general interest . . . and the principal conclusions derived from them", with a bibliography of 30 references.

Correlation between movement of the curly top virus and translocation of food in tobacco and sugar beet, C. W. BENNETT (*Jour. Agr. Res. [U. S.]*, 54 (1937), No. 7, pp. 479-502, figs. 6).—The time required for invasion by the curly top virus varies somewhat with the size of the plant, seedlings probably being almost completely invaded in 2-4 days. In some larger plants over 4 weeks were required for the virus to pass from a mature inoculated leaf to one noninoculated on the opposite side of the plant. In Turkish tobacco (*Nicotiana tabacum*) the virus moved downward more rapidly than upward. In two tests with *N. glauca* the virus moved downward 3 ft. from infected Turkish tobacco grafts at the top and induced symptoms on healthy grafts at the base in averages of 28 and 32 days, respectively. When the positions of the diseased and healthy Turkish tobacco grafts were reversed, the virus required 180 and 302 days, respectively, to move upward and cause symptoms on the top grafts. In some cases it did not reach the tops in an average time of over a year, but when such plants were defoliated at the top the virus moved into the top grafts and induced symptoms in an average of 18 days after defoliation. Other tests indicated that the virus moved only a short distance from the bottom infected graft in 3 mo. in *N. glauca* plants with abundant foliage on the tops, but after top defoliation the virus invaded the upper part of the plants in 14 days or less. When one of the three shoots of a beet plant was infected with curly top and a second shoot was defoliated or held in darkness for 5 days after inoculation, the virus passed into the defoliated or darkened shoot and induced symptoms in an average of 10.6-17.6 days, which was 0.1-5.6 days longer than the average for production of symptoms on the inoculated shoot. The third shoot remained free from symptoms for averages of 55-183 days.

Tests with leafhoppers indicated that the virus moved from inoculated shoots showing symptoms into noninoculated shoots that were both darkened and defoliated in 24-48 hr. When the virus was introduced into the distal end of etiolated beet leaves in darkness it failed to move out of the inoculated leaf in most cases within 21 days, although it moved out of green leaves in light within 4 hr. After etiolated leaves had retained the virus 5 days, it moved out of the inoculated leaf within 24-72 hr. after return of the plants to the light.

The way in which this virus invades the plants indicates that its movement bears little or no relation to its multiplication or to virus concentration gra-

dients, but that it depends on physiological processes occurring in the normal plants. It is apparent that in both beet and tobacco the virus can be prevented from entering certain parts by providing conditions for the synthesis of excess carbohydrates, and that its passage into certain parts can be induced by a food deficit. The data strongly indicate that the virus movement is correlated with food transport and suggest that the virus may be used as an indicator of food translocation. If the virus is such an indicator, its behavior in the plant strongly supports the theory of mass movement of materials in the phloem.

Virus studies.—III, Tomato diseases, W. NEWTON and H. I. EDWARDS (*Canad. Jour. Res.*, 15 (1937), No. 4, Sect. C, pp. 162-167).—Continuing this series of studies (E. S. R., 77, p. 56), "single virus streak, potato virus X, streak virus X, and aucuba mosaic (tobacco virus 6) were found causing diseases of tomatoes in commercial glasshouses in British Columbia during 1936. Single virus streak was the commonest disease, although greater losses were caused by streak virus X. Aucuba mosaic was found in one case only, but was highly pathogenic. Potato virus X was present mixed with single virus streak, giving rare cases of mixed virus streak. Tomato mosaic (tobacco virus 1) was not present as a tomato disease. Single virus streak serum did not give a precipitate when mixed with aucuba antigen, thus indicating that the viruses are distinct. However, a slight precipitate with tobacco virus 1 antigen did indicate distant relationship with this form. Although three strains of single virus streak could be distinguished by symptoms produced on tomatoes when inoculated simultaneously, these strains proved to be serologically identical."

Pathogenic associates of tomato seed: Their prevalence, relation to field disease, and elimination, J. H. MILLER and W. F. CROSIER (*Assoc. Off. Seed Anal. North Amer. Proc.*, 28 (1936), pp. 108-111).—This contribution from the University of Georgia and the New York State Experiment Station summarizes data on the subject, with special reference to the dissemination of organisms with the seeds. The evidence accumulated in 1935 indicated that commercial seeds were the chief source of all primary infections. A method was developed at Athens, Ga., to determine the presence of important pathogens on the seed and thereby to test the effectiveness of field inspections, of fermentation for bacterial canker, and of chemical seed disinfection (particularly with mercuric chloride). The organisms commonly observed were *Macrosporium solani*, *Bacterium vesicatorium* (= *Phytophthora vesicatoria*), and *Aplanobacter michiganense* (= *P. michiganensis*), while occasional cultures of *Colletotrichum pomoides*, *Phoma destructiva*, and *Fusarium lycopersici* were obtained. Evidence for the translation of the seed load into field disease was found in both 1935 and 1936.

Relation of nutrient salt concentration to growth of the tomato and to the incidence of blossom-end rot of the fruit, W. R. ROBBINS (*Plant Physiol.*, 12 (1937), No. 1, pp. 21-50, figs. 8).—In this contribution by the New Jersey Experiment Stations, tomatoes from a selected strain of the Marglobe variety were grown in sand cultures in the greenhouse with nutrient solutions of osmotic concentrations of 0.08, 0.44, 0.83, 1.7, and 3.1 atmospheres, a comparison also being made of the effects of two rates of supply of the first solution. The detailed effects of these solutions on vegetative growth, fruit set and growth, internal water relations, and dry weights of the various plant parts are noted.

About 80 percent of the fruits grown with solutions of the two highest concentrations developed the physiological disorder blossom-end rot, while with the lowest concentration none developed this condition. Blossom-end rot was associated with wide fluctuations in transpiration rates. A slight amount of cracking of fruits occurred under low transpiration intensities, but only in

plants with the lowest concentration of solution. A difference of about 4 atm. occurred between the osmotic values of extracted juices of similar tissues of plants grown with solutions of the lowest and highest concentrations. An osmotic gradient of 1.62–3.63 atm. existed between the extracted juices of fruit v. stem and leaf tissues in plants grown with the various concentrations of solution, the smallest gradient occurring in plants grown with the lowest concentration.

The significance of the differences in osmotic and imbibitional pressures of fruit, stem, and leaf in the various series and the importance of factors of light, temperature, humidity, air movement rate, and of the pH and oxygen tension of the solutions in relation to the development of blossom-end rot of the fruit in solutions of different nutrient salt concentrations are either noted or discussed. A bibliography of 37 references is provided.

Experiments for the control of *Phoma* rot of tomatoes, W. B. TISDALE and S. O. HAWKINS (*Florida Sta. Bul. 308* (1937), pp. 28).—It is stated that the *Phoma destructiva* rot has been known in tomatoes shipped from the lower east coast of Florida since 1915, and since then it has been reported to be the most important single cause of spoilage in fruits shipped from the State and second in importance as a single cause of decay in winter-grown tomatoes in transit from certain other Southern States. Experiments during 5 yr. at Homestead indicated that *Phoma* spot occurs extensively there on the foliage of the winter crop during seasons of moderate temperatures and high relative humidities, while during warm, dry seasons the disease is less prevalent and may cause little or no injury. The prevalence was determined by placing mature-green fruits from the plats in storage until they ripened.

Spraying tests indicated that 4–4–50 bordeaux mixture increased the yields of marketable fruits and prevented a high percentage of rot from developing in stored fruits during seasons favorable for its development, but during warm, dry seasons the bordeaux reduced the yields of marketable fruits. The rot was further reduced by washing the fruits immediately after picking with a 5 percent solution of borax, a 1 percent solution of sodium hypochlorite, or a 1–150 solution of sodium polysulfide, each containing 0.5 percent of liquid tar soap as a wetting agent, the borax proving slightly more satisfactory. The best place for applying the treatment was in the field. All forms of mechanical injury in handling and picking while the fruits are wet with fog or dew should be avoided. Chemically treated wraps failed to reduce the percentage of rot in stored fruits.

“Among the varieties tested, Livingston Globe, Marglobe, and Pritchard showed most resistance to both leaf and fruit infection. During the 1935–36 season the Rutgers variety showed most resistance to leaf infection, but because of the hurricane no fruits were available for comparative tests.”

The effect of various spray materials on tomato transplants, J. D. WILSON and H. A. RUNNELS (*Ohio Sta. Bimo. Bul. 185* (1937), pp. 52–65, figs. 3).—Since various spray materials, particularly bordeaux mixture, had been observed (E. S. R., 77, p. 60) to increase the transpiration rate of plants with definite injury resulting, it was decided to test the effect of these materials upon plants sprayed shortly before or after transplanting. Plants of the usual size for transplanting were sprayed previous to their removal from the seedling flat, transplanting taking place as soon as the leaves were dry and at from 1- to 7-day intervals thereafter.

In pots filled with soil of a medium moisture content bordeaux mixture was consistently found to be very injurious, even causing the death of many of the plants when transplanting took place immediately after treatment. Plants

treated with an oil emulsion (Volck 1-100) were little affected, and Volck added to bordeaux mixture greatly alleviated the injury caused by it. Practically all of the spray materials tested which were capable of increasing transpiration, such as most of the copper-containing compounds, and materials sometimes used as diluents or stickers were found to be more or less injurious in case of immediate transplanting. Some of these materials, however, particularly copper oxychloride and cuprous oxide, caused only negligible injury if a delay of 48 hr. occurred between spraying and transplanting, and even with bordeaux mixture the plants were but little affected if 5 days intervened. Observation also indicated that bordeaux mixture should not be used on newly transplanted plants until they have had the opportunity to reestablish their root systems to the extent that water absorption can keep pace with water loss.

The control of mosses and lichens on fruit and nut trees, P. W. MILLER (*Oreg. Agr. Col. Ext. Bul. 498* (1937), pp. 4).—Lime-sulfur and bordeaux mixture are stated to be two of the most effective sprays for this purpose. Directions for preparation and application, together with certain precautions, are given.

Calcium and boron contents of the apple fruit as related to the incidence of blotchy cork, W. A. DeLONG (*Plant Physiol.*, 12 (1937), No. 2, pp. 553-556).—Parallel samples of Stark apples (some visibly affected and others apparently normal), collected from a number of orchards and analyzed for calcium and boron, gave no evidence that blotchy cork results from boron deficiency, nor was there evidence that the boron and calcium contents of the apple are closely related. The previous finding that blotchy cork is associated with a relatively low calcium content of the fruit was confirmed.

Incidence of fire blight in young apple trees in relation to orchard practices, E. M. HILDEBRAND and A. J. HEINICKE ([*New York*] *Cornell Sta. Mem.* 203 (1937), pp. 36, figs. 2).—The present study involved five varieties of apple trees, 4 yr. old at the beginning and ranging in blight susceptibility from low to high as follows: Delicious, Northern Spy, McIntosh, Cortland, and Rhode Island Greening. The severity of annual injury varied and was correlated with the initial blossom infections. A total injury of 50 ft. occurred in over 50 percent of the Rhode Island Greening trees, the percentages for the other varieties being, roughly, Cortland 18, McIntosh 13, Northern Spy 3, and Delicious less than 0.5. Spur blight was most serious on Cortland. Shoot, branch, and body blight was most serious on Rhode Island Greening, with very little injury on Cortland and Northern Spy and but slight damage to McIntosh and Delicious.

Cultural treatments, as listed in the order of the blight susceptibility induced, were cultivation, alfalfa, and sod.

With pruning once in 3 yr., body blight was about nine times greater than on unpruned trees. In general, nitrogen fertilization increased the total fire blight injury, but branch blight was decreased, probably due to the reduction in spurs which function as courts of infection.

Comparing the trees with alfalfa, cultivation, and sod, alfalfa without nitrogen fertilization gave the most satisfactory results with respect to blight and growth combined. Ringing tended to increase blight susceptibility both in the current and following seasons.

It is concluded that the use of a carefully selected cultural practice in conjunction with other measures, such as blossom bactericides, offers promise for fire blight control, particularly on apple.

The peach mosaic disease, L. M. HUTCHINS (*Calif. Dept. Agr. Spec. Pub. 145* (1936), pp. 60-61).—This virus disease was successfully transmitted by grafting, but the natural mode of spread has not yet been determined. The symptoms,

incubation period, and rate of spread are briefly discussed. The disease is most serious on the Elberta varieties. It is known to occur in Texas, Colorado, California, Utah, New Mexico, and Arizona.

Incubation period of peach yellows in its insect vector, *A. HARTZELL* (*Contrib. Boyce Thompson Inst.*, 8 (1936), No. 2, pp. 113-120, fig. 1).—To determine the approximate incubation period of this virus in the vector *Macropsis trimaculata*, nymphs were allowed to feed on affected seedling peach trees in the greenhouse for periods of 1, 4, 7, and 10 days prior to being placed on healthy trees. Only those of the 4-day series proved infective. The maximum incubation period of the virus as experimentally determined ranged from 10 to 26 days (average 16 days), while the minimum period in one case was from 7 to 8 days. All positive infections were obtained with insects becoming infected as nymphs and allowed to feed on healthy trees during that stage, except for one case where the leafhoppers had transformed to adults on healthy trees during successive transfers, the maximum period in this case being 26 days.

A bibliography of 21 references is appended.

Bunch disease of pecans, J. R. COLE (*Phytopathology*, 27 (1937), No. 5, pp. 604-612, figs. 4).—This disease, which was definitely determined in the spring of 1932 as new to pecans, was first observed in the Red River Valley, near Shreveport, La. It is believed to have first attacked the wild native pecan (*Hicoria pectan*) and the water hickory (*H. aquatica*), both being indigenous to the alluvial river-bottom soils, and to have spread gradually to the susceptible improved varieties of pecans. The disease is known to occur in Louisiana, Mississippi, Oklahoma, and Texas. The brooming of branches and shoots, early foliation of diseased branches in the spring; chlorotic, thin, broad, wavy, and flexible leaves; and, in later stages, dying back of the branches are characteristic symptoms. Certain symptoms resemble rosette and little leaf of pecans, phony peach and peach yellows, and witches'-broom of black locust. Bunch disease was successfully transmitted by grafting diseased Schley scions to healthy Schley stocks. It is probably of virus origin. The Schley and Mahan varieties are very susceptible, while Stuart is highly resistant.

Oklahoma demonstrations in the control of pecan rosette, W. D. ARMSTRONG (*Okla. Pecan Growers' Assoc. Proc.*, 1936, pp. 75-77).—This is a brief review of the pecan rosette situation in the State and of progress in the steps being taken to control it, including the soil, spray, and insertion methods of applying zinc sulfate.

Boron-deficiency effects similar in general appearance to bark symptoms of psorosis in citrus, A. R. C. HAAS (*Soil Sci.*, 43 (1937), No. 4, pp. 317-325, pls. 3).—Since in this study by the California Citrus Experiment Station boron-deficiency effects imitating the bark symptoms of psorosis were induced in citrus, it is concluded that, although the two diseases apparently originate differently, their effects may be closely similar.

Bacterial leaf spot of begonia, L. McCULLOCH (*Jour. Agr. Res. [U. S.]*, 54 (1937), No. 8, pp. 583-590, fig. 1).—A bacterial leaf spot of cultivated begonias, causing defoliation in severe attacks and unsightly plants and leaves in lighter infections, is shown to be due to *Bacterium flavosolatum* n. sp. Though resembling *B. campestre*, inoculations on cabbage, rutabaga, radish, and horseradish gave negative results, but a very slight infection was sometimes induced on geranium. The disease occurs widely in the United States.

"Warm, moist, poorly ventilated, and crowded conditions favor the development of the disease. Adequate spacing, with regulated temperature and moisture, is usually effective in preventing or in curing the disease. Rapid forcing should be avoided, and spotted leaves should be removed or destroyed."

A bacterial blight of iris, W. W. BURKHOLDER (*Phytopathology*, 27 (1937), No. 5, pp. 613-621, fig. 1).—A bacterial blight of iris leaves, possibly of widespread distribution, is reported in this contribution from Cornell University. It is favored by warm, wet weather and occurs on various species of iris. The pathogen is shown to be a vascular parasite which enters the host plant through wounds. The name *Phytomonas tardicrescens* (= *Bacterium tardicrescens* McCulloch) n. comb. is applied.

Decay in merchantable oak, yellow poplar, and basswood in the Appalachian region, G. H. HEPTING and G. G. HEDGECOCK (*U. S. Dept. Agr., Tech. Bul.* 570 (1937), pp. 30, figs. 7).—This study was conducted from 1924 through 1928, sampling being done in connection with commercial logging operations on 55 plots in 19 localities from New Jersey to Tennessee and west to southeastern Ohio. Data were analyzed on 5,882 trees of white oak, chestnut oak, post oak, red oak, black oak, scarlet oak, yellow poplar, and basswood. The identity of some of the fungi responsible for decay was established through cultures, but insufficient knowledge of the cultural characters of many wood-destroying species precluded their identification by this means.

The percentage of cull for any one species varied considerably with locality, much variation being traced to differences in the amount of basal wounding. The importance of basal wounding was emphasized by the fact that 77 percent of the total cull volume resulted from butt defect, 20 percent from top rot, and 3 percent from miscellaneous causes. The cull percentage increased with the diameter and age of the tree, correlated in part with an increase in proportion of trees wounded at the base as their age and diameter increased.

The height of butt rot increased with tree age up to a certain point, beyond which there was, in some cases, either no increase or a decrease. Through measuring the rot in several hundred logs with rot at one end, while being sawed, a general curvilinear relation was found between the average diameter of rot and the length of the rot column. There was a larger percentage of butt cull in stump sprouts than in seedling sprouts in six of the eight species studied. The most common type of wound on standing timber was that due to fire. Relative to the healing of basal wounds, in oaks the callus folds converged toward each other at an average rate of 0.45 in. per year for trees on good sites, 0.34 in. for medium sites, and 0.31 in. for poor sites. For yellow poplar the rate was 0.73 in. for good and 0.33 in. for medium sites. Of trees on which no basal wounds were found, only 6 percent showed butt rot, with 15 percent culls, while of trees with basal wounds 67 percent showed butt defect, with 15.5 percent culls. The butt-cull volume increased with width of basal wound and with tree age at time of wounding.

"The increase in cull percentage with increase in tree diameter and percentage of trees with basal wounds is presented by means of three variable graphs. By determining the percentage of trees with basal wounds for each diameter class, the cull percentage for a stand of the species studied, if primarily of seedling or seedling-sprout origin, may be approximated from these graphs."

Preliminary studies of the transfer of four strains of *Ditylenchus dipsaci* (Kühn 1858) Filipjev 1936, R. J. HASTINGS and W. NEWTON (*Canad. Jour. Res.*, 15 (1937), No. 4, Sect. C, pp. 168-174).—"The bulb and stem nematode, *D. dipsaci*, attacks narcissus, iris, red clover, and strawberry in the Pacific Northwest. The isolations from each of these important crops are herein described as strains. Preliminary studies of the transfer of these strains establish the existence of three strains of *D. dipsaci* in the Pacific Northwest, viz: (1) Red clover strain, characterized by causing swollen crowns and stunt in red clover seedlings; (2) strawberry strain, characterized by a limited host

range, swollen crowns in strawberry seedlings, and entrance into red clover seedlings without visible tissue reactions; [and] (3) narcissus and iris strain, characterized by a wide host range and entrance into clover and strawberry seedlings without visible tissue reactions.

"No satisfactory technic of establishing the host range of the biological strains of *D. dipsaci* has been developed. The clamping of glass rings filled with a nematode suspension in moist pulverized peat to the foliage of test plants did not affect the test plants in a constant manner. The examination of seedlings after clarification in a lactophenol solution containing acid fuchsin gave more constant results. The seedlings were removed from infested soil shortly after they appeared above ground. The reports of host specificity of the red clover strain were not confirmed, for the red clover strain entered white clover and alfalfa, hitherto considered resistant. Likewise, the reports of host specificity of the narcissus strain were not supported by our experimental results. The narcissus strain entered red clover and oats, also considered resistant hitherto."

ECONOMIC ZOOLOGY—ENTOMOLOGY

[Work in economic zoology and entomology by the New Jersey Stations] (*New Jersey Stat. Rpt. 1936*, pp. 32, 33, 40, 41, 48-53, 103).—Work of the year (E. S. R., 75, p. 658) with oysters includes production of seed oysters, open shore and claire culture of oysters, filtration of water by oysters and the factors influencing it, and the eradication of oyster drills in Delaware Bay. Entomological work reported includes blueberry fruitworms (the cherry fruitworm and the cranberry fruitworm); the blueberry maggot; mosquito investigations and control; investigations of climate and insects, spraying for orchard and vegetable insects, action of insecticides, soil-infesting insects, bees, and ornamental plant insects; and a study of the relation of the microbiological population of the soil to the destruction of Japanese and other beetles.

[Work in economic zoology and entomology by the Wisconsin Station] (*Wisconsin Sta. Bul. 438 (1937)*, pp. 61-64, 121-123, figs. 3).—Reference is made (E. S. R., 75, p. 512) to the increase of the farm game population at Riley; the response of prairie chickens and sharp-tailed grouse to fall and winter feeding, by F. J. W. Schmidt (E. S. R., 76, p. 821); the value of early application of cutworm bait, by H. F. Wilson and C. D. Harrington; use of fly sprayers, by E. M. Searls and F. M. Snyder; attack of alfalfa by the false chinch bug and the tarnished plant bug during the drought of 1936, by Searls; control of the striped cucumber beetle by derris and reduction of effectiveness of derris for cabbageworms caused by alkaline carriers, both by T. C. Allen; effective control of pea aphids by derris, by J. E. Dudley, Jr., T. E. Bronson, and F. E. Carroll of the U. S. D. A. Bureau of Entomology and Plant Quarantine; control of the three-lined potato beetle, by C. L. Fluke; and control of insects (principally the fruit tree leaf roller, eye-spotted budmoth, and cherry casebearer) in Door County apple orchards, including the effects of dormant oil sprays on the growth of apple trees, by J. H. Lilly.

Flight speed of birds, M. T. COOKE (*U. S. Dept. Agr. Circ. 428 (1937)*, pp. 14).—In this contribution, based upon a review of the literature (86 references to which are listed) and records of the Bureau of Biological Survey, the speed of flight of birds is principally dealt with. Reference is also made to the altitude of migratory flights and the mechanics or aeronautics of flight. A brief introduction is followed by a discussion of estimated speeds, measured speeds, and variations in speed, including the effect of wings and weight and influence of wind. The details are given in a table (pp. 6-9) of the species observed,

with their speeds in miles per hour, timing device used, place, authority, and remarks.

Further notes on the food and habits of Trinidad birds, with special reference to common cane field birds, D. VELSEY-FITZGERALD (*Trop. Agr. [Trinidad]*, 13 (1936), No. 1, pp. 12-18).—Examinations of an extensive series of stomachs of some 50 species of birds collected in Trinidad in July and August 1931 are reported upon, followed by an annotated list of 17 references to the literature.

The birds of St. Kitts and Nevis, S. T. DANFORTH (*Trop. Agr. [Trinidad]*, 13 (1936), No. 8, pp. 213-217).—An annotated list of 63 forms from St. Kitts and Nevis.

Costs and profits in oyster drill control, L. A. STAUBER and G. M. LEHMUTH (*New Jersey Stat. Bul.* 624 (1937), pp. 10, figs. 3).—This contribution deals with the oyster drill or borer, a detailed account of the life and habits of which have been noted in Bulletin 523 (E. S. R., 65, p. 243). Methods for its control, with description of the drill dredge, the chicken-wire trap, and a third practical method of control by the use of large mesh-iron screens on boats, are presented. It is pointed out that of these methods the drill dredge is useful in clearing an oyster bed of drills before seed oysters are planted on it in the spring of the year; that trapping is the most important single method since it decreases the destruction caused by the drills at the most crucial stage in the life of the oyster, when the oysters are young and most easily drilled, and because it removes borer eggs; and that screens on the boat deck should be used during replanting and harvesting of oysters.

In the calculations of costs and profits here reported, 20 was used as the number of oysters that can be destroyed by one borer in a season because that is the most conservative figure in the records.

Common names of insects approved for general use by the American Association of Economic Entomologists (*Jour. Econ. Ent.*, 30 (1937), No. 3, pp. 527-560).—This is a compiled list of the common names of insects thus far approved by the association and a list of the scientific names (E. S. R., 73, p. 807).

Dissemination of insects by air currents, E. P. FELT (*Jour. Econ. Ent.*, 30 (1937), No. 3, pp. 458-461).—The results obtained in the release of 4,935 balloons between May 9 and July 23, 1936, from points in Connecticut, New York, and New Jersey in their bearing upon the spread of certain insect pests, particularly the smaller European elm bark beetle, are considered.

[Notes on economic insects and their control] (*Jour. Econ. Ent.*, 30 (1937), No. 3, pp. 560-564).—The notes here presented (E. S. R., 77, p. 850) are as follows: Oxygen as a Factor in Vacuum Fumigation, by R. T. Cotton, G. B. Wagner, and H. D. Young (p. 560); Greatly Increased Yields of Peanuts Obtained in Attempts to Control Potato Leafhopper, by F. W. Poos and E. T. Batten (p. 561); U. S. D. A. Bureau of Entomology and Plant Quarantine and the Virginia Experiment Station; Zinc Oxide-Zinc Acetate Mixture as a Safener for Arsenical Sprays, by R. H. Robinson and L. Childs (pp. 561, 562), Oregon Experiment Station; Effect of Ferric Oxide on Acid Lead Arsenate as a Stomach Poison and Repellent for Japanese Beetle, by W. E. Fleming and F. E. Baker (p. 562); *Lariophagus distinguendus* Foerst. Parasitic on *Sitotroga panicea* L. in New York, by L. L. Pechuman (p. 563); New Technic for Hatching Codling Moth Eggs, by D. Powell (pp. 563, 564), Illinois Natural History Survey and Illinois Experiment Station; and Improved Poisoned Bait for Corn Root Webworm Affecting Tobacco, by J. U. Gilmore and J. Milan (p. 564).

Records of southern insect species moving northward during the drouth years of 1930 and 1934. H. H. KNIGHT (*Ann. Ent. Soc. Amer.*, 29 (1936), No. 4, pp. 578-580).—A brief account is given of the fluctuating range of a few species taken at Ames, Iowa, which is said to be as great as from 300 to 500 miles in a north and south direction.

Further notes on the food-plants of Nigerian insects, IV. F. D. GOLDING (*Bul. Ent. Res.*, 28 (1937), No. 1, pp. 5-9).—Observations made from November 1934 to March 1936, in continuation of those previously noted (*El. S. R.*, 73, p. 808), are reported.

The need of permanent reference collections of insect vectors of plant diseases. F. F. SMITH (*Phytopathology*, 27 (1937), No. 2, pp. 198-202).—Attention is directed to the desirability of bringing together representatives of all available bona-fide and present-known insect vectors of plant viruses in one or more leading institutions conducting research on virus diseases. These should serve as repositories for such material from future investigators.

[Rice insect work by the Louisiana Rice Station] (*Louisiana Sta., Rice Sta. Bien. Rpt.* 1935-36, pp. 12, 13, 16-19).—A review of the progress of work with rice field insects is presented by W. A. Douglas and of insect control in stored rice by C. L. Stracener.

Insects attacking sugar-cane on the island of Tobago. B. W. I., D. VESEY-FITZGERALD (*Trop. Agr. [Trinidad]*, 13 (1936), No. 8, pp. 199, 200).—An account of the occurrence of insect damage on a neighboring island of Trinidad.

Notes on sugar cane in west Africa. R. H. VAN ZWALUWENBURG (*Hawaii. Planters' Rec. [Hawaii. Sugar Planters' Sta.]*, 41 (1937), No. 1, pp. 7-12, figs. 5).—Observations made of the animal enemies of sugarcane during the course of a trip of investigation from November 9, 1935, to July 23, 1936, in west Africa are reported. The village weaver or palm bird (*Ploceus cucullatus cucullatus*), which strips the leaves of sugarcane, bananas, and palms to weave into its hanging nests, was found to be the most conspicuous pest of cane in Sierra Leone. It was also observed in Liberia, Ivory Coast, Gold Coast, and Nigeria, and a similar form in Cameroun (Cameroons). A cercopid, *Locris maculata* Fab., which feeds upon corn and grasses in general is the most common and most widespread insect attacking sugarcane in Sierra Leone, being also found in the Gold Coast, Nigeria, and Cameroun. Pyralid moth borers were observed to occur all the way from Sierra Leone to Angola, and their ravages, while not comparable to the sugarcane borer in the American tropics, have to be reckoned with. The nutgrass armyworm occurs from Sierra Leone eastward, at least into Nigeria. A list is given of 16 forms of west African rutelid beetles.

Control of insects commonly affecting tobacco plant beds. H. H. JEWETT (*Kentucky Sta. Circ.* 47 (1937), pp. 9-23, figs. 7).—A practical account of control measures for insects attacking tobacco plants in the seedbed.

Biological control in the West Indies. R. G. F[ENNAH] (*Trop. Agr. [Trinidad]*, 13 (1936), No. 8, pp. 197-199).—A review of the status of the biological control of insects in the West Indies.

The introduction and colonization in Puerto Rico of beneficial insects. K. A. BARTLETT (*Puerto Rico Sta. Agr. Notes* No. 75 (1937), pp. 8).—The introductory work with beneficial insects for the control of crop pests in Puerto Rico, commenced in July 1935 and conducted in cooperation with the U. S. D. A. Bureau of Entomology and Plant Quarantine, is reported upon.

The search in the American tropics for beneficial insects for introduction into Puerto Rico. S. M. DOHANYAN (*Puerto Rico Sta. Agr. Notes* No. 76 (1937), pp. 7).—A search conducted in the British West Indies and in certain

South American countries from August 12, 1935, to May 21, 1936, is reported upon. The work resulted in the introduction of parasites of the sugarcane borer from British Guiana, Peru, and Trinidad, of the coconut thrips parasite *Dasyscapus parvipennis* from Trinidad, an account of which by the author has been noted (El. S. R., 77, p. 71), and of several effective predators of the coconut scale *Aspidiotus destructor* from Trinidad.

An examination of commercial calcium arsenates, O. A. NELSON and C. C. CASSIL (*Jour. Econ. Ent.*, 30 (1937), No. 3, pp. 474-478, fig. 1).—The results of analyses of various brands of commercial calcium arsenate on the United States market in 1936 by the only available method are reported in table form, and for comparison figures are given concerning the same brands as sold in previous years.

Particle size of commercial calcium arsenates by sedimentation analysis, L. D. GOODRICH (*Jour. Econ. Ent.*, 30 (1937), No. 3, pp. 466-474, figs. 4).—Determination of the particle-size distribution, the loose bulking value, the density, and the angle of slope for 22 commercial calcium arsenate samples is reported upon.

"The particle-size distribution and loose bulking value varied greatly, while the density and angle of slope showed less variation. The special grades produced by some of the companies were, in every case, finer than their standard grades. A comparison of the loose bulking values and the particle-size sedimentation showed little correlation. It is pointed out and substantiated by photographs that the bulking value so often used as a measure of particle size is unreliable and often entirely misleading. A correlation between density and particle size has been pointed out. The finest samples have the highest densities."

Stickers used with calcium and zinc arsenates, F. SHERMAN III (*Jour. Econ. Ent.*, 30 (1937), No. 3, pp. 398, 399).—Work by the Michigan Experiment Station with several stickers in commercial orchards during the season of 1936 has led the author to conclude that calcium and zinc arsenates combined with proper correctives and certain stickers will closely approximate lead arsenate as a poison for codling moth under average Michigan conditions.

Adherence and rate of settling of lead arsenate dusts for autogiro and airplane application, C. C. HAMILTON (*Jour. Econ. Ent.*, 30 (1937), No. 3, pp. 399-404).—Studies conducted by the New Jersey Experiment Stations for the purpose of modifying lead arsenate dusts in order that they could be satisfactorily applied by autogiro or airplane for the control of cankerworms or similar leaf-eating insects have shown that mixtures of oil with lead arsenate materially increased the adherence of the lead arsenate to oak foliage. "Fish oil gave the best adherence of the oils tested. Adherence of the lead arsenate was directly proportional to the amount of oil mixed with the lead arsenate. The rate of settling of lead arsenate could be increased by adding oil, and this rate of settling was directly proportional to the amount of oil added to the lead arsenate. Rate of settling of mixtures of Celite, oil, and lead arsenate was increased as the amount of oil was increased. Within limits the finer the particles of Celite the slower the settling of the dust mixtures. The finer the particles of Celite the better the distribution of the dust mixtures on the glass plates. The physical properties of the dust from the standpoint of rate of settling and adherence to glass plates were improved by adding Celite to the oil and lead arsenate mixtures."

Stickers and spreaders used in lead arsenate sprays for codling moth control, S. W. HARMAN (*Jour. Econ. Ent.*, 30 (1937), No. 3, pp. 404-407, fig. 1).—In tests made by the New York State Experiment Station during the season

of 1936 with various spreading and sticking agents used with lead arsenate sprays for combating heavy infestations of the codling moth, soybean flour gave the most satisfactory results. Used at the rate of 1 lb. in 100 gal. in combination with lead arsenate and hydrated lime, it produced a heavy, even coating of spray residue on the fruit which gave the most effective control and was removed from the picked fruit without difficulty.

Five years' experiments with lead arsenate-summer oil in codling moth control, B. F. DRIGGERS (*Jour. Econ. Ent.*, 30 (1937), No. 3, pp. 407-413).—A spray schedule of oil and lead arsenate for codling moth control was compared by the New Jersey Experiment Stations with a spray schedule of lead arsenate-lime-milk on several varieties of apples over a 5-yr. period at Moorestown and Glassboro. "No cumulative injury from the use of the oil has been observed to date. More foliage injury of a seasonal nature was observed on oil-lead arsenate-sprayed plats than on lime-lead arsenate-sprayed plats. This injury was not sufficiently pronounced, however, to vitiate the improved codling moth control observed. The use of oil with lead arsenate at the peaks of egg deposition improved the codling moth control over a schedule of lead arsenate-lime-milk. An oil emulsion used with lead arsenate gave slightly better control than a miscible oil used with lead arsenate. Three yr. of tests with home-made oil emulsions used with lead arsenate gave control of codling moth slightly better than that obtained with a commercial oil emulsion and lead arsenate, with no difference observable in fruit or foliage injury. The results show that summer oils have a place in the apple spray program in the heavily infested orchards in the two-brood area of southern New Jersey."

Effect of certain codling moth spray schedules on other orchard insects, C. R. CUTRIGHT (*Jour. Econ. Ent.*, 30 (1937), No. 3, pp. 413-417).—The use by the Ohio Experiment Station of phenothiazine in the experimental control program throughout the season of 1936 on several varieties of apple failed to control satisfactorily the codling moth, European red mite, and plum curculio but reduced the population of the apple aphid. "Oil-orthonicotine controlled green apple aphid and red mite, but injury by curculio and codling moth was severe. When lead arsenate was used in the calyx and followed by either phenothiazine or oil-orthonicotine schedules, control of codling moth, and particularly plum curculio, was greatly improved over the all-season use of these materials."

Tests of cattle fly sprays by the "one-half cow" method, D. MACCREARY and A. H. GORDIN (*Jour. Econ. Ent.*, 30 (1937), No. 3, pp. 478-482).—Data pertaining to the "one-half cow" method of testing cattle fly sprays are contributed from the Delaware Experiment Station. It is concluded that, while the validity of the method is open to question, if valid certain advantages are offered. A significant difference in the percentage of stable flies on the treated side was obtained between certain sprays. Analysis of the data pertaining to horse flies indicates that these data are meaningless.

Relative toxicity of the cresols as demonstrated by tests with *Carassius auratus*, W. A. GERSDORFF (*Jour. Agr. Res.* [U. S.], 54 (1937), No. 6, pp. 469-478, figs. 2).—A further study (E. S. R., 77, p. 69) made of the toxicity of the cresols (*o*-cresol, *m*-cresol, and *p*-cresol) with respect to concentration and survival time at 27° C., the results being compared with each other and with those for phenol and rotenone, is reported.

"Goldfish of the same lot, weighing approximately from 6 to 7.5 g each, were used as the test animals. The type of toxic action of the cresols was found to be similar to that of phenol. According to the minimum product of concentration and survival time, which measures toxicity at its range of

most powerful action, *m*-cresol is slightly less toxic than phenol, *o*-cresol is one-fifth more toxic, and *p*-cresol is nearly twice as toxic. Phenol, according to this measure, is only 0.003 as toxic as rotenone. The phenolic compounds do not differ much at the extremes of their ranges of toxic action. They differ mainly in the acceleration of this action with increase in concentration. Four methods of comparison in the range of greatest acceleration show that the compounds bear the following ratios of toxicity: *m*-cresol 1.0, phenol 1.1, *o*-cresol 1.3, and *p*-cresol 2.0. The same criteria show rotenone to be about 360 times as toxic as *m*-cresol. If time is not considered in the measure of comparison, and the compounds are compared according to concentrations necessary to kill under certain conditions, the values for the relative toxicity of the phenolic compounds are changed but little, if at all, but rotenone is favored to such an extent that its relative toxicity becomes 3,000 times that of *m*-cresol."

"The relative toxicity of these phenolic compounds according to the minimum lethal dose by subcutaneous injection found by other investigators for the rabbit, mouse, cat, rat, and guinea pig is close to that given above."

A list is given of 21 references to the literature.

Karaya gum in nicotine sprays, C. O. EDDY and C. M. MEADOWS (*Jour. Econ. Ent.*, 30 (1937), No. 3, pp. 430-432).—In experiments conducted first at the Kentucky Experiment Station (E. S. R., 76, p. 67) and later at the Louisiana Experiment Station in which *Tritogenaphis ambrosiae* (Thomas) on the great ragweed (*Ambrosia trifida*) was found to be a difficult aphid to kill with nicotine sulfate-soap spreader combinations, karaya gum greatly increased their effectiveness. By using the gum 1:500, one-fifth to one-third of the nicotine sulfate was effective.

In similar experiments with the bean aphid, nicotine sulfate-soap spreader combinations killed as effectively at 1:2,000 with karaya gum (1:500) as at 1:800 without the karaya gum. Karaya gum-soap spreader combinations without nicotine were ineffective.

Grenz radiographs of sulfur dispersion on foliage, G. F. MACLEOD and H. F. SHERWOOD (*Jour. Econ. Ent.*, 30 (1937), No. 3, pp. 395-398, figs. 3).—The need for a rapid, accurate method of depicting sulfur residues on foliage, which arose in the course of some general investigations of sulfur as an insecticide, led to the preliminary tests with Grenz-ray radiography here briefly reported. The work has indicated that it will provide an accurate and rapid method.

Rotenone-bearing plants and pyrethrum, F. L. CAMPBELL (*Ohio Veg. Growers Assoc. Proc.*, 22 (1937), pp. 11-18).—This includes a tabular comparative summary of information on rotenone-bearing plants and pyrethrum.

Results of experimental work with rotenone-bearing materials for the control of vegetable insects, N. F. HOWARD and H. C. MASON (*Ohio Veg. Growers Assoc. Proc.*, 22 (1937), pp. 19-24).—A practical discussion of the value of rotenone-bearing materials in combating vegetable insects.

An annotated list of the dragonflies (Odonata) of Ohio, D. J. BORROR (*Ohio Jour. Sci.*, 37 (1937), No. 3, pp. 185-196).—One hundred and twenty-seven forms are listed and records given of the counties in which they are known to occur.

Preliminary report on termites and termite damage in Trinidad, West Indies, A. M. ADAMSON (*Trop. Agr. [Trinidad]*, 14 (1937), No. 5, pp. 141-149, pls. 2).—Brief notes are given on the occurrence, habits, and probable economic status of the principal genera and species of termites of Trinidad, where over 30 species, representing some 20 genera, have been collected.

The mechanism of respiration of locusts and its bearing on the problem of inhalation of poison dusts, A. G. HAMILTON (*Bul. Ent. Res.*, 28 (1937), No. 1, pp. 53-68, figs. 2).—Measurements made of the spiracles and the tracheae of fifth instar hoppers and adults of *Locusta* and adults of *Schistocerca* have shown that particles of dust which have passed a 300 British standard sieve (i. e., under 0.053 mm in diameter) are small enough to enter all the spiracles, and that the particles which have passed a 150 British standard sieve (i. e., under 0.104 mm in diameter) can enter spiracles 1 to 4 and 10.

"It has been proved by the presence of particles of dust in the respective spiracles that spiracles 1 to 4 are inspiratory in function and spiracles 5 to 9 expiratory under all conditions, while the function of spiracle 10 is expiratory when the locust is flying and inspiratory when it is motionless. The quantity of dust present in the tracheae increases with the length of exposure to the cloud of dust; the quantity present after 10 seconds' exposure is not regarded as sufficient to kill the locust. The action of external poisons is thought to be by direct penetration of the integument or through the nerve endings or both. The results given in this paper suggest that further work on the action of poison dusts should be concentrated on the investigation of direct penetration of the integument and of the nerve action, rather than poisoning through the respiratory system."

The hollyhock thrips *Liothrips varicornis* Hood, S. F. BAILEY (*Jour. Econ. Ent.*, 30 (1937), No. 3, pp. 448-450, fig. 1).—Observations of *L. varicornis*, which has come to attention in California, are reported. This thrips appears to be limited to a semiarid climate and is found principally on the hollyhock. It does not require control measures because of the short growing season of the host plant and its minor importance as a pest.

Effect of different spreaders on thrips control by nicotine, C. O. EDDY and S. S. SHARP (*Jour. Econ. Ent.*, 30 (1937), No. 3, pp. 427-430).—In observations by the Louisiana Experiment Station the tobacco thrips, flower thrips, and onion thrips were found to injure garden and truck crops in that State. The tobacco thrips was by far the most destructive, especially to shallots, onions, and cabbages, and was used in the toxicity tests. The experiments reported have shown that the failure of spray mixtures containing nicotine sulfate to kill tobacco thrips is due to a deficiency in several spreaders which is corrected by the addition of potassium hydroxide. Karaya gum added to the sprays markedly increased their effectiveness.

Two hemipterous enemies of the Mexican bean beetle in Ohio, W. C. STEHR and W. FARRELL (*Ohio Jour. Sci.*, 36 (1936), No. 6, pp. 332, 333).—Notes are given on two predatory enemies of the Mexican bean beetle, namely, the pentatomid bug *Perillus circumcinctus* Stål, the female of which was found feeding on the adult beetle, and the wheel bug, the nymph of which fed on both the larva and adult beetle.

Histological studies of the digestive system of the squash bug, *Anasa tristis* DeG. (Hemiptera, Coreidae), E. P. BREAKER (*Ann. Ent. Soc. Amer.*, 29 (1936), No. 4, pp. 561-577, figs. 26).—This contribution on histological studies of the alimentary canal and its appendages and the salivary glands is presented with a list of 21 references to the literature cited.

Experiments to control hairy chinch bug infesting turf on Long Island, G. F. MACLEOD and K. E. MAXWELL (*Jour. Econ. Ent.*, 30 (1937), No. 3, pp. 432-437, figs. 2).—A report is made of experimental control work with the two broods of the hairy chinch bug on Long Island in which applications for the first brood were made during the first half of June and those for the second during the first half of August, after most of the eggs had hatched but before the young

bugs caused damage. Satisfactory control of heavy infestations was obtained "by each of the following materials, using two applications against each brood: Tobacco dust containing 1 percent nicotine or cube dust containing 1 percent rotenone at the rate of 25 lb. to 1,000 sq. ft. for each application, or a spray consisting of 40 percent nicotine sulfate 1:400 with 40 percent potassium oleate soap 1:100 applied at the rate of about 240 gal. to 1,000 sq. ft. In some cases one application gave adequate control. Two applications against each brood were more effective than one in reducing populations, and one application of 50 lb. of dust was more effective than one of 25 lb. to 1,000 sq. ft. Tobacco and rotenone dusts gave consistently better results than the nicotine-soap sprays, and the latter caused burning in each case. Tobacco dust was equal or superior to the other materials and was more satisfactory from the standpoint of cost. The evidence indicated that the tobacco dust need not be watered in. In an experiment dealing with a light infestation of chinch bugs, tobacco dust containing 0.75 percent nicotine and cube dust containing 0.5 percent rotenone gave effective control."

White coating on foliage a repellent for potato leafhopper, E. I. McDANIEL (*Jour. Econ. Ent.*, 30 (1937), No. 3, pp. 454-457).—Field experiments (E. S. R., 75, p. 511) conducted in Michigan in 1935 and 1936 on dahlia, potato, and alfalfa have shown that the potato leafhopper is repelled by a white, inert coating, such as infusorial earth, talc, and flour, on the foliage.

Food plants of the United States forms of the leafhoppers of the genus *Agalliopsis*, E. D. BALL (*Ann. Ent. Soc. Amer.*, 29 (1936), No. 4, pp. 650-655).—An account is given of the species of *Agalliopsis* occurring north of Mexico, with notes on the food plants of the 15 species recognized.

The control of froghopper blight, A. PICKLES (*Trop. Agr. [Trinidad]*, 14 (1937), No. 1, pp. 5-9).—A discussion of the control problem in the West Indies.

Pea aphid control in Maryland, C. GRAHAM (*Jour. Econ. Ent.*, 30 (1937), No. 3, pp. 439-443).—Five years' control work with the pea aphid, which in 1932 seriously threatened the pea industry of Garrett County, has shown that soap and nicotine sprays will give a large decrease in aphid infestation and an increase in the yield of shelled peas ranging from 13.2 to 104.9 percent over unsprayed peas.

"One year's experience with derris dust containing rotenone without spreader showed a slight decrease in aphid infestation and no increase in yield of peas over the unsprayed plats. The next year's experience with derris dust containing rotenone with spreader showed a decrease in aphid infestation in those plats that had an initial infestation and an increase in yield of peas ranging from 128.3 to 404 percent over the unsprayed plats. Highest yields, however, were from plats having no initial infestation. From the information obtained in these experiments it appears that the correct time to make the first application of spray is when the first aphids appear in the field. If the aphids come in about 10 days before the blooming period, it is advisable to apply a second application at the time the peas begin to bloom. However, if the aphid infestation starts at blossoming time only one application is necessary or economically useful."

Descriptions of some rabbit brush and willow aphids, G. F. KNOWLTON and C. F. SMITH (*Ann. Ent. Soc. Amer.*, 29 (1936), No. 4, pp. 776-778, figs. 2).—Contributing from the Utah Experiment Station, *Ovariella hendersoni* from *Salix* and *Aspidaphis adjuvans rowei* from *Chrysothamnus*, both from Utah. are described as new to science.

Additions and corrections to the "Aphidae of Colorado", M. A. PALMER (*Ann. Ent. Soc. Amer.*, 29 (1936), No. 4, pp. 729-748, figs. 21).—This contribution

from the Colorado Experiment Station, which supplements the synopsis of the Aphididae of Colorado, by Gillette and Palmer (E. S. R., 72, p. 659), furnishes information on the morphology, classification, and distribution of many forms, and includes an additional host plant list of records.

The rhododendron whitefly and its control, R. LATTA (U. S. Dept. Agr. Circ. 429 (1937), pp. 8, pls. 4, figs. 3).—This contribution deals with studies of the rhododendron white fly *Dialeurodes chittendeni* Laing, now prevalent in parts of England, but only recently discovered in the United States, having been intercepted in 1932 on rhododendrons imported from England. It appeared in 1933 at Seattle, Wash., and in 1934 on Long Island, N. Y., on rhododendrons imported from England. It was discovered in 1935 to occur on native rhododendrons growing wild in eastern Tennessee and in 1936 on plants shipped from White Sulphur Springs, W. Va., and Stroudsburg and Germantown, Pa. There are now well-established infestations near Seattle and Tacoma, Wash., and on Vancouver Island and in the Fraser River Valley, British Columbia. The account, which is presented as a source of information to nurserymen and gardeners, reports briefly on studies of the pest conducted chiefly in the Pacific Northwest.

This white fly seriously impairs the ornamental value of susceptible species and varieties of rhododendrons, the susceptibility to attack of varieties varying because of physical differences in the structure of their leaf surfaces. It was found that in western Washington there is "only one generation a year, which corresponds with conditions reported in England. The overwintering forms are principally the second- and third-instar larvae. The natural spread from plant to plant is slow because the adults apparently prefer to remain on the plant on which they developed. Oil sprays can be successfully used for the immature stages, a 2-percent spray giving satisfactory control, but twice that strength is desirable if eradication is attempted. Nicotine, either as a spray or dust, can be used to reduce adult populations."

Bemisia nigeriensis Corb., a vector of cassava mosaic in southern Nigeria, F. D. GOLING (Trop. Agr. [Trinidad], 13 (1936), No. 7, pp. 182-186).—In reporting further,^{*} transmission experiments with *B. nigeriensis* have confirmed the earlier conclusion and proved that this species is a vector of cassava mosaic. In two experiments conducted, mosaic symptoms appeared 27 days after the adult *Bemisia* had been placed in chimneys, each containing a healthy plant. The maximum intervals between the introduction of *Bemisia* and the first appearance of mosaic symptoms were 13, 19, and 21 days, respectively. The attempted transfer of mosaic from cassava to *Manihot glaziovii* and *Euphorbia heterophylla* resulted negatively.

Studies on the transmission of pea virus 2 by aphids, H. T. OSBORN (Phytopathology, 27 (1937), No. 5, pp. 589-603, figs. 4).—In experiments conducted, the mosaic pea disease virus, designated as pea virus 2, was transmitted by both nymphs and adults and by single individuals of the potato aphid, the bean aphid, and the pea aphid. "It was found that colonies of each of these aphids are able to acquire the virus during a feeding period of 5 min. on a diseased plant and are able to transmit it to a healthy plant during a 5-min. period immediately following. Some colonies lost the virus during a period of 15 min. on healthy plants. Retention of the virus for more than 1 hr. was not demonstrated in any colonies allowed to feed continuously on healthy plants for 1 hr. When held without access to food, the bean aphid was shown to retain the virus for 5 hr., the pea aphid for 8 hr., and the potato aphid in one instance for 24 hr. No incubation period of the virus was observed in colonies

^{*} Trop. Agr. [Trinidad], 12 (1935), No. 8, p. 215.

of the pea, potato, or bean aphids that were fed for 1 day on diseased plants and were then transferred to a succession of healthy plants for a total period of 14 days."

Notes on the yellow aphid of sugar-cane *Sipha flava* Forbes, F. A. SQUIRE (*Trop. Agr. [Trinidad]*, 14 (1937), No. 1, pp. 3, 4).—Notes on the biology of *S. flava* and means for its control are presented.

The immature stages of some Minnesota Trichoptera, W. A. ELKINS (*Ann. Ent. Soc. Amer.*, 29 (1936), No. 4, pp. 656-681, pls. 6).—Descriptions are given of the immature stages of eight species of Trichoptera studied in Minnesota.

Lineodes integra Zell., a potential pest of greenhouse tomatoes, C. C. COMPTON (*Jour. Econ. Ent.*, 30 (1937), No. 3, pp. 451-454, fig. 1).—This lepidopteran, not previously recorded as a pest of the tomato crop, has been found capable of causing severe damage to tomatoes grown in the greenhouse. All parts of the plants above the ground are subject to attack, the principal damage being caused by feeding of the larvae on the fruit.

"A sulfur-lead dust made up of 85 parts by weight of 300-mesh dusting sulfur and 15 parts by weight of lead arsenate gave the most satisfactory control. Arsenicals are not recommended when the fruit is ripening unless the fruit is to be washed. A derris dust containing 0.5 percent rotenone with talc as a diluent gave commercial control under greenhouse conditions. A pyrethrum spray containing 6 percent pyrethrum extractives was effective in killing all larvae thoroughly wet with the spray. The expense was greater than with the dusts."

[A pyralid enemy of cauliflower in the West Indies], R. C. WOOD and H. M. JAMES (*Trop. Agr. [Trinidad]*, 13 (1936), No. 8, pp. 219, 220).—Observations of a severe attack of young cauliflower plants by the caterpillars of *Hellula phidilealis*, its most important pest, life history notes, and means of control in the West Indies are presented.

Tests with bait and light to trap codling moth, H. N. WORTHLEY and J. E. NICHOLAS (*Jour. Econ. Ent.*, 30 (1937), No. 3, pp. 417-422).—Tests commenced by the Pennsylvania Experiment Station in 1934 with a view to developing a trap equally as effective as, but less expensive than, that described by Parrott and Collins (*El. S. R.*, 73, p. 75) are reported upon. The tests conducted in 1934 and 1935 have shown that the effectiveness of bait traps may be greatly increased by suspending them underneath 75-w lights.

"Results obtained in three seasons appear to show that a trap costing \$1.50 to make, and consisting of a light and reflector suspended above molasses-water bait in a pan 12 in. in diameter, is more effective in killing codling moth adults than an electrocuting light trap that sells for about \$15. . . . Employed in commercial orchards to reduce codling moth populations, the combination bait and light trap would be somewhat more expensive to operate than the electrocuting trap. The latter is automatic, while the former must be cleaned frequently and recharged with bait about every 10 days. However, the cost of bait and labor would scarcely equal interest on the extra investment in the electrocuting traps. Preliminary tests with the trapping light globes are encouraging, and means of increasing their effectiveness should be sought. The use of Anethol as an attractant with bait in 1934 increased the catch of female moths more than five times."

Effects of light traps on a codling moth infestation: A consideration of four years' data, D. L. COLLINS and W. MACHADO (*Jour. Econ. Ent.*, 30 (1937), No. 3, pp. 422-427, figs. 3).—The data on codling moth injury and population in an apple orchard equipped with light traps, based upon work by the New York

State Experiment Station, Cornell University, and U. S. D. A. Bureau of Entomology and Plant Quarantine cooperating over a period of 4 consecutive years, are here assembled and compared. The charts and data presented indicate "that the light traps exerted an influence on the codling moth infestation sufficient to be reflected in a measurable decrease in injury to the fruit. An evaluation of this influence on the basis of the different methods of comparison used leads to the inference that, under the given experimental conditions, the control achieved by light traps was comparable to that secured by the application of two cover sprays of lead arsenate."

Utilizing parasites in controlling the oriental fruit moth, D. M. DANIEL (*Ann. Ent. Soc. Amer.*, 29 (1936), No. 4, pp. 640-644).—Contributing from the New York State Experiment Station, a brief account is given of the progress of *Macrocentrus ancyllivorus* Roh. as a parasite of the oriental fruit moth following its introduction from New Jersey and liberation in western New York, commenced in 1928. Each year since 1929 the host individuals constituting the populations of the oriental fruit moth in Niagara County, N. Y., have become more widely separated by reason of the reduced population, and each year *M. ancyllivorus* has been able to find and successfully attack a larger proportion of the host larvae.
